Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 15-0  | CRC_CURSEC1 |       | <b>Channel 1 Current Sector ID Register.</b> In AUTO mode, this register contains the current sector number of which the signature verification fails. The sector counter is a free running up counter. When a sector fails, the erroneous sector number is logged into current sector ID register and the CRC fail interrupt is generated. The sector ID register is frozen until it is read and the CRC fail status bit is cleared by CPU. While it is frozen, it does not capture another erroneous sector number. When this condition happens, an overrun interrupt is generated instead. Once the register is read and the CRC fail interrupt flag is cleared it can capture new erroneous sector number. In Semi-CPU mode, this register is used to indicate the sector number for which the compression complete has last happened. |

### 14.4.12 CRC Channel 1 Watchdog Timeout Preload Register A (CRC\_WDTPLD1)

| 15-0  | CRC_CURSEC2 |       | <b>Channel 2 Current Sector ID Register.</b> In AUTO mode, this register contains the current sector number of which the signature verification fails. The sector counter is a free running up counter. When a sector fails, the erroneous sector number is logged into current sector ID register and the CRC fail interrupt is generated. The sector ID register is frozen until it is read and the CRC fail status bit is cleared by CPU. While it is frozen, it does not capture another erroneous sector number. When this condition happens, an overrun interrupt is generated instead. Once the register is read and the CRC fail interrupt flag is cleared it can capture new erroneous sector number. In Semi-CPU mode, this register is used to indicate the sector number for which the compression complete has last happened. |

### 14.4.25 CRC Channel 2 Watchdog Timeout Preload Register A (CRC\_WDTPLD2)

## 15.1 Overview

The vectored interrupt manager (VIM) provides hardware assistance for prioritizing and controlling the many interrupt sources present on a device. Interrupts are caused by events outside of the normal flow of program execution. Normally, these events require a timely response from the central processing unit (CPU); therefore, when an interrupt occurs, the CPU switches execution from the normal program flow to an interrupt service routine (ISR).

The VIM module has the following features:

- Supports 95 interrupt channels, in both register vectored interrupt and hardware vectored interrupt mode.
  - Provides IRQ vector directly to the CPU VIC port
  - Provides FIQ/IRQ vector through registers
  - Provides programmable priority and enable for interrupt request lines
- Provides a direct hardware dispatch mechanism for fastest IRQ dispatch.
- Provides two software dispatch mechanisms for backward compatibility with earlier generation of TI processors.
  - Index interrupt
  - Register vectored interrupt
- Parity protected vector interrupt table against soft errors.

## 15.2 Device Level Interrupt Management

A block diagram of device level interrupt handling is shown in [Figure 15-1](#). When an event occurs within a peripheral, the peripheral makes an interrupt request to the VIM. Then, VIM prioritizes the requests from peripherals and provides the address of the highest interrupt service routine (ISR) to the CPU. Finally, CPU starts executing the ISR instructions from that address in the ISR. [Section 15.2.1](#) through [Section 15.2.3](#) provide additional details about these three steps.

**Figure 15-1. Device Level Interrupt Block Diagram**

### 15.2.1 Interrupt Generation at the Peripheral

Interrupt generation begins when an event occurs within a peripheral module. Some examples of interrupt-capable events are expiration of a counter within a timer module, receipt of a character in a communications module, and completion of a conversion in an analog-to-digital converter (ADC) module. Some device peripherals are capable of requesting interrupts on more than one interrupt request line.

Interrupts are not always generated when an event occurs; the peripheral must make an interrupt request to the VIM based on the event occurrence. Typically, the peripheral contains:

- An interrupt flag bit for each event to signify the event occurrence.
- An interrupt enable bit to control whether the event occurrence causes an interrupt request to the VIM.

### 15.2.2 Interrupt Handling at the CPU

The ARM CPU provides two vectors for interrupt requests—fast interrupt requests (FIQs) and normal interrupt requests (IRQs). FIQs are higher priority than IRQs, and FIQ interrupts may interrupt IRQ interrupts.

---

**NOTE:** The FIQ implemented in Cortex-R4F is Non-Maskable Fast Interrupts (NMFI). Once FIQ is enabled (by clearing F bit in CPSR), it can NOT be disabled by setting F bit in CPSR. Only a reset or an FIQ will be able to set the F bit in CPSR. By hardware, Non Maskable FIQ are not reentrant.

---

After reset (power reset or warm reset), both FIQ and IRQ are disabled. The CPU may enable these interrupt request channels individually within the CPSR (Current Program Status Register); CPSR bits 6 and 7 must be cleared to enable the FIQ (bit 6) and IRQ (bit 7) interrupt requests at the CPU. CPSR is writable in privilege mode only. [Example 15-2](#) shows how to enable the IRQ and FIQ through CPSR.

When the CPU receives an interrupt request, the CPSR mode field changes to either FIQ or IRQ mode. When an IRQ interrupt is received, the CPU disables other IRQ interrupts by setting CPSR bit 7. When an FIQ interrupt is received, the CPU disables both IRQ and FIQ interrupts by setting CPSR bits 6 and 7.

A write of 1 to CPSR bit 7 disables the IRQ from CPU. However, a write of 1 to CPSR bit 6 leaves it unchanged. [Example 15-2](#) also shows how to disable the IRQ through CPSR.

### 15.2.3 Software Interrupt Handling Options

The device supports three different possibilities for software to handle interrupts

1. Index interrupts mode (compatible with TMS470R1x legacy code)

After the interrupt is received by the CPU, the CPU branches to 0x18 (IRQ) or 0x1C (FIQ) to execute the main ISR. The main ISR routine reads the offset register (IRQINDEX, FIQINDEX) to determine the source of the interrupt.

This mode is compatible with the TMS470R1x (CIM) module and provides the same interrupt registers.

This mode could be used if legacy code needs to be reused, porting it from the TMS470R1x family. However, imported software will not benefit from the VIM improvements.

To port legacy software, the interrupt vector at 0x18 (IRQ) or 0x1C (FIQ) only needs to be a branch statement to a software interrupt table. The software interrupt table reads the pending interrupt from a vector offset register (FIQINDEX[7:0] for FIQ interrupts and IRQINDEX[7:0] for IRQ interrupts). All pending interrupts can be viewed in the INTREQ register. [Example 15-4](#) shows how to respond to FIQ with short latency in this mode.

2. Register vectored interrupts (automatically provide vector address to application)

Before enabling interrupts, the application software also has to initiate the interrupt vector table (VIM RAM).

Once the VIM receives an interrupt, it loads the address of ISR from interrupt vector table, and store it into the interrupt vector register (IRQVECREG for IRQ interrupt, FIQVECREG for FIQ interrupt).

After the interrupt is received by the CPU, the CPU executes the instruction placed at 0x18 or 0x1C (IRQ or FIQ vector) to load the address of ISR (interrupt vector) from the interrupt vector register.

[Example 15-3](#) illustrates the configuration for the exception vectors using this mode.

