## 8M-BIT [x 1 / x 2] CMOS SERIAL FLASH

#### **FEATURES**

#### **GENERAL**

- Single Power Supply Operation
  - 2.7 to 3.6 volt for read, erase, and program operations
- Serial Peripheral Interface compatible -- Mode 0 and Mode 3
- 8,388,608 x 1 bit structure or 4,194,304 x 2 bits (Dual Output mode) structure
- · 256 Equal Sectors with 4K byte each
  - Any Sector can be erased individually
- · 16 Equal Blocks with 64K byte each
  - Any Block can be erased individually
- · Program Capability
  - Byte base
  - Page base (256 bytes)
- Latch-up protected to 100mA from -1V to Vcc +1V

#### **PERFORMANCE**

- High Performance
  - Fast access time: 86MHz serial clock
  - Serial clock of Dual Output mode: 80MHz
  - Fast program time: 1.4ms(typ.) and 5ms(max.)/page
  - Byte program time: 9us (typical)
  - Fast erase time: 60ms(typ.) /sector; 0.7s(typ.) /block
- Low Power Consumption
  - Low active read current: 12mA(max.) at 86MHz
  - Low active programming current: 20mA (max.)
  - Low active erase current: 20mA (max.)
  - Low standby current: 25uA (max.)
  - Deep power-down mode 5uA (typical)
- Typical 100,000 erase/program cycles
- · 20 years of data retention

#### **SOFTWARE FEATURES**

- Input Data Format
  - 1-byte Command code
- Advanced Security Features
  - Block lock protection

The BP2-BP0 status bit defines the size of the area to be software protection against program and erase instructions

- Additional 512 bit secured OTP for unique identifier
- · Auto Erase and Auto Program Algorithm
  - Automatically erases and verifies data at selected sector
  - Automatically programs and verifies data at selected page by an internal algorithm that automatically times the program pulse widths (Any page to be programed should have page in the erased state first)
- Status Register Feature
- Electronic Identification
  - JEDEC 1-byte manufacturer ID and 2-byte device ID
  - RES command for 1-byte Device ID

- REMS command for 1-byte manufacturer ID and 1-byte device ID
- Support Serial Flash Discoverable Parameters (SFDP) mode

#### HARDWARE FEATURES

- PACKAGE
  - 8-pin SOP (150mil)
  - 8-pin SOP (200mil)
  - 8-pin PDIP (300mil)
  - 8-land WSON (6x5mm)
  - 8-land USON (4x4mm)
  - All devices are RoHS Compliant and Halogen-free

#### **GENERAL DESCRIPTION**

The device feature a serial peripheral interface and software protocol allowing operation on a simple 3-wire bus. The three bus signals are a clock input (SCLK), a serial data input (SI), and a serial data output (SO). Serial access to the device is enabled by CS# input.

When it is in Dual Output read mode, the SI and SO pins become SIO0 and SIO1 pins for data output.

The device provides sequential read operation on whole chip.

After program/erase command is issued, auto program/erase algorithms which program/erase and verify the specified page or sector/block locations will be executed. Program command is executed on byte basis, or page basis, or word basis for erase command is executes on sector, or block, or whole chip basis.

To provide user with ease of interface, a status register is included to indicate the status of the chip. The status read command can be issued to detect completion status of a program or erase operation via WIP bit.

Advanced security features enhance the protection and security functions, please see security features section for more details.

When the device is not in operation and CS# is high, it is put in standby mode.

The device utilizes Macronix's proprietary memory cell, which reliably stores memory contents even after typical 100,000 program and erase cycles.

## **PIN CONFIGURATIONS**

## 8-PIN SOP (200mil, 150mil)

## 8-PIN PDIP (300mil)

## 8-LAND WSON (6x5mm), USON (4x4mm)

## **PIN DESCRIPTION**

SYMBOL	DESCRIPTION
CS#	Chip Select
SI/SIO0	Serial Data Input (for 1 x I/O)/ Serial Data
31/3100	Input & Output (for Dual Output mode)
SO/SIO1	Serial Data Output (for 1 x I/O)/ Serial Data
30/3101	Output (for Dual Output mode)
SCLK	Clock Input
WP#	Write protection
HOLD#	Hold, to pause the device without
HOLD#	deselecting the device
VCC	+ 3.3V Power Supply
GND	Ground

## **BLOCK DIAGRAM**

## **MEMORY ORGANIZATION**

**Table 1. Memory Organization** 

Block	Sector	Address Range		
	255	0FF000h	0FFFFFh	
15	:	:	:	
	240	0F0000h	0F0FFFh	
	239	0EF000h	0EFFFFh	
14	:	:	:	
	224	0E0000h	0E0FFFh	
:	:	:	:	
:	:	:	:	
	15	00F000h	00FFFFh	
	:	:	:	
0	3	003000h	003FFFh	
	2	002000h	002FFFh	
	1	001000h	001FFFh	
	0	000000h	000FFFh	

