

# LM2854 4A 500 kHz / 1 MHz Synchronous SIMPLE SWITCHER® Buck Regulator

Check for Samples: [LM2854](#)

## FEATURES

- Input Voltage Range of 2.95V to 5.5V
- Maximum Load Current of 4A
- Wide Bandwidth Voltage Mode Control Loop, Partial Internal Compensation
- Fixed Switching Frequency of 500 kHz or 1 MHz
- 35 mΩ Integrated MOSFET Switches
- Adjustable Output Voltage Down to 0.8V
- Optimized Reference Voltage Initial Accuracy and Temperature Drift
- External Soft-Start Control with Tracking Capability
- Enable Pin with Hysteresis
- Low Standby Current of 230 μA
- Pre-Biased Load Startup Capability
- Integrated UVLO, OCP and Thermal Shutdown
- 100% Duty Cycle Capability
- HTSSOP-16 Exposed Pad Package

## APPLICATIONS

- Low Voltage POL Regulation from 5V or 3.3V Rail
- Local Solution for FPGA/DSP/ASIC/μP Core or I/O Power
- Broadband Networking and Communications Infrastructure
- Portable Computing

## DESCRIPTION

The LM2854 PowerWise™ SIMPLE SWITCHER buck regulator is a 500 kHz or 1 MHz step-down switching voltage regulator capable of driving up to a 4A load with exceptional power conversion efficiency, line and load regulation, and output accuracy. The LM2854 can accept an input voltage rail between 2.95V and 5.5V and deliver an adjustable and highly accurate output voltage as low as 0.8V. Externally established soft-start with a small capacitor facilitates controlled start-up, and the LM2854 is capable of starting gracefully into a pre-biased output voltage. Partial internal compensation reduces the number of external passive components and PC board space typically necessary in a voltage mode buck converter application, yet preserving flexibility to deal with ceramic and/or electrolytic based load capacitors. Lossless cycle-by-cycle peak current limit is used to protect the load from an overcurrent or short-circuit fault, and an enable comparator simplifies sequencing applications. The LM2854 is available in an exposed pad HTSSOP-16 package that enhances the thermal performance of the regulator.

## Typical Application Circuit

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

### PIN DESCRIPTIONS

Pin Number	Name	Description
1	NC	Reserved for factory use, this pin should be connected to GND to ensure proper operation.
2,3,4	PGND	Power ground pins for the internal power switches. These pins should be connected together locally at the device and tied to the PC board ground plane.
5,6,7	PVIN	Input voltage to the power switches inside the device. These pins should be connected together at the device. A low ESR input capacitance should be located as close as possible to these pins.
8,9	NC	Reserved for factory use, these pins should be connected to GND to ensure proper operation.
10	AVIN	Analog input voltage supply that generates the internal bias. The UVLO circuit derives its input from this pin also. Thus, if the voltage on AVIN falls below the UVLO threshold, both internal FETs are turned off. It is recommended to connect PVIN to AVIN through a low pass RC filter to minimize the influence of input rail ripple and noise on the analog control circuitry. The series resistor should be 1Ω and the bypass capacitor should be a X7R ceramic type 0.1 μF to 1.0 μF.
11	EN	Active high enable input for the device. Typically, turn-on threshold is 1.23V with 0.15V hysteresis. An external resistor divider from PVIN can be used to effectively increase the UVLO turn-on threshold. If not used, the EN pin should be connected to PVIN.
12,13	SW	Switch node pins. This is the PWM output of the internal MOSFET power switches. These pins should be tied together locally and connected to the filter inductor.
14	SS	Soft-start control pin. An internal 2 μA current source charges an external capacitor connected between this pin and AGND to set the output voltage ramp rate during startup. This pin can also be used to configure the tracking feature.
15	AGND	Quiet analog ground for the internal bias circuitry.
16	FB	Feedback pin is connected to the inverting input of the voltage loop error amplifier. A 0.8V bandgap reference is connected to the non-inverting input of the error amplifier.
EXP	Exposed Pad	Exposed metal pad on the underside of the package with a weak electrical connection to PGND. It is recommended to connect this pad to the PC board ground plane in order to improve thermal dissipation.