3. Hardware vectored interrupts (automatically dispatch to ISR, IRQ only)

Before enabling interrupts, the application software must initiate the interrupt vector table (VIM RAM) pointing to the ISR for each interrupt channel.

After the interrupt (IRQ) is received by the CPU, CPU reads the address of ISR directly from the interface with VIM (VIC port) instead of branching to 0x18. The CPU will branch directly to the ISR.

The hardware vectored interrupt behavior must be explicitly enabled by setting the vector enable (VE) bit in the CP15 R1 register. This bit resets to 0, so that the default state after reset is backward compatible to earlier ARM CPU. [Example 15-1](#) shows how to enable the hardware vectored interrupt.

---

**NOTE:** This mode is NOT available for FIQ.

---

4. Software-Based Priority Decoding Scheme

If the application uses a software-based interrupt priority decoding scheme instead of the hardware vector capabilities, then there is an additional step which was not required on earlier devices. This version of the VIM will hold an interrupt request generated by a peripheral. When the software clears the interrupt condition in the source module (for example, RTI, GIO, and so on), then it must also perform an additional clear of the interrupt request in the VIM. This can be done by reading the IRQVECREG register [Section 15.8.14](#) or FIQVECREG [Section 15.8.15](#) register, or by writing a '1' to the INTREQ(i) bit [Section 15.8.9](#) in the VIM. This is not necessary if any of the three previous methods are used as the interrupt request bit in the VIM will be automatically cleared when the vector is read.

## 15.3 Interrupt Handling Inside VIM

A block diagram of the interrupt handling inside VIM is shown in [Figure 15-2](#)

**Figure 15-2. VIM Interrupt Handling Block Diagram**

### 15.3.1 VIM Interrupt Channel Mapping

The VIM support 96 interrupt channels (including phantom interrupt). A block diagram of the VIM interrupt requests arrangement from peripheral modules to the interrupt channels, is provided in [Figure 15-3](#). Each interrupt channel(CHANx) has a corresponding mapping register bit field (CHANMAPx[6:0]). This mapping register determines which interrupt channel it maps each VIM interrupt request. With this scheme, the same request can be mapped to multiple channels. A lower numbered channel in each FIQ and IRQ has higher priority. The programmability of the VIM allows software to control the interrupt priority.

**Figure 15-3. VIM Channel Mapping**

**NOTE: CHAN95**

CHAN95 has no dedicated interrupt vector table entry. Therefore, CHAN95 shall NOT be remapped to other INT\_REQ (INT\_REQ95 is reserved at device level).

In the reset state, the VIM maps all of the interrupt requests in the system to their respective interrupt channels. [Figure 15-4](#) shows the default state following the reset.

[Figure 15-5](#) shows the VIM INT2 is remapped to both Channel 2 and 4, and INT3 is mapped to channel 3.

**NOTE:** By mapping INT2 to channel 2 and channel 4, and mapping INT3 to channel 3, it is possible for the software to change the priority dynamically by changing the ENABLE register (REQENASET and REQENACLR). When channel 2 is enabled, the priority is:

1. INT0
2. INT1
3. INT2
4. INT3

Disabling channel 2, the priority becomes:

1. INT0
2. INT1
3. INT3
4. INT2

**Figure 15-4. VIM in Default State**

**NOTE:** CHAN0 and CHAN1 are hardwired to INT\_REQ0 and INT\_REQ1, so they cannot be remapped.

**Figure 15-5. VIM in a Programmed State**

**NOTE:** CHAN0 and CHAN1 are hard wired to INT\_REQ0 and INT\_REQ1, so they cannot be remapped.

### 15.3.2 VIM Input Channel Management

As shown in Figure 15-6, the VIM enables channels on a channel-by-channel basis (in the REQENASET and REQENACLR registers); unused channels may be masked to prevent spurious interrupts.

**NOTE:** The interrupt ENABLE register does not affect the value of INTREQ.

**Figure 15-6. Interrupt Channel Management**

By default, interrupt CHAN0 is mapped to ESM (Error Signal Module) high level interrupt and CHAN1 is reserved for other NMI. For safety reasons, these two channels are mapped to FIQ only and can **NOT** be disabled through ENABLE registers.

**NOTE: NMI Channel**

Channel 0 and channel 1 are not maskable by the REQENASET / REQENACLR bit and both channel are routed exclusively to FIQ/NMI request line (FIRQPR0 and FIRQPR1 have no effect).

The VIM prioritizes the received interrupts based upon a programmed prioritization scheme. The VIM can send two interrupt requests to the CPU simultaneously—one IRQ and one FIQ. If both interrupt types are enabled at the CPU level, then the FIQ has greater priority and is handled first. Each interrupt channel, except channel 0 and 1, can be assigned to send either an FIQ or IRQ request to the CPU (in the FIRQPR register).

The VIM provides a default prioritization scheme, which sends the lowest numbered active channel (in each FIQ and IRQ classes) to the CPU. Within the FIQ and IRQ classes of interrupts, the lowest channel has the highest priority interrupt. The channel number is programmable through register CHANMAPx.

When a read occurs from the CPU or VIM, the VIM calculates the parity from the data coming from the interrupt vector table and compares it to the parity stored in the table. The access of the data and the parity is performed in the same clock cycle.

If the parity bit does not match the calculated parity, a parity error is generated and the VIM stores the address of the error in the ADDERR register. The parity flag error (PARFLG) is set.

---

**NOTE:** The PARFLG register is only for bypassing the interrupt vector table in case of a parity fault. It should be used only to maintain the interrupt vector table bypassed. The checking of the parity fault should be done in the error signalling module (ESM) module where all parity errors are flagged.

---

Since the interrupt vector table may have an error, the FBPARERR register will provide to the VIC port, IRQVECREG and FIQVECREG, a fall-back address to an ISR that can restore the interrupt vector table content. The FBPARERR register should be set before initializing the interrupt in the interrupt vector table, to avoid branching to an unpredictable location.

The normal operation is restored when the PARFLG is cleared by the CPU. It is recommended to restore the content of the VIM before clearing the PARFLG.

The parity error signal is forwarded to the ESM.

### 15.4.2 Enabling and Controlling the VIM Parity

The polarity of VIM parity is controlled by the DEVCR1 register in the system module (address 0xFFFFFDC). The parity enable is controlled by the PARCTL register. After reset, the parity is disabled.

Parity checking can be enabled by writing 0xA (1010b) in the PARENA[3:0] bit field of the PARCTL register. The default polarity is odd. The polarity can be changed to even by writing 5 (0101b) in the DEVPARSEL[3:0] bit field of the DEVCR1 register.

### 15.4.3 Interrupt Vector Table Initialization

After reset, the interrupt vector table content, including the parity bits is not initialized. Therefore, the CPU need to initialize all of the interrupt addresses into the table, before enabling the corresponding interrupt channel. If parity is required, this initialization should be done after the parity functionality is enabled. In this way, the corresponding parity bit will be automatically updated. This initialization is only required when vectored interrupts are used, index interrupt management does not need the table to be initialized.