#### **DEVICE OPERATION**

- 1. Before a command is issued, status register should be checked to ensure device is ready for the intended operation.
- When incorrect command is inputted to this LSI, this LSI becomes standby mode and keeps the standby mode until next CS# falling edge. In standby mode, SO pin of this LSI should be High-Z. The CS# falling time needs to follow tCHCL spec.
- 3. When correct command is inputted to this LSI, this LSI becomes active mode and keeps the active mode until next CS# rising edge. The CS# rising time needs to follow tCLCH spec.
- 4. Input data is latched on the rising edge of Serial Clock(SCLK) and data shifts out on the falling edge of SCLK. The difference of Serial mode 0 and mode 3 is shown in Figure 1.
- 5. For the following instructions:RDID, RDSR, RDSCUR, READ, FAST\_READ, RDSFDP, DREAD, RES, and REMS the shifted-in instruction sequence is followed by a data-out sequence. After any bit of data being shifted out, the CS# can be high. For the following instructions: WREN, WRDI, WRSR, SE, BE, CE, PP, RDP, DP, ENSO, EXSO,and WRSCUR, the CS# must go high exactly at the byte boundary; otherwise, the instruction will be rejected and not executed.
- 6. During the progress of Write Status Register, Program, Erase operation, to access the memory array is neglected and not affect the current operation of Write Status Register, Program, Erase.

Figure 1. Serial Modes Supported

#### Note:

CPOL indicates clock polarity of Serial master, CPOL=1 for SCLK high while idle, CPOL=0 for SCLK low while not transmitting. CPHA indicates clock phase. The combination of CPOL bit and CPHA bit decides which Serial mode is supported.

P/N: PM1613 REV. 1.3, SEP. 05, 2013

#### **DATA PROTECTION**

During power transition, there may be some false system level signals which result in inadvertent erasure or programming. The device is designed to protect itself from these accidental write cycles.

The state machine will be reset as standby mode automatically during power up. In addition, the control register architecture of the device constrains that the memory contents can only be changed after specific command sequences have completed successfully.

In the following, there are several features to protect the system from the accidental write cycles during VCC power-up and power-down or from system noise.

- Valid command length checking: The command length will be checked whether it is at byte base and completed
  on byte boundary.
- Write Enable (WREN) command: WREN command is required to set the Write Enable Latch bit (WEL) before other command to change data. The WEL bit will return to reset stage under following situation:
  - Power-up
  - Write Disable (WRDI) command completion
  - Write Status Register (WRSR) command completion
  - Page Program (PP) command completion
  - Sector Erase (SE) command completion
  - Block Erase (BE) command completion
  - Chip Erase (CE) command completion
- Deep Power Down Mode: By entering deep power down mode, the flash device also is under protected from writing all commands except Release from deep power down mode command (RDP) and Read Electronic Signature command (RES).
- Advanced Security Features: there are some protection and security features which protect content from inadvertent write and hostile access.

#### I. Block lock protection

- The Software Protected Mode (SPM):

MX25L8006E: use (BP2, BP1, BP0) bits to allow part of memory to be protected as read only. The proected area definition is shown as table of "Protected Area Sizes", the protected areas are more flexible which may protect various area by setting value of BP0-BP2 bits.

Please refer to table of "protected area sizes".

- The Hardware Proteced Mode (HPM) uses WP# to protect the MX25L8006E:BP2-BP0 bits and SRWD bit.

## MX25L8006E

**Table 2. Protected Area Sizes** 

	Status bit		Protect Level
BP2	BP1	BP0	MX25L8006E
0	0	0	0 (none)
0	0	1	1 (1block, block 15th)
0	1	0	2 (2blocks, block 14th-15th)
0	1	1	3 (4blocks, block 12th-15th)
1	0	0	4 (8blocks, block 8th-15th)
1	0	1	5 (All)
1	1	0	6 (All)
1	1	1	7 (All)

- **II. Additional 512 bit secured OTP** for unique identifier: to provide 512 bit one-time program area for setting device unique serial number Which may be set by factory or system customer. Please refer to table 3. 512 bit-secured OTP definition.
- Security register bit 0 indicates whether the chip is locked by factory or not.
- To program the 512 bit secured OTP by entering 512 bit secured OTP mode (with ENSO command), and going through normal program procedure, and then exiting 512 bit secured OTP mode by writing EXSO command.
- Customer may lock-down the customer lockable secured OTP by writing WRSCUR(write security register) command to set customer lock-down bit1 as "1". Please refer to table of "security register definition" for security register bit definition and table of "512 bit secured OTP definition" for address range definition.
- Note: Once lock-down whatever by factory or customer, it cannot be changed any more. While in 512 bit secured OTP mode, array access is not allowed.

Table 3. 512 bit Secured OTP Definition

Address range	Size	Standard Factory Lock	Customer Lock
xxxx00~xxxx0F	128-bit	ESN (electrical serial number)	Determined by customer
xxxx10~xxxx3F	384-bit	N/A	

#### **HOLD FEATURES**

HOLD# pin signal goes low to hold any serial communications with the device. The HOLD feature will not stop the operation of write status register, programming, or erasing in progress.