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

### Absolute Maximum Ratings<sup>(1)(2)(3)</sup>

PVIN, AVIN, SW, EN, FB, SS to GND		-0.3V to 6.0V
ESD Susceptibility <sup>(4)</sup>		±2 kV
Power Dissipation		Internally Limited
Junction Temperature		150°C
Storage Temperature Range		-65°C to +150°C
Lead Temperature	Soldering (10 sec)	260°C
	Vapor Phase (60 sec)	215°C
Infrared		220°C

- (1) Absolute Maximum Ratings are limits beyond which damage to the device may occur. Operating Ratings are conditions under which operation of the device is intended to be functional. For ensured specifications and test conditions, see the Electrical Characteristics.
- (2) PGND and AGND are electrically connected together on the PC board and the resultant net is termed GND.
- (3) If Military/Aerospace specified devices are required, please contact the Texas Instruments Sales Office/ Distributors for availability and specifications.
- (4) The human body model is a 100 pF capacitor discharged through a 1.5 kΩ resistor into each pin. Test method is per JESD22-A114.

### Operating Ratings<sup>(1)(2)</sup>

PVIN to GND	2.95V to 5.5V
AVIN to GND	2.95V to 5.5V
Junction Temperature	-40°C to +125°C

- (1) PGND and AGND are electrically connected together on the PC board and the resultant net is termed GND.
- (2) Absolute Maximum Ratings are limits beyond which damage to the device may occur. Operating Ratings are conditions under which operation of the device is intended to be functional. For ensured specifications and test conditions, see the Electrical Characteristics.

## Electrical Characteristics

Specifications with standard typeface are for  $T_J = 25^\circ\text{C}$  only; limits in bold face type apply over the Operating Junction Temperature Range  $T_J$  range of  $-40^\circ\text{C}$  to  $125^\circ\text{C}$ . Minimum and maximum limits are ensured through test, design, or statistical correlation. Typical values represent the most likely parametric norm at  $T_J = 25^\circ\text{C}$ , and are provided for reference purposes only.  $AVIN = PVIN = EN = 5.0\text{V}$ , unless otherwise indicated in the Conditions column.

Symbol	Parameter	Conditions	Min <sup>(1)</sup>	Typ <sup>(2)</sup>	Max <sup>(1)</sup>	Units
<b>SYSTEM PARAMETERS</b>						
$V_{REF}$	Reference Voltage <sup>(3)</sup>	Measured at the FB pin	<b>0.790</b>	0.8	<b>0.808</b>	V
$\Delta V_{REF}/\Delta AVIN$	Line Regulation <sup>(3)</sup>	$\Delta AVIN = 2.95\text{V}$ to $5.50\text{V}$		0.04	<b>0.6</b>	%
$\Delta V_{REF}/\Delta I_O$	Load Regulation	Normal operation		0.25		mV/A
$V_{ON}$	UVLO Threshold (AVIN)	Rising		2.6	<b>2.95</b>	V
		Falling hysteresis	<b>25</b>	170	<b>375</b>	mV
$R_{DS(ON)-P}$	PFET On Resistance	$I_{SW} = 4\text{A}$		35	<b>65</b>	m $\Omega$
$R_{DS(ON)-N}$	NFET On Resistance	$I_{SW} = 4\text{A}$		34	<b>65</b>	m $\Omega$
$I_{SS}$	Soft-Start Current			2		$\mu\text{A}$
$I_{CL}$	Peak Current Limit Threshold		<b>4.5</b>	6.0	<b>6.7</b>	A
$I_Q$	Operating Current	Non-switching		1.7	<b>3</b>	mA
$I_{SD}$	Shut Down Quiescent Current	$EN = 0\text{V}$		230	<b>500</b>	$\mu\text{A}$
<b>PWM SECTION</b>

## BLOCK DIAGRAM

## APPLICATIONS INFORMATION

### GENERAL

The LM2854 PowerWise synchronous DC-DC buck regulator belongs to the Texas Instruments SIMPLE SWITCHER family of switching regulators. Integration of the power MOSFETs and associated drivers, compensation component network and the PWM controller reduces the number of external components necessary for a complete power supply design, without sacrificing performance.

### Operation Description

#### SWITCHING FREQUENCY

The LM2854 is available in two switching frequency options, 500 kHz and 1 MHz. Generally, a higher switching frequency allows for faster transient response and a reduction in the footprint area and volume of the external power stage components, while a lower switching frequency affords better efficiency. These factors should be considered when selecting the appropriate switching frequency for a given application.