### 15.4.4 Interrupt Vector Table Parity Testing

To test the parity checking mechanism, the parity RAM allows manual insertion of faults. This option is implemented by the test bit in the PARCTL register. Once the bit is set, the parity bits are mapped to 0xFFFF82400. After that, user can force faults into the parity bits. Finally, the parity error can be triggered by reading interrupt vector table (not parity bit) from VIM or CPU.

The interrupt vector table parity can also be verified by inserting faults into interrupt vector table. Once the VIM parity is disabled in system module, user can modify interrupt vector table without impacting the parity bit. After user re-enable interrupt vector table parity, the parity error can be triggered by reading interrupt vector table from VIM or CPU.

**Figure 15-8. Parity Bit Mapping**

## 15.5 VIM Wakeup Interrupt

The wakeup interrupts are used to come out of low power mode (LPM). Any interrupt requests can be used to wake up the device. After reset, all interrupt requests are set to wake up from LPM. However, the VIM can mask unwanted interrupt lines for wake-up by using the WAKEENASET and WAKEENACLR register. The value in REQENASET / REQENACLR does NOT impact the wakeup interrupt.

As shown in Figure 15-9, the WAKEENASET and WAKEENACLR registers will enable/disable an interrupt for wake-up from lowpower mode. All wake-up interrupts are “ORed” into a single signal WAKE\_INT connected to the Global Clock Module.

Figure 15-9. Detail of the IRQ Input

## 15.6 Capture Event Sources

The VIM can select any of the 96 interrupt request to generate up to two capture events for the real-time interrupt (RTI) module (see [Figure 15-10](#)). The value in REQENASET / REQENACLR does NOT impact the capture event. Two registers ([Section 15.8.16](#)) are available, one for each capture event source.

**Figure 15-10. Capture Event Sources**

## 15.7 Examples

The following sections provide examples about the operation of the VIM.

### 15.7.1 Examples - Configure CPU To Receive Interrupts

[Example 15-1](#) shows how to set the vector enable (VE) bit in the CP15 R1 register to enable the hardware vector interrupt. [Example 15-2](#) shows how to enable/disable the IRQ and FIQ through CPSR. As a convention, the program who calls these subroutines shall preserve register R1 if needed. [Example 15-2](#) can ONLY run in privileged mode. However, in USER mode, the application software can force the program into software interrupt by instruction 'SWI'. Then, in the software interrupt service routine, user can write register SPSR, which is the copy of CPSR in this exception mode.

#### Example 15-1. Enable Hardware Vector Interrupt (IRQ Only)

```
_HW_Vec_Init
    MRC p15 ,#0 ,R1 ,c1 ,c0 ,#0
    ORR R1 ,R1 ,#0x01000000      ; Mask 0-31 bits except bit 24 in Sys
                                ; Ctrl Reg of CORTEX-R4
    MCR p15 ,#0 ,R1 ,c1 ,c0 ,#0 ; Enable bit 24
    MOV PC, LR
```

### Example 15-2. Enable/Disable IRQ/FIQ through CPSR

```

FIQENABLE .equ 0x40
IRQENABLE .equ 0x80
.....
_Enable_Fiq
    MRS R1, CPSR
    BIC R1, R1, #FIQENABLE
    MSR CPSR, R1
    MOV PC, LR
.....
_Disable_Irq
    MRS R1, CPSR
    ORR R1, R1, #IRQENABLE
    MSR CPSR, R1
    MOV PC, LR
.....
_Enable_Irq
    MRS R1, CPSR
    BIC R1, R1, #IRQENABLE
    MSR CPSR, R1
    MOV PC, LR

```

## 15.7.2 Examples - Register Vector Interrupt and Index Interrupt Handling

**Example 15-3** shows the configuration for the exception vectors in Register Vector Interrupt handling. After the interrupt is received by the CPU, the CPU branches to 0x18 (IRQ) or 0x1C (FIQ). The instruction placed here should be *LDR PC, [PC, #-0x1B0]*. The pending ISR address is written into the corresponding vector register (IRQVECREG for IRQ, FIQVECREG for FIQ). The CPU reads the content of the register and branches to the ISR.

### Example 15-3. Exception Vector Configuration for VIM Vector

```

        .sect ".intvecs"
00000000h b _RESET           ; RESET interrupt
00000004h b _UNDEF_INST_INT  ; UNDEFINED INSTRUCTION interrupt
00000008h b _SW_INT         ; SOFTWARE interrupt
0000000Ch b _ABORT_PREF_INT ; ABORT (PREFETCH) interrupt
00000010h b _ABORT_DATA_INT ; ABORT (DATA) interrupt
00000014h b #-8             ; Reserved
00000018h ldr pc, [pc, #-0x1B0] ; IRQ interrupt
0000001Ch ldr pc, [pc, #-0x1B0] ; FIQ interrupt

```

**NOTE:** Program Counter (PC) always pointers two instructions beyond the current executed instruction. In this case, PC equals to '0x18 or 0x1C + 0x08'. The *LDR* instruction load the memory at 'PC - 0x1B0', which is '0x18 or 0x1C + 0x08 - 0x1B0 = 0xFFFFFE70 or 0xFFFFFE74'. These are the address of IRQVECREG and FIQVECREG, which store the pending ISR address.

[Example 15-4](#) shows a fast response to the FIQ interrupt in Index Interrupt and can be applied to a system that has more than one channel assigned as a FIQ. It is built in Index Interrupt compatible with TMS470R1x legacy code.

#### Example 15-4. How to Respond to FIQ With Short Latency

```

        .sect ".intvecs"                ; Interrupt and exception vector sector

        .
        .

```

Another way to improve the FIQ latency is to assign only one channel to the FIQ interrupt and to map the ISR code corresponding to this channel directly starting at 0x1C.

**NOTE:** When the CPU is in vector-enabled mode, [Example 15-3](#) and [Example 15-4](#) are still valid. The difference is that the CPU will not read from the 0x18 location during IRQ interrupt, but will jump directly to the corresponding ISR routine.

## 15.8 Registers

This section details the VIM module registers, summarized in [Table 15-1](#). A detailed description of each register and its bits is also provided.

Each register begins on a word boundary. All registers are 32-bit, 16-bit and 8-bit accessible for read and write. Write is only possible in privilege mode. The start address of the VIM module is FFFF FE00h. The parity related VIM registers are placed at FFFF FDECh~FFFF FDF8h.

**Table 15-1. VIM Control Register Summary**

| Offset                  | Acronym     | Register Description                           | Section                         |

| 8    | TEST     | 0          | This bit maps the parity bits into the Interrupt Vector Table frame to make them accessible by the CPU.<br>Parity bits are not memory mapped.           |
|      |          | 1          | Parity bits are memory mapped.                                                                                                                          |
| 7-4  | Reserved | 0          | Read returns 0. Writes have no effect.                                                                                                                  |
| 3-0  | PARENA   | 5h         | VIM parity enable.<br>The VIM parity is disabled.                                                                                                       |
|      |          | All Others | The VIM parity is enabled.<br><b>Note: To avoid soft error to disable VIM parity checking, it is recommended to write Ah to enable parity checking.</b> |

### 15.8.3 Address Parity Error Register (ADDERR)

The address parity error register gives the address of the first parity error location.