The operation of HOLD requires Chip Select (CS#) keeping low and starts on falling edge of HOLD# pin signal while Serial Clock (SCLK) signal is being low (if Serial Clock signal is not being low, HOLD operation will not start until Serial Clock signal being low). The HOLD condition ends on the rising edge of HOLD# pin signal while Serial Clock (SCLK) signal is being low (if Serial Clock signal is not being low, HOLD operation will not end until Serial Clock being low), see Figure 2.

**Figure 2. Hold Condition Operation** 

The Serial Data Output (SO) is high impedance, both Serial Data Input (SI) and Serial Clock (SCLK) are don't care during the HOLD operation. If Chip Select (CS#) drives high during HOLD operation, it will reset the internal logic of the device. To re-start communication with chip, the HOLD# must be at high and CS# must be at low.

## **COMMAND DESCRIPTION**

## **Table 4. COMMAND DEFINITION**

Command (byte)	WREN (write enable)	WRDI (write disable)	WRSR (write status register)	RDID (read identific- ation)	RDSR (read status register)	READ (read data)	FAST READ (fast read data)
1st byte	06 (hex)	04 (hex)	01 (hex)	9F (hex)	05 (hex)	03 (hex)	0B (hex)
2nd byte						AD1	AD1
3rd byte						AD2	AD2
4th byte						AD3	AD3
5th byte							Dummy
Action	sets the (WEL) write enable latch bit	(WEL) write	to write new values to the status register	outputs JEDEC ID: 1-byte Manufact-urer ID & 2-byte Device ID	to read out the values of the status register	n bytes read out until CS# goes high	n bytes read out until CS# goes high

			REMS (read	DREAD			
Command	RDSFDP	RES (read	electronic	(Double	SE (sector	BE (block	CE (chip
(byte)	(Read SFDP)	electronic ID)	manufacturer	Output Mode	erase)	erase)	erase)
			& device ID)	command)			
1st byte	5A (hex)	AB (hex)	90 (hex)	3B (hex)	20 (hex)	52 or D8 (hex)	60 or C7 (hex)
2nd byte	AD1	х	х	AD1	AD1	AD1	
3rd byte	AD2	х	х	AD2	AD2	AD2	
4th byte	AD3	х	ADD (Note 1)	AD3	AD3	AD3	
5th byte	Dummy			Dummy			
	Read SFDP	to read out	output the	n bytes read	to erase the	to erase the	to erase
	mode	1-byte Device	Manufacturer	out by Dual	selected	selected	whole chip
Action		ID	ID & Device	Output until	sector	block	
			ID	CS# goes			
				high			

Command (byte)	PP (page program)	RDSCUR (read security register)	WRSCUR (write security register)	ENSO (enter secured OTP)	EXSO (exit secured OTP)	DP (Deep	RDP (Release from deep power down)
1st byte	02 (hex)	2B (hex)	2F (hex)	B1 (hex)	C1 (hex)	B9 (hex)	AB (hex)
2nd byte	AD1						
3rd byte	AD2						
4th byte	AD3						
5th byte							
Action	to program the selected page	to read value of security register	to set the lock-down bit as "1" (once lock-down, cannot be updated)		to exit the 512 bit secured OTP mode	enters deep power down mode	release from deep power down mode

Note 1: ADD=00H will output the manufacturer ID first and ADD=01H will output device ID first.

Note 2: It is not recommended to adopt any other code not in the command definition table, which will potentially enter the hidden mode.

#### (1) Write Enable (WREN)

The Write Enable (WREN) instruction is for setting Write Enable Latch (WEL) bit. For those instructions like PP, SE, BE, CE, and WRSR, which are intended to change the device content, should be set every time after the WREN instruction setting the WEL bit.

The sequence is shown as Figure 11.

#### (2) Write Disable (WRDI)

The Write Disable (WRDI) instruction is for resetting Write Enable Latch (WEL) bit.

The sequence is shown as Figure 12.

The WEL bit is reset by following situations:

- Power-up
- Write Disable (WRDI) instruction completion
- Write Status Register (WRSR) instruction completion
- Page Program (PP) instruction completion
- Sector Erase (SE) instruction completion
- Block Erase (BE) instruction completion
- Chip Erase (CE) instruction completion

#### (3) Read Status Register (RDSR)

The RDSR instruction is for reading Status Register Bits. The Read Status Register can be read at any time (even in program/erase/write status register condition) and continuously. It is recommended to check the Write in Progress (WIP) bit before sending a new instruction when a program, erase, or write status register operation is in progress.

The sequence is shown as Figure 13.

The definition of the status register bits is as below:

**WIP bit.** The Write in Progress (WIP) bit, a volatile bit, indicates whether the device is busy in program/erase/write status register progress. When WIP bit sets to 1, which means the device is busy in program/erase/write status register progress. When WIP bit sets to 0, which means the device is not in progress of program/erase/write status register cycle.