#### ENABLE

The LM2854 features a enable (EN) pin and associated comparator to allow the user to easily sequence the LM2854 from an external voltage rail, or to manually set the input UVLO threshold. The turn-on or rising threshold and hysteresis for this comparator are typically 1.23V and 0.15V respectively. The precise reference for the enable comparator allows the user to ensure that the LM2854 will be disabled when the system demands it to be.

#### SOFT-START

The LM2854 begins to operate when both the AVIN and EN voltages exceed the rising UVLO and enable thresholds, respectively. A controlled soft-start eliminates inrush currents during start-up and allows the user more control and flexibility when sequencing the LM2854 with other power supplies. An external soft-start capacitor is used to control the LM2854 start-up time. During soft-start, the voltage on the feedback pin is connected internally to the non-inverting input of the error amplifier. The soft-start period lasts until the voltage on the soft-start pin exceeds the LM2854 reference voltage of 0.8V. At this point, the reference voltage takes over at the non-inverting amplifier input.

In the event of either AVIN or EN decreasing below the falling UVLO or enable threshold respectively, the voltage on the soft-start pin is collapsed by discharging the soft-start capacitor through a 5 kΩ transistor to ground.

#### TRACKING

The LM2854 can track the output of a master power supply during soft-start by connecting a resistor divider to the SS pin. In this way, the output voltage slew rate of the LM2854 will be controlled by a master supply for loads that require precise sequencing. When the tracking function is used, a small value soft-start capacitor can be connected to the SS pin to alleviate output voltage overshoot when recovering from a current limit fault.

## PRE-BIASED STARTUP CAPABILITY

The LM2854 is in a pre-biased state when the device starts up with an output voltage greater than zero. This often occurs in many multi-rail applications such as when powering an FPGA, ASIC, or DSP. The output can be pre-biased in these applications through parasitic conduction paths from one supply rail to another. Even though the LM2854 is a synchronous converter, it will not pull the output low when a pre-bias condition exists. The LM2854 will not sink current during start up until the soft-start voltage exceeds the voltage on the FB pin. Since the device can not sink current it protects the load from damage that might otherwise occur if current is conducted through the parasitic paths of the load.

## FEEDBACK VOLTAGE ACCURACY

The FB pin is connected to the inverting input of the voltage loop error amplifier and during closed loop operation its reference voltage is 0.8V. The FB voltage is accurate to within -1.25% / +1.0% over temperature. Additionally, the LM2854 contains error nulling circuitry to substantially eliminate the feedback voltage over temperature drift as well as the long term aging effects of the internal amplifiers. In addition, the 1/f noise of the bandgap amplifier and reference are dramatically reduced. The manifestation of this circuit action is that the duty cycle will have two slightly different but distinct operating points, each evident every other switching cycle. The oscilloscope plot shown previously of the SW pin with infinite persistence set shows this behavior. No discernible effect is evident on the output due to LC filter attenuation. For further information, a Texas Instruments white paper is available on this topic.

## POSITIVE CURRENT LIMIT

The LM2854 employs lossless cycle-by-cycle high-side current limit circuitry to limit the peak current through the high-side FET. The peak current limit threshold, denoted  $I_{CL}$ , is nominally set at 6A internally. When a current greater than  $I_{CL}$  is sensed through the PFET, its on-time is immediately terminated and the NFET is activated. The NFET stays on for the entire next four switching cycles (effectively four PFET pulses are skipped). During these skipped pulses, the voltage on the soft-start pin is reduced by discharging the soft-start capacitor by a current sink on the soft-start pin of nominally 6  $\mu$ A or 14  $\mu$ A for the 500 kHz or 1 MHz options, respectively. Subsequent over-current events will drain more and more charge from the soft-start capacitor, effectively decreasing the reference voltage as the output droops due to the pulse skipping. Reactivation of the soft-start circuitry ensures that when the over-current situation is removed, the part will resume normal operation smoothly.

## NEGATIVE CURRENT LIMIT

The LM2854 implements negative current limit detection circuitry to prevent large negative current in the inductor. When the negative current sensed in the low-side NFET is below approximately -0.4A, the present switching cycle is immediately terminated and both FETs are turned off. When both FETs are off, the negative inductor current originally flowing in the low-side NFET and into the SW pin commutates to the high-side PFET's body diode and ramps back to zero. At this point, the SW pin becomes a high impedance node and ringing can be observed on the SW node as the stored energy in the inductor is dissipated while resonating with the parasitic nodal capacitance.