**NOTE:** No computation is needed when reading the complete register to retrieve the address in the Interrupt Vector Table.

This register will never be reset by a power-on reset nor any other reset source.

**Figure 15-13. Address Parity Error Register (ADDERR) [Offset = FFFF FDF4h]**

### 15.8.4 Fall-Back Address Parity Error Register (FBPARERR)

This register provides a fall-back address to the VIM if a parity error has occurred in the Interrupt Vector Table. Figure 15-14 and Table 15-5 describe this register.

**NOTE:** This register will never be reset by a power-on reset nor any other reset source.

**Figure 15-14. Fall-Back Address Parity Error Register (FBPARERR) [Offset = FFFF FDF8h]**

|          |  |  |  |  |  |  |  |  |  |  |    |

**Table 15-5. Fall Back Address Parity Error Register (FBPARERR) Field Descriptions**

| Bit  | Field    | Value        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------|----------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | FBPARERR | 0-FFFF FFFFh | Fall back address parity error. This register is used by the VIM if the Interrupt Vector Table has been corrupted. The contents of the IRQVECREG and FIQVECREG registers will reflect the value programmed in FBPARERR. The value provided to the VIC port will also reflect FBPARERR until the PARFLG register has been cleared.<br><br>This register provides the address of the ISR that will restore the integrity of the Interrupt Vector Table. |

### 15.8.5 VIM Offset Vector Registers

The VIM offset register provides the user with the numerical index value that represents the pending interrupt with the highest precedence. The register IRQINDEX holds the index to the highest priority IRQ interrupt; the register FIQINDEX holds the index to the highest priority FIQ interrupt. The index can be used to locate the interrupt routine in a dispatch table, as shown in [Table 15-6](#).

**Table 15-6. Interrupt Dispatch**

| IRQINDEX / FIQINDEX Register Bit Field | Highest Priority Pending Interrupt Enabled |
|----------------------------------------|--------------------------------------------|
| 0x00                                   | No interrupt                               |
| 0x01                                   | Channel 0                                  |
| :                                      | :                                          |
| 0x59                                   | Channel 94                                 |
| 0x60                                   | Channel 95                                 |

---

**NOTE:** Channel 95 has no dedicated interrupt vector table entry. Therefore, Channel 95 shall NOT be used in application.

---

The VIM offset registers are read only. They are updated continuously by the VIM. When an interrupt is serviced, the offset vectors show the index for the next highest pending interrupt or 0x0 if no interrupt is pending.

### 15.8.6 IRQ Index Offset Vector Register (IRQINDEX)

The IRQ offset register provides the user with the numerical index value that represents the pending IRQ interrupt with the highest priority. [Figure 15-15](#) and [Table 15-7](#) describe this register.

**Figure 15-15. IRQ Index Offset Vector Register (IRQINDEX) [Offset = FFFF FE00h]**

|          |  |  |  |  |   |          |  |  |  |  |    |   |

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 7-0  | IRQINDEX | 0-FFh | <b>IRQ index vector.</b> The least significant bits represent the index of the IRQ pending interrupt with the highest precedence, as shown in <a href="#">Table 15-6</a> . When no interrupts are pending, the least significant byte of IRQINDEX is 0.<br><b>Note:</b> A read of register IRQINDEX or IRQVECREG will cause IRQINDEX / IRQVECREG to reflect the index/ISR address for the next highest-priority pending IRQ interrupt. In case there is no other interrupt pending, the IRQINDEX will read 0x00 and the IRQVECREG register will read the phantom interrupt address. |

### 15.8.7 FIQ Index Offset Vector Registers (FIQINDEX)

The FIQINDEX register provides the user with a numerical index value that represents the pending FIQ interrupt with the highest priority. [Figure 15-16](#) and [Table 15-8](#) describe this register.

**Figure 15-16. FIQ Index Offset Vector Register (FIQINDEX) [Offset = FFFF FE04h]**

| 7-0  | FIQINDEX | 0-FFh | <b>FIQ index offset vector.</b> The least significant bits represent the index of the FIQ pending interrupt with the highest precedence, as shown in <a href="#">Table 15-6</a> . When no interrupts are pending, the least significant byte of FIQINDEX is 0x00.<br><b>Note:</b> A read of register FIQINDEX or FIQVECREG will cause FIQINDEX / FIQVECREG to reflect the index/ISR address for the next highest-priority pending FIQ interrupt. In case there is no other interrupt pending, the FIQINDEX will read 0x00 and the FIQVECREG register will read the phantom interrupt address. |

### 15.8.8 FIQ/IRQ Program Control Registers[0] (FIRQPR[0])

The FIQ/IRQ program control registers (FIRQPR[0]) determine whether a given interrupt request will be either FIQ or IRQ. [Figure 15-17](#), [Figure 15-18](#), [Figure 15-19](#) and [Table 15-9](#) describe these registers.

**NOTE:** Channel 0 and 1 are FIQ only, not impacted by this register.

**Figure 15-17. FIQ/IRQ Program Control Register 0 (FIRQPR0) [offset = FFFF FE10h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Figure 15-18. FIQ/IRQ Program Control Register 1 (FIRQPR1) [offset = FFFF FE14h]**

| 95-2 | FIRQPR[95:2] | 0     | <b>FIQ/IRQ program control bits.</b> These bits determine whether an interrupt request from a peripheral is of type FIQ or IRQ. Bit FIRQPRx[95:2] corresponds to request channel[95:2].<br>Interrupt request is of IRQ type. |
|      |              | 1     | Interrupt request is of FIQ type.                                                                                                                                                                                            |
| 1-0  | Reserved     | 3h    | Read only. Writes have no effect.                                                                                                                                                                                            |

### 15.8.9 Pending Interrupt Read Location Registers[0] (INTREQ[0])

The pending interrupt register gives the pending interrupt requests. The register is updated every vbus clock cycle. [Figure 15-20](#), [Figure 15-21](#), [Figure 15-22](#) and [Table 15-10](#) describe this register.