**WEL bit.** The Write Enable Latch (WEL) bit, a volatile bit, indicates whether the device is set to internal write enable latch. When WEL bit sets to 1, which means the internal write enable latch is set, the device can accept program/erase/write status register instruction. When WEL bit sets to 0, which means no internal write enable latch; the device will not accept program/erase/write status register instruction. The program/erase command will be ignored and not affect value of WEL bit if it is applied to a protected memory area.

**BP2, BP1, BP0 bits.** The Block Protect (BP2-BP0) bits, non-volatile bits, indicate the protected area (as defined in table 2) of the device to against the program/erase instruction without hardware protection mode being set. To write the Block Protect (BP2-BP0) bits requires the Write Status Register (WRSR) instruction to be executed. Those bits define the protected area of the memory to against Page Program (PP), Sector Erase (SE), Block Erase (BE) and Chip Erase(CE) instructions (only if all Block Protect bits set to 0, the CE instruction can be executed).

**SRWD bit.** The Status Register Write Disable (SRWD) bit, non-volatile bit, is operated together with Write Protection (WP#) pin for providing hardware protection mode. The hardware protection mode requires SRWD sets to 1 and WP# pin signal is low stage. In the hardware protection mode, the Write Status Register (WRSR) instruction is no longer accepted for execution and the SRWD bit and Block Protect bits (BP2-BP0) are read only.

#### **Status Register**

bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
SRWD (status register write protect)	0	0	BP2 (level of protected block)	BP1 (level of protected block)	BP0 (level of protected block)	WEL (write enable latch)	WIP (write in progress bit)
1=status register write disable	0	0	(note 1)	(note 1)	(note 1)	1=write enable 0=not write enable	1=write operation 0=not in write operation
Non-volatile bit	0	0	Non-volatile bit	Non-volatile bit	Non-volatile bit	volatile bit	volatile bit

note 1: see the table "Protected Area Size".

#### (4) Write Status Register (WRSR)

The WRSR instruction is for changing the values of Status Register Bits. Before sending WRSR instruction, the Write Enable (WREN) instruction must be decoded and executed to set the Write Enable Latch (WEL) bit in advance. The WRSR instruction can change the value of Block Protect (BP2-BP0) bits to define the protected area of memory (as shown in table 1). The WRSR also can set or reset the Status Register Write Disable (SRWD) bit in accordance with Write Protection (WP#) pin signal. The WRSR instruction cannot be executed once the Hardware Protected Mode (HPM) is entered.

The sequence is shown as Figure 14.

The WRSR instruction has no effect on b6, b1, b0 of the status register.

The CS# must go high exactly at the byte boundary; otherwise, the instruction will be rejected and not executed. The self-timed Write Status Register cycle time (tW) is initiated as soon as Chip Select (CS#) goes high. The Write in Progress (WIP) bit still can be check out during the Write Status Register cycle is in progress. The WIP sets 1 during the tW timing, and sets 0 when Write Status Register Cycle is completed, and the Write Enable Latch (WEL) bit is reset.

## MX25L8006E

#### **Table 5. Protection Modes**

Mode	Status register condition	WP# and SRWD bit status	Memory
Software protection mode (SPM)	Status register can be written in (WEL bit is set to "1") and the SRWD, BP2-BP0 bits can be changed	WP#=1 and SRWD bit=0, or WP#=0 and SRWD bit=0, or WP#=1 and SRWD=1	The protected area cannot be program or erase.
Hardware protection mode (HPM)	The SRWD, BP2-BP0 of status register bits cannot be changed	WP#=0, SRWD bit=1	The protected area cannot be program or erase.

#### Note

As the above table showing, the summary of the Software Protected Mode (SPM) and Hardware Protected Mode (HPM).

#### Software Protected Mode (SPM):

- When SRWD bit=0, no matter WP# is low or high, the WREN instruction may set the WEL bit and can change the values of SRWD, BP2-BP0. The protected area, which is defined by BP2-BP0 is at software protected mode (SPM).
- When SRWD bit=1 and WP# is high, the WREN instruction may set the WEL bit can change the values of SRWD, BP2-BP0. The protected area, which is defined by BP2-BP0, is at software protected mode (SPM).

Note: If SRWD bit=1 but WP# is low, it is impossible to write the Status Register even if the WEL bit has previously been set. It is rejected to write the Status Register and not be executed.

### Hardware Protected Mode (HPM):

- When SRWD bit=1, and then WP# is low (or WP# is low before SRWD bit=1), it enters the hardware protected mode (HPM). The data of the protected area is protected by software protected mode by BP2-BP0 and hardware protected mode by the WP# to against data modification.

Note: to exit the hardware protected mode requires WP# driving high once the hardware protected mode is entered. If the WP# pin is permanently connected to high, the hardware protected mode can never be entered; only can use software protected mode via BP2-BP0.

<sup>1.</sup> As defined by the values in the Block Protect (BP2-BP0) bits of the Status Register, as shown in Table 1.

#### (5) Read Data Bytes (READ)

The read instruction is for reading data out. The address is latched on rising edge of SCLK, and data shifts out on the falling edge of SCLK at a maximum frequency fR. The first address byte can be at any location. The address is automatically increased to the next higher address after each byte data is shifted out, so the whole memory can be read out at a single READ instruction. The address counter rolls over to 0 when the highest address has been reached.