## OVER-TEMPERATURE PROTECTION

When the LM2854 senses a junction temperature greater than 165°C, both switching FETs are turned off and the part enters a sleep state. Upon sensing a junction temperature below 155°C, the part will re-initiate the soft-start sequence and begin switching once again. This feature is provided to prevent catastrophic failure due to excessive thermal dissipation.

## LOOP COMPENSATION

The LM2854 preserves flexibility by integrating the control components around the error amplifier while utilizing three small external compensation components from  $V_{OUT}$  to FB. An integrated type II (two pole, one zero) voltage-mode compensation network is featured. To ensure stability, an external resistor and small value capacitor can be added across the upper feedback resistor as a pole-zero pair to complete a type III (three pole, two zero) compensation network. For correct selection of these components, see the design section of this datasheet.

## Design Guidelines

### INPUT FILTER CAPACITOR

Fast switching currents place a large strain on the input supply to a buck regulator. A capacitor placed close to the PVIN and PGND pins of the LM2854 helps to supply the instantaneous charge required when the regulator demands a pulse of current every switching cycle. In fact, the input capacitor conducts a square-wave current of peak-to-peak amplitude equal to  $I_{OUT}$ . With this high AC current present in the input capacitor, the RMS current rating becomes an important parameter. The necessary RMS current rating of the input capacitor to a buck regulator can be estimated by

$$I_{Cin(RMS)} = I_{OUT} \sqrt{D(1-D)} \quad (1)$$

where the PWM duty cycle,  $D$ , is given by

$$D = \frac{V_{OUT}}{V_{IN}} \quad (2)$$

Neglecting capacitor ESR, the resultant input capacitor AC ripple voltage is a triangular waveform with peak-to-peak amplitude specified as follows

$$\Delta V_{in} = \frac{V_{OUT} D(1-D)}{f_{SW} C_{IN}} \quad (3)$$

The maximum input capacitor ripple voltage and RMS current occur at 50% duty cycle. A 22  $\mu F$  or 47  $\mu F$  high quality dielectric (X5R, X7R) ceramic capacitor with adequate voltage rating is typically sufficient as an input capacitor to the LM2854. The input capacitor should be placed as close as possible to the PVIN and PGND pins to substantially eliminate the parasitic effects of any stray inductance or resistance on the PC board and supply lines. Additional bulk capacitance with higher ESR may be required to damp any resonance effects of the input capacitance and parasitic inductance.

### AVIN FILTERING COMPONENTS

In addition to the large input filter capacitor, a smaller ceramic capacitor such as a 0.1  $\mu F$  or 1.0  $\mu F$  is recommended between AVIN and AGND to filter high frequency noise present on the PVIN rail from the quiet AVIN supply. For additional filtering in noisy environments, a small RC filter can be used on the AVIN pin as shown below.

In general,  $R_F$  is typically selected between 1  $\Omega$  and 10  $\Omega$  so that the steady state voltage drop across the resistor due to the AVIN bias current does not affect the UVLO level. Recommended filter capacitor,  $C_F$ , is 1.0  $\mu F$  in X5R or X7R dielectric.

### SOFT-START CAPACITOR

When the LM2854 is enabled, the output voltage will ramp up linearly in the time dictated by the following relationship

$$t_{SS} = \frac{C_{SS} \times V_{REF}}{I_{SS}} \quad (4)$$

where  $V_{REF}$  is the internal reference voltage (nominally 0.8V),  $I_{SS}$  is the soft-start charging current (nominally 2  $\mu A$ ) and  $C_{SS}$  is the external soft-start capacitance. Rearranging this equation allows for the necessary soft-start capacitor for a given startup time to be calculated as follows

$$C_{SS} = \frac{t_{SS} \times 2 \mu A}{0.8V} \quad (5)$$

Thus, the required soft start capacitor per unit output voltage startup time is given by

$$C_{SS} = 2.5 \text{ nF} / \text{ms} \quad (6)$$

For example, a 10 nF soft-start capacitor will yield a 4 ms soft-start time.