**Figure 15-20. Pending Interrupt Read Location Register 0 (INTREQ0) [offset = FFFF FE20h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Figure 15-21. Pending Interrupt Read Location 1 (INTREQ1) Register [offset = FFFF FE24h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Figure 15-22. Pending Interrupt Read Location 2 (INTREQ2) Register [offset = FFFF FE28h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-10. Pending Interrupt Read Registers[0] (INTREQ[0]) Field Descriptions**

| Bit  | Field        | Value | Description                                                                                                                                                                                                                                                                  |
|------|--------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 95-0 | INTREQ[95:0] |       | Pending interrupt bits. These bits determine whether an interrupt request is pending for the request channel between 0 and 95. The interrupt ENABLE register does not affect the value of the interrupt pending bit. Bit INTREQx[95:0] corresponds to request channel[95:0]. |
|      |              |       | User and Privilege Mode read:                                                                                                                                                                                                                                                |
|      |              | 0     | No interrupt event has occurred.                                                                                                                                                                                                                                             |
|      |              | 1     | An interrupt is pending.                                                                                                                                                                                                                                                     |
|      |              |       | Privilege Mode write only:                                                                                                                                                                                                                                                   |
|      |              | 0     | Writing 0 has no effect.                                                                                                                                                                                                                                                     |
|      |              | 1     | Clears the "interrupt pending" status flag. This write-clear functionality is intended to allow clearing those interrupts which have been signaled to VIM before enabling the interrupt channel, if they are undesired.                                                      |

### 15.8.10 Interrupt Enable Set Registers[0] (REQENASET[0])

The interrupt register enable selectively enables individual request channels. [Figure 15-23](#), [Figure 15-24](#), [Figure 15-25](#) and [Table 15-11](#) describe these registers.

**NOTE:** Channel 0 and 1 are always enabled, not impacted by this register.

**Figure 15-34. Wake-Up Enable Clear Register 2 (WAKEENACLR2) [offset = FFFF FE68h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-14. Wake-Up Enable Clear Registers[0] (WAKEENACLR[0]) Field Descriptions**

| Bit  | Field            | Value | Description                                                                                                                                                                                                                                                  |
|------|------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 95-0 | WAKEENACLR[95:0] | 0     | Wake-up enable clear bits. This vector determines whether the wake-up interrupt line is enabled. Bit WAKEENACLRx[95:0] corresponds to interrupt request channel[95:0].<br>Read: Wake-up interrupt channel is disabled.<br>Write: A write of 0 has no effect. |
|      |                  | 1     | Read: The wake-up interrupt channel is enabled.<br>Write: The wake-up interrupt channel is disabled.                                                                                                                                                         |

### 15.8.14 IRQ Interrupt Vector Register (IRQVECREG)

The interrupt vector register gives the address of the enabled and active IRQ interrupt. [Figure 15-35](#) and [Table 15-15](#) describe these registers.

**Figure 15-35. IRQ Interrupt Vector Register (IRQVECREG) [Offset = FFFF FE70h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 15-15. IRQ Interrupt Vector Register (IRQVECREG) Field Descriptions**

| Bit  | Field     | Value                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------|-----------|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | IRQVECREG | From <a href="#">Section 15.4</a> | IRQ interrupt vector register. This vector gives the address of the ISR with the highest pending IRQ request. The CPU reads the address and branches to this location.<br><b>Note:</b> A read of register IRQINDEX or IRQVECREG will cause IRQINDEX / IRQVECREG to reflect the index/ISR address for the next highest-priority pending IRQ interrupt. In case there is no other interrupt pending, the IRQINDEX will read 0x00 and the IRQVECREG register will read the phantom interrupt address. |

### 15.8.15 FIQ Interrupt Vector Register (FIQVECREG)

The interrupt vector register gives the address of the enabled and active FIQ interrupt. [Figure 15-36](#) and [Table 15-16](#) describe these registers.

**Figure 15-36. IRQ Interrupt Vector Register (FIQVECREG) [Offset = FFFF FE74h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; X = Unknown

**Table 15-16. FIQ Interrupt Vector Register (FIQVECREG) Field Descriptions**

| Bit  | Field     | Value                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------|-----------|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | FIQVECREG | From <a href="#">Section 15.4</a> | FIQ interrupt vector register. This vector gives the address of the ISR with the highest pending FIQ request. The CPU reads the address and branches to this location.<br><b>Note:</b> A read of register FIQINDEX or FIQVECREG will cause FIQINDEX / FIQVECREG to reflect the index/ISR address for the next highest-priority pending FIQ interrupt. In case there is no other interrupt pending, the FIQINDEX will read 0x00 and the FIQVECREG register will read the phantom interrupt address. |

## 15.8.16 Capture Event Register (CAPEVT)

Figure 15-37 and Table 15-17 describe this register.

**Figure 15-37. Capture Event Register (CAPEVT) [Offset = FFFF FE78h]**

|          |    |            |    |

### 15.8.17 VIM Interrupt Control Register[0:31] (CHANCTRL[0:23])

Twenty four interrupt control registers control the 96 interrupt channels of the VIM. Each register controls four interrupt channels: each of them is indexed from 0 to 95. [Table 15-18](#) shows the organization of all the registers and the reset value of each. Each four fields of the register has been named with a generic index that refers to the detailed register organization. [Figure 15-38](#) and [Table 15-19](#) describe these registers.

**Table 15-18. Interrupt Control Registers Organization**

| Offset Address | Register Mnemonic | Register Field 31:24<br>CHANMAP <sub>x0</sub> | Register Field 23:16<br>CHANMAP <sub>x1</sub> | Register Field 15:8<br>CHANMAP <sub>x2</sub> | Register Field 7:0<br>CHANMAP <sub>x3</sub> | Reset Value |
|----------------|-------------------|-----------------------------------------------|-----------------------------------------------|----------------------------------------------|---------------------------------------------|-------------|
| 0xFFFFFE80     | CHANCTRL0         | CHANMAP0                                      | CHANMAP1                                      | CHANMAP2                                     | CHANMAP3                                    | 0x00010203  |
| 0xFFFFFE84     | CHANCTRL1         | CHANMAP4                                      | CHANMAP5                                      | CHANMAP6                                     | CHANMAP7                                    | 0x04050607  |
| ⋮              | ⋮                 | ⋮                                             | ⋮                                             | ⋮                                            | ⋮                                           | ⋮           |
| 0xFFFFFED8     | CHANCTRL22        | CHANMAP88                                     | CHANMAP89                                     | CHANMAP90                                    | CHANMAP91                                   | 0x58595A5B  |
| 0xFFFFFEDC     | CHANCTRL23        | CHANMAP92                                     | CHANMAP93                                     | CHANMAP94                                    | CHANMAP95                                   | 0x5C5D5E5F  |

**NOTE:** CHANMAP0 and CHANMAP1 are not programmable. CHAN0 and CHAN1 are hard wired to INT\_REQ0 and INT\_REQ1.

Do NOT write any value other than 0x5F to CHANMAP95. Channel 95 is reserved because no interrupt vector table entry supports this channel.