The sequence is shown as Figure 15.

#### (6) Read Data Bytes at Higher Speed (FAST\_READ)

The FAST\_READ instruction is for quickly reading data out. The address is latched on rising edge of SCLK, and data of each bit shifts out on the falling edge of SCLK at a maximum frequency fC. The first address byte can be at any location. The address is automatically increased to the next higher address after each byte data is shifted out, so the whole memory can be read out at a single FAST\_READ instruction. The address counter rolls over to 0 when the highest address has been reached.

The sequence is shown as Figure 16.

While Program/Erase/Write Status Register cycle is in progress, FAST\_READ instruction is rejected without any impact on the Program/Erase/Write Status Register current cycle.

#### (7) Dual Output Mode (DREAD)

The DREAD instruction enable double throughput of Serial Flash in read mode. The address is latched on rising edge of SCLK, and data of every two bits(interleave on 1l/2O pins) shift out on the falling edge of SCLK at a maximum frequency fT. The first address byte can be at any location. The address is automatically increased to the next higher address after each byte data is shifted out, so the whole memory can be read out at a single DREAD instruction. The address counter rolls over to 0 when the highest address has been reached. Once writing DREAD instruction, the data out will perform as 2-bit instead of previous 1-bit.

The sequence is shown as *Figure 17*.

While Program/Erase/Write Status Register cycle is in progress, DREAD instruction is rejected without any impact on the Program/Erase/Write Status Register current cycle.

The DREAD only perform read operation. Program/Erase /Read ID/Read status....operation do not support DREAD throughputs.

#### (8) Sector Erase (SE)

The Sector Erase (SE) instruction is for erasing the data of the chosen sector to be "1". The instruction is used for any 4K-byte sector. A Write Enable (WREN) instruction must execute to set the Write Enable Latch (WEL) bit before sending the Sector Erase (SE). Any address of the sector (see table 3) is a valid address for Sector Erase (SE) instruction. The CS# must go high exactly at the byte boundary (the latest eighth of address byte been latched-in); otherwise, the instruction will be rejected and not executed.

Address bits [Am-A12] (Am is the most significant address) select the sector address.

The sequence is shown as Figure 18.

The self-timed Sector Erase Cycle time (tSE) is initiated as soon as Chip Select (CS#) goes high. The Write in Progress (WIP) bit still can be check out during the Sector Erase cycle is in progress. The WIP sets 1 during the tSE timing, and sets 0 when Sector Erase Cycle is completed, and the Write Enable Latch (WEL) bit is reset. If the page is protected by BP2-BP0 bits, the Sector Erase (SE) instruction will not be executed on the page.

#### (9) Block Erase (BE)

The Block Erase (BE) instruction is for erasing the data of the chosen block to be "1". The instruction is used for 64K-byte sector erase operation. A Write Enable (WREN) instruction must execute to set the Write Enable Latch (WEL) bit before sending the Block Erase (BE). Any address of the block (see table 3) is a valid address for Block Erase (BE) instruction. The CS# must go high exactly at the byte boundary (the latest eighth of address byte been latched-in); otherwise, the instruction will be rejected and not executed.

The sequence is shown as Figure 19.

The self-timed Block Erase Cycle time (tBE) is initiated as soon as Chip Select (CS#) goes high. The Write in Progress (WIP) bit still can be check out during the Sector Erase cycle is in progress. The WIP sets 1 during the tBE timing, and sets 0 when Sector Erase Cycle is completed, and the Write Enable Latch (WEL) bit is reset. If the page is protected by BP2-BP0 bits, the Block Erase (BE) instruction will not be executed on the page.

#### (10) Chip Erase (CE)

The Chip Erase (CE) instruction is for erasing the data of the whole chip to be "1". A Write Enable (WREN) instruction must execute to set the Write Enable Latch (WEL) bit before sending the Chip Erase (CE). Any address of the sector (see table 3) is a valid address for Chip Erase (CE) instruction. The CS# must go high exactly at the byte boundary( the latest eighth of address byte been latched-in); otherwise, the instruction will be rejected and not executed.

The sequence is shown as Figure 20.

The self-timed Chip Erase Cycle time (tCE) is initiated as soon as Chip Select (CS#) goes high. The Write in Progress (WIP) bit still can be check out during the Chip Erase cycle is in progress. The WIP sets 1 during the tCE timing, and sets 0 when Chip Erase Cycle is completed, and the Write Enable Latch (WEL) bit is reset. If the chip is protected by BP2-BP0 bits, the Chip Erase (CE) instruction will not be executed. It will be only executed when BP2-BP0 all set to "0".