### TRACKING - EQUAL SOFT-START TIME

One way to use the tracking feature is to design the tracking resistor divider so that the master supply output voltage,  $V_{OUT1}$ , and the LM2854 output voltage,  $V_{OUT2}$ , both rise together and reach their target values at the same time. This is termed ratiometric startup. For this case, the equation governing the values of tracking divider resistors  $R_{T1}$  and  $R_{T2}$  is given by

$$R_{T1} = \frac{R_{T2}}{V_{OUT1} - 1.0V} \quad (7)$$

The above equation includes an offset voltage to ensure that the final value of the SS pin voltage exceeds the reference voltage of the LM2854. This offset will cause the LM2854 output voltage to reach regulation slightly before the master supply. A value of 33 kΩ 1% is recommended for  $R_{T2}$  as a compromise between high precision and low quiescent current through the divider while minimizing the effect of the 2 μA soft-start current source.

For example, If the master supply voltage  $V_{OUT1}$  is 3.3V and the LM2854 output voltage was 1.8V, then the value of  $R_{T1}$  needed to give the two supplies identical soft-start times would be 14.3 kΩ. A timing diagram for this example, the equal soft-start time case, is shown below.

### TRACKING - EQUAL SLEW RATES

Alternatively, the tracking feature can be used to have similar output voltage ramp rates. This is referred to as simultaneous startup. In this case, the tracking resistors can be determined based on the following equation

$$R_{T1} = \frac{0.8V}{V_{OUT2} - 0.8V} R_{T2} \quad (8)$$

and to ensure proper overdrive of the SS pin

$$V_{OUT2} < 0.8 V_{OUT1} \quad (9)$$

For the example case of  $V_{OUT1} = 5V$  and  $V_{OUT2} = 2.5V$ , with  $R_{T2}$  set to 33 kΩ as before,  $R_{T1}$  is calculated from the above equation to be 15.5 kΩ. A timing diagram for the case of equal slew rates is shown below.

## ENABLE AND UVLO

Using a resistor divider from V<sub>IN</sub> to EN as shown in the schematic diagram below, the input voltage at which the part begins switching can be increased above the normal input UVLO level according to

$$V_{IN(UVLO)} = 1.23V \frac{R_{EN1} + R_{EN2}}{R_{EN2}} \quad (10)$$

For example, suppose that the required input UVLO level is 3.69V. Choosing R<sub>EN2</sub> = 10 kΩ, then we calculate R<sub>EN1</sub> = 20 kΩ.

Alternatively, the EN pin can be driven from another voltage source to cater for system sequencing requirements commonly found in FPGA and other multi-rail applications. The following schematic shows an LM2854 that is sequenced to start based on the voltage level of a master system rail.

## OUTPUT VOLTAGE SETTING

A divider resistor network from V<sub>OUT</sub> to the FB pin determines the desired output voltage as follows

$$V_{OUT} = 0.8V \frac{R_{FB1} + R_{FB2}}{R_{FB2}} \quad (11)$$

R<sub>FB1</sub> is defined based on the voltage loop requirements and R<sub>FB2</sub> is then selected for the desired output voltage. These resistors are normally selected as 0.5% or 1% tolerance.

## COMPENSATION COMPONENT SELECTION

The power stage transfer function of a voltage mode buck converter has a complex double pole related to the LC output filter and a left half plane zero due to the output capacitor ESR, denoted  $R_{ESR}$ . The locations of these singularities are given respectively by

$$f_{LC} = \frac{1}{2\pi \sqrt{L_O C_O \left( \frac{R_{ESR} + R_L}{R_{DCR} + R_L} \right)}} \approx \frac{1}{2\pi \sqrt{L_O C_O}}$$

$$f_{ESR} = \frac{1}{2\pi R_{ESR} C_O}$$
(12)

where  $C_O$  is the output capacitance value appropriately derated for applied voltage and operating temperature,  $R_L$  is the effective load resistance and  $R_{DCR}$  is the series damping resistance associated with the inductor and power switches.

The conventional compensation strategy employed with voltage mode control is to use two compensator zeros to offset the LC double pole, one compensator pole located to cancel the output capacitor ESR zero and one compensator pole located between one third and one half switching frequency for high frequency noise attenuation.

The LM2854 internal compensation components are designed to locate a pole at the origin and a pole at high frequency as mentioned above. Furthermore, a zero is located at 8.8 kHz or 17.6 kHz for the 500 kHz or 1 MHz options, respectively, to approximately cancel the likely location of one LC filter pole.