## ***Direct Memory Access Controller (DMA) Module***

---

---

This chapter describes the direct memory access (DMA) controller.

| <b>Topic</b>                                            | <b>Page</b> |

| <b>16.1 Overview .....</b>                              | <b>551</b>  |
| <b>16.2 Module Operation .....</b>                      | <b>552</b>  |
| <b>16.3 Control Registers and Control Packets .....</b> | <b>569</b>  |

## 16.1 Overview

The DMA controller is used to transfer data between two locations in the memory map in the background of CPU operations. Typically, the DMA is used to:

- Transfer blocks of data between external and internal data memories
- Restructure portions of internal data memory
- Continually service a peripheral
- Page program sections to internal program memory

### 16.1.1 Main Features

- CPU independent data transfer
- One master port - PortB (64 bits wide) that interfaces microcontrollers Memory System.
- FIFO buffer (4 entries deep and each 64bit wide)
- Channel control information is stored in RAM protected by parity
- 16 channels with individual enable
- Channel chaining capability
- 32 peripheral DMA requests
- Hardware and Software DMA requests
- 8, 16, 32 or 64-bit transactions supported
- Multiple addressing modes for source/destination (fixed, increment, offset)
- Auto-initiation
- Power-management mode
- Memory Protection for the address range DMA can access with four configurable memory regions

#### 16.1.1.1 Block Diagram

Figure 16-1 gives a detailed view of the DMA internal architecture. DMA data read and write access happens through Port B. FIFO B is 4 levels deep and 64-bits wide. 32 DMA requests go into the DMA that can trigger DMA transfers. Five interrupt request lines go out of the DMA to signal that a certain transfer status is reached. Register banks hold the memory mapped DMA configuration registers. Local RAM consists of DMA control packets and is secured by parity. All the programming / configuration of the DMA controller is done via the Peripheral bus.

**Figure 16-1. DMA Block Diagram**

## 16.2 Module Operation

The DMA acts as an independent master in the platform architecture. All DMA memory and register accesses are performed in user mode. If the DMA writes to registers which are only accessible in privileged mode, the write will not be performed.

The DMA registers and its local RAM can only be accessed in privilege mode. Therefore, it is not possible for the DMA to reprogram itself.

### 16.2.1 Memory Space

The DMA controller makes no distinction between program memory and data memory. The DMA controller can transfer to and from any space within the 4 Gbyte physical address map, by programming the absolute address for the source and destination in the control packet.

### 16.2.2 DMA Data Access

The DMA controller refers to data in three levels of granularity:

- **Element:** Depending on the programmed data type, an 8-bit, 16-bit, 32-bit, or a 64-bit value. The type can be individually selected for the source (read) and destination (write). See [Figure 16-2](#) and [Figure 16-3](#) for an example of the use of elements. An element transfer cannot be interrupted.
- **Frame:** One or more elements to be transferred as a unit. A frame transfer can be interrupted between element transfers. See [Figure 16-2](#) for an example.
- **Block:** One or more frames to be transferred as a unit. Each channel can transfer one block of data (once or multiple times). See [Figure 16-3](#) for an example.

**Figure 16-2. Example of a DMA Transfer Using Frame Trigger Source**

**Figure 16-3. Example of a DMA Transfer Using Block Trigger Source**

### 16.2.3 Addressing Modes

There are three addressing modes supported by the DMA controller that can be setup independent for the source and the destination address:

- Constant -- source and/or destination addresses do not change.
- Post incremented -- source and/or destination address are post-incremented by the element size.
- Indexed -- source and/or destination address is post-incremented as defined in the Element Index Offset Register ([Section 16.3.2.5](#)) and the Frame Index Offset Register ([Section 16.3.2.6](#)).

An unaligned address with respect to the element size is not supported. An address chosen during transfer must be divisible by the element size.

## 16.2.4 DMA Channel Control Packets

There are a total of 16 control packets. Each control packet is associated with a channel in a fixed order. For example, control packet 0 stores channel information for channel 0. The DMA requests can be mapped to the individual channels as described in [Section 16.2.7](#). [Figure 16-4](#) illustrates the mapping scheme between DMA requests and channels. Each control packet contains nine fields. The first six fields compose the primary control packet and are programmable during DMA setup. The last three fields compose working control packet and are only readable by the CPU. The working control packets are used to support auto-initiation. The organization of control packets is shown in [Figure 16-5](#).

The primary control packet contains channel information such as source address, destination address, transfer count, element/frame index pointer and channel configuration. Source address, destination address and transfer count also have their respective working images. The three fields of working images compose a working control packet and are not accessible to the CPU in write access.

The first time a DMA channel is selected for a transaction, the following process occurs:

1. The primary control packet is first read by the DMA state machine.
2. Once the channel is arbitrated, the current source address, destination address and transfer count are then copied to their respective working images.
3. When the channel is serviced again by the DMA, the state machine will read both the primary control packet and the working control packet to continue the DMA transaction until the end of an entire block transfer.

When the same channel is requested again, the state machine will start again by reading only the primary control packet and then continue the same process described above. The user software need not set up control packets again because the contents of the primary control packet were never lost. The working images of the control packets are reducing the software overhead and interaction with the DMA module to a minimum.

**NOTE:** Changing the contents of a channel control packet will clear the corresponding pending bit ([Section 16.3.1.2](#)) if the channel has a pending status. If the control packet of an active channel (as indicated in [Section 16.3.1.3](#)) is changed, then the channel will stop immediately at an arbitration boundary. When the same channel is triggered again, it will begin with the new control packet information.

**Figure 16-4. DMA Request Mapping and Control Packet Organization**

**Figure 16-5. Control Packet Organization and Memory Map**

#### 16.2.4.1 Initial Source Address

This field stores the absolute 32-bit source address of the DMA transfer.

#### 16.2.4.2 Initial Destination Address

This field stores the absolute 32-bit destination address of the DMA transfer.

#### 16.2.4.3 Initial Transfer Count

The transfer count field is composed of two parts. The frame transfer count value and the element transfer count value. Each count value is 13 bits wide. As a Single Block transfer maximum of 512 Mbytes of data can be transferred. Element count and frame count are programmed according to the source data structure.

The total transfer size is calculated as stated below:

$$T_{sz} = E_{rsz} \cdot E_{tc} \cdot F_{tc} \quad (27)$$

where

$T_{sz}$  = Total Transfer Size

$E_{rsz}$  = Read Element Size

$E_{tc}$  = Element Transfer Count

$F_{tc}$  = Frame Transfer Count

**NOTE:** A zero element count with a non-zero frame count or a non-zero element count with a zero frame count are all considered as zero total transfer count. No DMA transaction is initiated with any of the counters set to 0.

#### 16.2.4.4 Channel Configuration Word

The channel configuration defines the following individual parameters

- Read element size
- Write element size
- Trigger type (frame or block)
- Addressing mode for source
- Addressing mode for destination
- Auto-initiation mode
- Next control packet to be triggered at control packet finish (Channel Chaining)

#### 16.2.4.5 Element/Frame Index Pointer

There are 4 index pointers that allow the creation of different types of buffers in RAM and address registers in a structured manner: an element index pointer for source and destination and a frame index pointer for source and destination.