## (11) Page Program (PP)

The Page Program (PP) instruction is for programming the memory to be "0". A Write Enable (WREN) instruction must execute to set the Write Enable Latch (WEL) bit before sending the Page Program (PP). The last address byte (the 8 least significant address bits, A7-A0) should be set to 0 for 256 bytes page program. If A7-A0 are not all zero, transmitted data that exceed page length are programmed from the starting address (24-bit address that last 8 bit are all 0) of currently selected page. The CS# must keep during the whole Page Program cycle. The CS# must go high exactly at the byte boundary (the latest eighth of address byte been latched-in); otherwise, the instruction will be rejected and not executed. If the data bytes sent to the device exceeds 256, the last 256 data byte is programmed at the request page and previous data will be disregarded. If the data bytes sent to the device has not exceeded 256, the data will be programmed at the request address of the page. There will be no effort on the other data bytes of the same page.

The sequence is shown as Figure 21.

The self-timed Page Program Cycle time (tPP) is initiated as soon as Chip Select (CS#) goes high. The Write in Progress (WIP) bit still can be check out during the Page Program cycle is in progress. The WIP sets 1 during the tPP timing, and sets 0 when Page Program Cycle is completed, and the Write Enable Latch (WEL) bit is reset. If the page is protected by BP2-BP0 bits, the Page Program (PP) instruction will not be executed.

#### (12) Deep Power-down (DP)

The Deep Power-down (DP) instruction is for setting the device on the minimizing the power consumption (to entering the Deep Power-down mode), the standby current is reduced from ISB1 to ISB2). The Deep Power-down mode requires the Deep Power-down (DP) instruction to enter, during the Deep Power-down mode, the device is not active and all Write/Program/Erase instruction are ignored. When CS# goes high, it's only in standby mode not deep power-down mode. It's different from Standby mode.

The sequence is shown as Figure 22.

Once the DP instruction is set, all instruction will be ignored except the Release from Deep Power-down mode (RDP) and Read Electronic Signature (RES) instruction. (those instructions allow the ID being reading out). When Power-down, the deep power-down mode automatically stops, and when power-up, the device automatically is in standby mode. For RDP instruction the CS# must go high exactly at the byte boundary (the latest eighth bit of instruction code been latched-in); otherwise, the instruction will not executed. As soon as Chip Select (CS#) goes high, a delay of tDP is required before entering the Deep Power-down mode and reducing the current to ISB2.

#### (13) Release from Deep Power-down (RDP), Read Electronic Signature (RES)

The Release from Deep Power-down (RDP) instruction is terminated by driving Chip Select (CS#) High. When Chip Select (CS#) is driven High, the device is put in the Stand-by Power mode. If the device was not previously in the Deep Power-down mode, the transition to the Stand-by Power mode is immediate. If the device was previously in the Deep Power-down mode, though, the transition to the Stand-by Power mode is delayed by tRES2, and Chip Select (CS#) must remain High for at least tRES2(max), as specified in *Table 9*. Once in the Stand-by Power mode, the device waits to be selected, so that it can receive, decode and execute instructions.

RES instruction is for reading out the old style of 8-bit Electronic Signature, whose values are shown as table of ID Definitions. This is not the same as RDID instruction. It is not recommended to use for new design. For new design, please use RDID instruction. Even in Deep power-down mode, the RDP and RES are also allowed to be executed, only except the device is in progress of program/erase/write cycle; there's no effect on the current program/erase/write cycle in progress.

The sequence is shown in Figure 23 and Figure 24.

The RES instruction is ended by CS# goes high after the ID been read out at least once. The ID outputs repeatedly if continuously send the additional clock cycles on SCLK while CS# is at low. If the device was not previously in Deep Power-down mode, the device transition to standby mode is immediate. If the device was previously in Deep Power-down mode, there's a delay of tRES2 to transit to standby mode, and CS# must remain to high at least tRES2(max). Once in the standby mode, the device waits to be selected, so it can be receive, decode, and execute instruction.

The RDP instruction is for releasing from Deep Power Down Mode.

#### (14) Read Identification (RDID)

The RDID instruction is for reading the manufacturer ID of 1-byte and followed by Device ID of 2-byte. The MXIC Manufacturer ID and Device ID are listed as table of "ID Definitions".

The sequence is shown as Figure 25.

While Program/Erase operation is in progress, it will not decode the RDID instruction, so there's no effect on the cycle of program/erase operation which is currently in progress. When CS# goes high, the device is at standby stage.

#### (15) Read Electronic Manufacturer ID & Device ID (REMS)

The REMS instruction is an alternative to the Release from Power-down/Device ID instruction that provides both the JEDEC assigned manufacturer ID and the specific device ID.

The REMS instruction is very similar to the Release from Power-down/Device ID instruction. The instruction is initiated by driving the CS# pin low and shift the instruction code "90h" followed by two dummy bytes and one bytes address (A7~A0). After which, the Manufacturer ID for MXIC and the Device ID are shifted out on the falling edge of SCLK with most significant bit (MSB) first as shown in *Figure 26*. The Device ID values are listed in Table of ID Definitions. If the one-byte address is initially set to 01h, then the device ID will be read first and then followed by the Manufacturer ID. The Manufacturer and Device IDs can be read continuously, alternating from one to the other. The instruction is completed by driving CS# high.