The three external compensation components,  $R_{FB1}$ ,  $R_{COMP}$  and  $C_{COMP}$ , are selected to position a zero at or below the LC pole location and a pole to cancel the ESR zero. The voltage loop crossover frequency,  $f_{loop}$ , is usually selected between one tenth to one fifth of the switching frequency

$$0.1f_{SW} \leq f_{loop} \leq 0.2f_{SW}$$
(13)

A simple solution for the required external compensation capacitor,  $C_{COMP}$ , with type III voltage mode control can be expressed as

$$C_{COMP}(pF) = \alpha \frac{L_O(\mu H) C_O(\mu F)}{V_{IN}(V)} f_{loop}(kHz)$$
(14)

where the constant  $\alpha$  is nominally 0.038 or 0.075 for the 500 kHz or 1 MHz options, respectively. This assumes a compensator pole cancels the output capacitor ESR zero. Furthermore, since the modulator gain is proportional to  $V_{IN}$ , the loop crossover frequency increases with  $V_{IN}$ . Thus, it is recommended to design the loop at maximum expected  $V_{IN}$ .

The upper feedback resistor,  $R_{FB1}$ , is selected to provide adequate mid-band gain and to locate a zero at or below the LC pole frequency. The series resistor,  $R_{COMP}$ , is selected to locate a pole at the ESR zero frequency. Thus

$$R_{FB1} = \frac{1}{2\pi C_{COMP} f_{LC}}$$

$$R_{COMP} = \frac{1}{2\pi C_{COMP} f_{ESR}}$$
(15)

Note that the lower feedback resistor,  $R_{FB2}$ , has no impact on the control loop from an AC standpoint since the FB pin is the input to an error amplifier and effectively at AC ground. Hence, the control loop can be designed irrespective of output voltage level. The only caveat here is the necessary derating of the output capacitance with applied voltage. Having chosen  $R_{FB1}$  as above,  $R_{FB2}$  is then selected for the desired output voltage.

Table 1 and Table 2 list inductor and ranges of capacitor values that work well with the LM2854, along with the associated compensation components to ensure stable operation. Values different than those listed may be used, but the compensation components may need to be recalculated to avoid degradation in phase margin. Note that the capacitance ranges specified refer to in-circuit values where the nominal capacitance value is adequately derated for applied voltage.

### FILTER INDUCTOR AND OUTPUT CAPACITOR SELECTION

In a buck regulator, selection of the filter inductor and capacitor will affect many key system parameters, including stability, transient response and efficiency. The LM2854 can accommodate relatively wide ranges of output capacitor and filter inductor values in a typical application and still achieve excellent load current transient performance and low output voltage ripple.

The inductance is chosen such that the peak-to-peak inductor current ripple,  $\Delta i_L$ , is approximately 25 to 40% of  $I_{OUT}$  as follows

$$L_O = \frac{V_{OUT}(1-D)}{\Delta i_L f_{SW}} \cong \frac{V_{OUT}(1-D)}{0.3 I_{OUT} f_{SW}}$$
(16)

Note that the peak inductor current is the DC output current plus half the ripple current and reaches its highest level at lowest duty cycle (or highest  $V_{IN}$ ). It is recommended that the inductor should have a saturation current rating in excess of the current limit level.

When operating the LM2854 at input voltages above 5.2V, the inductor should be sized to keep the minimum inductor current above -0.5A. For most applications this should only occur at light loads or when the inductor is drastically undersized. To ensure the current never goes below -0.5A for any application, the peak-to-peak ripple current ( $\Delta i_L$ ) in the inductor should be less than 1A. Keeping the minimum inductor current above -0.5A limits the energy storage in the inductor and helps prevent the switch node voltage from exceeding the absolute maximum specification when the low side FET turns off.

Table 3 lists examples of off-the-shelf powdered iron and ferrite based inductors that are suitable for use with the LM2854. The output capacitor can be of ceramic or electrolytic chemistry. The chosen output capacitor requires sufficient DC voltage rating and RMS ripple current handling capability.

The output capacitor RMS current and peak-to-peak output ripple are given respectively by

$$I_{Cout(RMS)} = \frac{\Delta i_L}{\sqrt{12}}$$

$$\Delta V_{OUT} = \Delta i_L \sqrt{R_{ESR}^2 + \left( \frac{1}{8f_{SW}C_O} \right)^2}$$
(17)

In general, 22  $\mu$ F to 100  $\mu$ F of ceramic output capacitance is sufficient for both LM2854 frequency options given the optimal high frequency characteristics and low ESR of ceramic dielectric. It is advisable to consult the manufacturer's derating curves for capacitance voltage coefficient as the in-circuit capacitance may drop significantly with applied voltage.