The element index pointer for source and/or destination defines the offset to be added after each element transfer to the source and/or destination address. The frame index pointer for source and/or destination defines the offset to be added to the source and/or destination address after the element count reaches zero. The element and frame index pointers must be defined in terms of the number of bytes of offset. The DMA controller does not adjust the element/frame index number according to the element size. An index of 2 means *increment the address by 2* and not by 16 when the element size is 64 bits.

#### 16.2.4.6 Current Source Address

The current source address field contains the current working source address during a DMA transaction. The current source address is incremented during post increment addressing mode or indexing mode.

#### 16.2.4.7 Current Destination Address

The current destination address field contains the current working destination address during a DMA transaction. The current destination address is incremented during post-increment addressing mode or indexing mode.

#### 16.2.4.8 Current Transfer Count

The current transfer count stores the remaining number of elements to be transferred in a block. It is decremented by one for each element read from the source location.

[Figure 16-6](#), [Figure 16-7](#) and [Figure 16-8](#) show some examples of DMA transfers.

**Figure 16-6. DMA Transfer Example 1**

The example assumes the following setup.

Read Element Size = 8 bit

Write Element Size = 8 bit

Element Count = 2

Frame Count = 4

**Figure 16-7. DMA Indexing Example 1**

|      | f1 | f2 | f3  | f4  |
|------|----|----|-----|-----|
| 0x0  | E1 | E5 | E9  | E13 |
| 0x10 | E2 | E6 | E10 | E14 |
| 0x20 | E3 | E7 | E11 | E15 |
| 0x30 | E4 | E8 | E12 | E16 |

Element Index = 16

Frame Index = 4

This example can be applied to either source or destination indexing and assumes the following setup.

Element Size = 16 bit

Element Count = 4

Frame Count = 4

**Figure 16-8. DMA Indexing Example 2**

|      |    |    |    |     |     |     |     |     |
|------|----|----|----|-----|-----|-----|-----|-----|
| 0x0  | E1 | E4 | E7 | E10 | E13 | E16 | E19 | E22 |
| 0x20 |    |    |    |     |     |     |     |     |
| 0x40 | E2 | E5 | E8 | E11 | E14 | E17 | E20 | E23 |
| 0x60 |    |    |    |     |     |     |     |     |
| 0x80 | E3 | E6 | E9 | E12 | E15 | E18 | E21 | E23 |

Element Index = 64

Frame Index = 4

This example can be applied to either source or destination indexing and assumes the following setup.

Element Size = 32 bit

Element Count = 3

Frame Count = 8

### 16.2.5 Priority Queue

User can assign channels in to priority queues to facilitate request handling during arbitration. The port has two priority queues: a high and a low priority queue. The queue can be configured to follow a fixed or rotating priority scheme. Fixed priority is such that the lower the channel number (Figure 16-9), the higher its priority. Rotating priority is based on a round-robin scheme. Initially, the priority list is sorted according to the fixed priority scheme. Channels assigned to the high priority queue are always serviced first according to the selected priority scheme before channels in the low priority queue are serviced. Table 16-1 describes how arbitration is performed according to different priority schemes.

**NOTE:** Since the DMA controller provides the capability to map any one of the 32 hardware DMA request lines to any channel, the numerical order of the hardware DMA request does not imply any priority. The priority of each hardware DMA request is programmed and determined by software.

**Figure 16-9. Fixed Priority Scheme**

The above figure illustrates that by default Lower the channel number, higher the Priority.

**Table 16-1. Arbitration According to Priority Queues and Priority Schemes**

| Queue         | Priority Scheme | Remark                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| High priority | Fixed           | Channels are serviced in an ascending order according to the channel number. The lower the channel number, the higher the priority. A channel will be arbitrated out whenever there is a higher pending channel. Otherwise a channel is completely serviced until its transfer count reaches zero before the next highest pending channel is serviced. When there is no pending channels left in high queue then the DMA switches to service low queue channels.                                                                                           |
|               | Rotating        | Channels are arbitrated by using the round-robin scheme. Arbitration is performed when the FIFO is empty. When there are no pending channels left in high queue then the DMA switches to service low queue channels.                                                                                                                                                                                                                                                                                                                                       |
| Low priority  | Fixed           | Channels are serviced in an ascending order according to the channel number. The lower the channel number the higher the priority. A channel will be arbitrated out whenever there is a higher-priority pending channel. Otherwise a channel is completely serviced until its transfer count reaches zero, before the next highest pending channel is serviced. If there is a pending channel in the high-priority queue while DMA is servicing a low queue channel then DMA will switch back to service high queue channel after an arbitration boundary. |
|               | Rotating        | Channels are arbitrated by using round-robin scheme. Arbitration is performed when the FIFO is empty.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

A Simple Priority Queues example in both Fixed and Rotation Scheme is shown in [Figure 16-10](#).

**Figure 16-10. Example of Priority Queues**

For optimal system performance, the high priority channels should be put in fixed arbitration scheme and low priority channels in the rotating priority scheme as illustrated in [Figure 16-11](#).

**Figure 16-11. Example Channel Assignments**

<sup>1</sup> The above figure illustrates the channel assignments in a system with 16 channels. This approach can be scaled dependent on the total channels available.

### 16.2.6 Data Packing and Unpacking

The DMA controller automatically performs the necessary data packing and unpacking when the read element size differs from the write element size. Data packing is required when the read element size is smaller than the write element size; data unpacking is required when the read element size is larger than the write element size. When the read element size is equal to the write element size, no packing is performed during read, nor is any unpacking performed during write.

Figure 16-12 shows an example of data unpacking in which the DMA is used to transfer 128 transmit data elements to the MibSPI FIFO buffer. In this example, data unpacking is required because the read element size is 64 while the write element size is 16. The DMA first performs a 64-bit read from the source into its FIFO buffer. After the 64-bit data is read into the DMA FIFO buffer, it must unpack the data into four 16-bit data elements before writing out to the destination. Therefore the DMA would need to perform four 16 bit write operations to the destination.

---

**NOTE:** In the example in Figure 16-12, to transmit data at the lower bits of the MibSPI, bits 15:0, the destination address should be incremented by a factor of 2.

---

---

**NOTE:** 1) The element Count (Section 16.3.2.3) refers only to the read element.

2) Data unpacking does not require the DMA request. Once the DMA request is received, data from Source is moved in to FIFO and unpacking happens until the FIFO is empty.

3) DMA assumes the destination is always ready and will perform write immediately. In case of data unpacking and Constant Addressing Mode write (Section 16.3.2.4 (1 - 0) = 0) the destination data will be overwritten by next data or next data might be skipped in case the destination has overflow protection (eg., SCITD register). User should configure DMA to avoid data unpacking if the Destination is configured as Constant Addressing Mode write to avoid data loss.