**Table 6. ID DEFINITIONS** 

Command Type		MX25L8006E	
RDID Command	manufacturer ID	memory type	memory density
RDID Collinatio	C2	20	14
DES Command		electronic ID	
RES Command		13	
REMS	manufacturer ID	device ID	
REIVIS	C2	13	

#### (16) Enter Secured OTP (ENSO)

The ENSO instruction is for entering the additional 512 bit secured OTP mode. The additional 512 bit secured OTP is independent from main array, which may use to store unique serial number for system identifier. After entering the Secured OTP mode, and then follow standard read or program, procedure to read out the data or update data. The Secured OTP data cannot be updated again once it is lock-down.

Please note that WRSR/WRSCUR commands are not acceptable during the access of secure OTP region, once security OTP is lock down, only read related commands are valid.

#### (17) Exit Secured OTP (EXSO)

The EXSO instruction is for exiting the additional 512 bit secured OTP mode.

### (18) Read Security Register (RDSCUR)

The RDSCUR instruction is for reading the value of Security Register bits. The Read Security Register can be read at any time (even in program/erase/write status register/write security register condition) and continuously.

The sequence is shown as Figure 27.

The definition of the Security Register bits is as below:

**Secured OTP Indicator bit.** The Secured OTP indicator bit shows the chip is locked by factory before ex- factory or not. When it is "0", it indicates non- factory lock; "1" indicates factory- lock.

**Lock-down Secured OTP (LDSO) bit.** By writing WRSCUR instruction, the LDSO bit may be set to "1" for customer lock-down purpose. However, once the bit is set to "1" (lock-down), the LDSO bit and the 512 bit Secured OTP area cannot be update any more. While it is in 512 bit secured OTP mode, array access is not allowed.

**Table 7. SECURITY REGISTER DEFINITION** 

bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
х	х	х	х	x	х	LDSO (indicate if lock-down	Secured OTP indicator bit
reserved	reserved	reserved	reserved	reserved	reserved	0 = not lockdown 1 = lock-down (cannot program/erase OTP)	0 = nonfactory lock 1 = factory lock
volatile bit	non-volatile bit	non-volatile bit					

#### (19) Write Security Register (WRSCUR)

The WRSCUR instruction is for changing the values of Security Register Bits. Unlike write status register, the WREN instruction is not required before sending WRSCUR instruction. The WRSCUR instruction may change the values of bit1 (LDSO bit) for customer to lock-down the 512 bit Secured OTP area. Once the LDSO bit is set to "1", the Secured OTP area cannot be updated any more.

The CS# must go high exactly at the boundary; otherwise, the instruction will be rejected and not executed.

The sequence is shown as Figure 28.

## (20) Read SFDP Mode (RDSFDP)

The Serial Flash Discoverable Parameter (SFDP) standard provides a consistent method of describing the functional and feature capabilities of serial flash devices in a standard set of internal parameter tables. These parameter tables can be interrogated by host system software to enable adjustments needed to accommodate divergent features from multiple vendors. The concept is similar to the one found in the Introduction of JEDEC Standard, JESD68 on CFI.

The sequence of issuing RDSFDP instruction is CS# goes low→send RDSFDP instruction (5Ah)→send 3 address bytes on SI pin→send 1 dummy byte on SI pin→read SFDP code on SO→to end RDSFDP operation can use CS# to high at any time during data out.

SFDP is a standard of JEDEC. JESD216. v1.0.

#### Read Serial Flash Discoverable Parameter (RDSFDP) Sequence

Table a. Signature and Parameter Identification Data Values

Description	Comment	Add (h) (Byte)	DW Add (Bit)	Data (h/b) (Note1)	Data (h)
		00h	07:00	53h	53h
CEDD Cignoture	Fixed: F04446F2h	01h	15:08	46h	46h

## MX25L8006E

- Note 1: h/b is hexadecimal or binary.
- Note 2: **(x-y-z)** means I/O mode nomenclature used to indicate the number of active pins used for the opcode (x), address (y), and data (z). At the present time, the only valid Read SFDP instruction modes are: (1-1-1), (2-2-2), and (4-4-4)
- Note 3: Wait States is required dummy clock cycles after the address bits or optional mode bits.
- Note 4: **Mode Bits** is optional control bits that follow the address bits. These bits are driven by the system controller if they are specified. (eg,read performance enhance toggling bits)
- Note 5: 4KB=2^0Ch,32KB=2^0Fh,64KB=2^10h
- Note 6: 0xFFh means all data is blank ("1b").

#### **POWER-ON STATE**

The device is at below states when power-up:

- Standby mode ( please note it is not deep power-down mode)
- Write Enable Latch (WEL) bit is reset

The device must not be selected during power-up and power-down stage unless the VCC achieves below correct level:

- VCC minimum at power-up stage and then after a delay of tVSL
- GND at power-down

Please note that a pull-up resistor on CS# may ensure a safe and proper power-up/down level.

An internal power-on reset (POR) circuit may protect the device from data corruption and inadvertent data change during power up state.