Tantalum or organic polymer electrolytic capacitance may be suitable with the LM2854 500 kHz option, particularly in applications where substantial bulk capacitance per unit volume is required. However, the high loop bandwidth achievable with the LM2854 obviates the necessity for large bulk capacitance during transient loading conditions.

Table 4 lists some examples of commercially available capacitors that can be used with the LM2854.

## PC Board Layout Guidelines

PC board layout is an important part of DC-DC converter design. Poor board layout can disrupt the performance of a DC-DC converter and surrounding circuitry by contributing to EMI, ground bounce and resistive voltage drop in the traces. These can send erroneous signals to the DC-DC converter resulting in poor regulation or instability. Good layout can be implemented by following a few simple design rules.

### 1. Minimize area of switched current loops.

There are two loops where currents are switched at high  $di/dt$  slew rates in a buck regulator. The first loop represents the path taken by AC current flowing during the high side PFET on time. This current flows from the input capacitor to the regulator PVIN pins, through the high side FET to the regulator SW pin, filter inductor, output capacitor and returning via the PCB ground plane to the input capacitor. The second loop represents the path taken by AC current flowing during the low side NFET on time. This current flows from the output capacitor ground to the regulator PGND pins, through the NFET to the inductor and output capacitor. From an EMI reduction standpoint, it is imperative to minimize this loop area during PC board layout by physically locating the input capacitor close to the LM2854. Specifically, it is advantageous to place  $C_{IN}$  as close as possible to the LM2854 PVIN and PGND pins. Grounding for both the input and output capacitor should consist of a localized top side plane that connects to PGND and the exposed die attach pad (DAP). The inductor should be placed close to the SW pin and output capacitor.

### 2. Minimize the copper area of the switch node.

The LM2854 has two SW pins optimally located on one side of the package. In general the SW pins should be connected to the filter inductor on the top PCB layer. The inductor should be placed close to the SW pins to minimize the copper area of the switch node.

### 3. Have a single point ground for all device analog grounds located under the DAP.

The ground connections for the Feedback, Soft-start, Enable and AVIN components should be routed to the AGND pin of the device. The AGND pin should connect to PGND under the DAP. This prevents any switched or load currents from flowing in the analog ground traces. If not properly handled, poor grounding can result in degraded load regulation or erratic switching behavior.

### 4. Minimize trace length to the FB pin.

Since the feedback (FB) node is high impedance, the trace from the output voltage setpoint resistor divider to FB pin should be as short as possible. This is most important as relatively high value resistors are used to set the output voltage. The FB trace should be routed away from the SW pin and inductor to avoid noise pickup from the SW pin. Both feedback resistors,  $R_{FB1}$  and  $R_{FB2}$ , and the compensation components,  $R_{COMP}$  and  $C_{COMP}$ , should be located close to the FB pin.

### 5. Make input and output bus connections as wide as possible.

This reduces any voltage drops on the input or output of the converter and maximizes efficiency. To optimize voltage accuracy at the load, ensure that a separate feedback voltage sense trace is made to the load. Doing so will correct for voltage drops and provide optimum output accuracy.

### 6. Provide adequate device heat-sinking.

Use an array of heat-sinking vias to connect the DAP to the ground plane on the bottom PCB layer. If the PCB has a plurality of copper layers, these thermal vias can also be employed to make connection to inner layer heat-spreading ground planes. For best results use a 5 x 3 via array with minimum via diameter of 10 mils. Ensure enough copper area is used to keep the junction temperature below 125°C.

## LM2854 Application Circuit Schematic and BOMs

This section provides several application solutions with an associated bill of materials. All bill of materials reference the schematic below. The compensation for each solution was optimized to work over the full input range. Many applications have a fixed input voltage rail. It is possible to modify the compensation to obtain a faster transient response for a given input voltage operating point.

**Table 5. LM2854 500kHz Bill of Materials,  $V_{IN} = 5V$ ,  $V_{OUT} = 3.3V$ ,  $I_{OUT(MAX)} = 4A$ , Optimized for Efficiency**

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

<sup>(6)</sup> Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