For further protection on the device, if the VCC does not reach the VCC minimum level, the correct operation is not guaranteed. The read, write, erase, and program command should be sent after the below time delay:

- tVSL after VCC reached VCC minimum level

The device can accept read command after VCC reached VCC minimum and a time delay of tVSL.

Please refer to the figure of "power-up timing".

#### Note:

- To stabilize the VCC level, the VCC rail decoupled by a suitable capacitor close to package pins is recommended.(generally around 0.1uF)

#### **INITIAL DELIVERY STATE**

The device is delivered with the memory array erased: all bits are set to 1 (each byte contains FFh). The Status Register contains 00h (all Status Register bits are 0).

#### **ELECTRICAL SPECIFICATIONS**

#### **ABSOLUTE MAXIMUM RATINGS**

RATING		VALUE
Ambient Operating Temperature	Industrial grade	-40°C to 85°C
Storage Temperature		-65°C to 150°C
Applied Input Voltage		-0.5V to VCC+0.5V
Applied Output Voltage		-0.5V to VCC+0.5V
VCC to Ground Potential		-0.5V to 4.0V

#### NOTICE:

- 1. Stresses greater than those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent damage to the device. This is stress rating only and functional operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended period may affect reliability.
- 2. Specifications contained within the following tables are subject to change.
- 3. During voltage transitions, all pins may overshoot Vss to -2.0V and Vcc to +2.0V for periods up to 20ns, see Figure 3 and 4.

### Notes:

- 1. tCH + tCL must be greater than or equal to 1/ fC. For Fast Read, tCL/tCH=5.5/5.5.
- 2. Value guaranteed by characterization, not 100% tested in production.
- 3. Expressed as a slew-rate.
- 4. Only applicable as a constraint for a WRSR instruction when SRWD is set at 1.
- 5. Test condition is shown as Figure 5 & 6.
- 6. The CS# rising time needs to follow tCLCH spec and CS# falling time needs to follow tCHCL spec.

## **Timing Analysis**

P/N: PM1613 REV. 1.3, SEP. 05, 2013

Figure 29. Power-up Timing

Note: VCC (max.) is 3.6V and VCC (min.) is 2.7V.

**Table 10. Power-Up Timing** 

Symbol	Parameter	Min.	Max.	Unit
tVSL(1)	VCC(min) to CS# low	200		us

Note: 1. The parameter is characterized only.

### **OPERATING CONDITIONS**

## At Device Power-Up and Power-Down

AC timing illustrated in Figure 30 and Figure 31 are the supply voltages and the control signals at device power-up and power-down. If the timing in the figures is ignored, the device will not operate correctly.

During power-up and power down, CS# need to follow the voltage applied on VCC to keep the device not be selected. The CS# can be driven low when VCC reach Vcc(min.) and wait a period of tVSL.

Figure 30. AC Timing at Device Power-Up

Symbol	Parameter	Notes	Min.	Max.	Unit
tVR	VCC Rise Time	1	20	500000	us/V

#### Notes:

- 1. Sampled, not 100% tested.
- 2. For AC spec tCHSL, tSLCH, tDVCH, tCHDX, tSHSL, tCHSH, tSHCH, tCHCL, tCLCH in the figure, please refer to "AC CHARACTERISTICS" table.

# Figure 31. Power-Down Sequence

During power down, CS# need to follow the voltage drop on VCC to avoid mis-operation.

# MX25L8006E

## **ERASE AND PROGRAMMING PERFORMANCE**

Parameter	Min.	Typ. (1)	Max. (2)	Unit
Write Status Register Time		5	40	ms
Sector Erase Time		60	300	ms
Block Erase Time		0.7	2	s
Chip Erase Time		7	15	s
Byte Program Time (via page program command)		9	300	us
Page Program Time		1.4	5	ms
Erase/Program Cycle		100,000		cycles

#### Note:

- 1. Typical program and erase time assumes the following conditions: 25°C, 3.3V, and checkerboard pattern.
- 2. Under worst conditions of 85°C and 2.7V.
- 3. System-level overhead is the time required to execute the first-bus-cycle sequence for the programming command.
- 4. Erase/Program cycles comply with JEDEC: JESD-47 & JESD22-A117 standard.

## **DATA RETENTION**

Parameter	Condition	Min.	Max.	Unit
Data retention	55°C	20		years

## **LATCH-UP CHARACTERISTICS**

	Min.	Max.					
Input Voltage with respect to GND on all power pins, SI, CS#	-1.0V	2 VCCmax					
Input Voltage with respect to GND on SO	-1.0V	VCC + 1.0V					
Current	-100mA	+100mA					
Includes all pins except VCC. Test conditions: VCC = 3.0V, one pin at a time.

#### Note:

This package has an exposed metal pad underneath the package. It is recommended to leave the metal pad floating or to connect it to the same ground as the GND pin of the package. Do not connect the metal pad to any other voltage or signal line on the PCB. Avoid placing vias or traces underneath the metal pad. Connection of this metal pad to any other voltage or signal line can result in shorts and/or electrical malfunction of the device.