---

**Figure 16-12. Example of DMA Data Unpacking**

In this example, initialization of the MIBSPI FIFO is illustrated and assumes the following setup:

Read Element Size = 64 bit  
Write Element Size = 16 bit  
Element Count = 32  
Frame Count = 1  
Source Element Index = n/a, use post increment addressing mode  
Source Frame Index = n/a, use post increment addressing mode  
Destination Element Index = 4  
Destination Frame Index = 0

When the read element size is smaller than the write element size, the DMA controller needs to perform data packing. The number of elements to pack is equal to the ratio between the write element size and read element size. In the example in [Figure 16-13](#), the read element size is 16 bits and the write element size is 64 bits. The DMA controller would first pack the first four elements by performing four consecutive 16-bit read accesses of E0, E1, E2, and E3 into the first word of the DMA's internal FIFO. The DMA controller would then perform one single 64-bit write operation to transfer the data to the 64-bit destination memory.

Normally, the DMA controller carries out bus transactions on the bus according to the element size. For example, the DMA controller would perform a 16-bit read transaction if the read element size is programmed as 16 bits, or an 8-bit write transaction if the write element size is programmed as 8 bit. The exception is when the total transfer size as defined in [Equation 27](#) is not a multiple of the write element size.

**Figure 16-13. Example of DMA Data Packing**

In this example, a read of the MIBSPI FIFO is illustrated and assumes the following setup:

Read Element Size = 16 bit  
Write Element Size = 64 bit  
Element Count = 128  
Frame Count = 1  
Source Element Index = 4  
Source Frame Index = 0  
Destination Element Index = n/a, use post increment addressing mode  
Destination Frame Index = n/a, use post increment addressing mode

For example, if the read element size is 8 bits, the element transfer count is equal to 9, and the write element size is 64 bit. The DMA controller would first perform eight 8-bit read transactions from the source. It would then perform a 64-bit write to the destination. When the same channel wins arbitration again, the DMA controller would first perform one 8-bit read from the source, followed by one 8-bit write to the destination, even though the write element size is 64 bit.

**NOTE:** Since peripherals are slower, it is advised to use data packing feature with caution for reading data from peripherals. Improper use might delay servicing other pending DMA channels.

### 16.2.7 DMA Request

There are three ways to start a DMA transfer:

- **Software request:** The transfer will be triggered by writing to SW Channel Enable Set and Status Register (Section 16.3.1.6). The software request can trigger either a block or a frame transfer depending on what the trigger type (TTYPER) bit is set to in the Channel Control Register (Section 16.3.2.4) register.
- **Hardware request:** The DMA controller can handle up to 32 DMA Request lines. A hardware request can trigger either a frame or a block transfer dependent on the setting of TTYPER control bit of the Channel Control Register (Section 16.3.2.4) register.

- **Triggered by other control packet:** When a control packet finishes the programmed number of transfers it can trigger another channel to initiate its transfers.

Each time a DMA request is made, either one frame transfer or one block transfer can be chosen. An active DMA request signal will trigger a DMA transaction.

The DMA controller has a two-level buffer to capture HW requests per channel. When a HW request is generated and the channel is enabled, the corresponding bit in the DMA Status Register (Section 16.3.1.3) is set. The pending register acts as a first-level buffer. Typically, a peripheral acting as a source of a transfer would initiate another request after its data registers have been read out by DMA, even though that data has not been completely transferred to the destination. If a second HW request is generated by the peripheral, the DMA controller has an extra request buffer to capture this second request and service it after the first request is complete.

---

**NOTE:** The DMA cannot capture more than three requests if its request buffers are already full. If any request occur during this moment DMA will discard it.

---

The DMA controller also supports a mix of hardware and software requests on the same channel. Note that such interchangeable usage may result into an out of sync for DMA channel and peripheral. The application needs to be careful as the DMA does not have a built-in mechanism to protect against this loss of synchronization.

If a software request is generated, the corresponding bit in the Channel Pending Register (Section 16.3.1.2) is set accordingly. If the pending request is not completely serviced by the DMA and a hardware request is generated by a peripheral onto the same channel, the DMA will capture and recognize this hardware request into its request buffer.

---

**NOTE:** The DMA controller cannot recognize two software requests on the same channel if the first software request is still pending. If such request occur DMA will discard it. Therefore the user S/W should check the pending register before issue a new software request.

---

### 16.2.8 Auto-Initiation

When Auto-initiation Mode (AIM) bit of Channel Control Register (Section 16.3.2.4) register is enabled for a channel and the channel is triggered by a software request for a block transfer, the channel will restart again using the same channel information stored at the respective control packet after one block transfer is completed. In the case of Hardware Request the channel needs to be retriggered each time after a block is complete even if auto-initiation is enabled.

### 16.2.9 Interrupts

Each channel can be configured to generate interrupts on several transfer conditions:

- Frame transfer complete (FTC) interrupt: an interrupt is issued after the last element of a frame has been transferred.
- Last frame transfer started (LFS) interrupt: an interrupt is issued before the first element of the last frame of a block transfer has started.
- First half of block complete (HBC) interrupt: an interrupt is issued if more than half of the block is transferred.
  - If the number of frames  $n$  is odd, then the HBC interrupt is generated at the end of the frame when  $(n+1) / 2$  number of frames are left in the block.
  - If the number of frames  $n$  is even, then the HBC interrupt is generated at the end of the frame after  $n/2$  number of frames are left in the block.
- Block transfer complete (BTC) interrupt: an interrupt is issued after the last element of the last frame has been transferred.
- Bus error (BER) interrupt: an interrupt is issued when DMA detects an error on the bus. The BER interrupt is connected to the ESM module.
- Memory Protection Unit error (MPU): an interrupt is issued when the DMA detects that the access falls

outside of a memory region programmed in the MPU registers of the DMA. The MPU interrupt is connected to the ESM module.

- Parity error (PAR): an interrupt is issued when the DMA detects a parity error when reading one of the control packets. The PAR interrupt is connected to the ESM module.

The DMA outputs 5 interrupt lines for control packet handling, a parity interrupt and a memory protection interrupt (Figure 16-14). Each type of transfer interrupt condition is grouped together. For example, all block-transfer complete interrupts that are routed to a port are combined (OR'ed). The channel that caused the interrupt is given in the corresponding interrupt channel offset register. Priority between interrupts among the same interrupt type is resolved by a fixed priority scheme. Priority between different interrupt types is resolved in the Vector Interrupt Manager. Figure 16-15 explains the Frame Transfer Complete Interrupt structure in detail.

**NOTE:** Each Channel Specific interrupts in DMA module are routed towards Group A or B to support two different CPUs individually. For devices with Single CPU or Dual CPU where both CPUs are running same code in delayed lock-step as safety feature:

Group A - Interrupts (FTCA, LFS, HBC, BTC and BER) are routed to the ARM CPU.

Group B - Interrupts (FTCA, LFS, HBC, BTC and BER) are not routed out.

User software should configure only Group A interrupts.

**Figure 16-14. DMA Interrupts**

**Figure 16-15. Detailed Interrupt Structure (Frame Transfer Complete Path)**

1 This figure is applicable for HBC, LFS, BTC, and BER interrupt

### 16.2.10 Debugging

The DMA supports four different behaviors in suspend mode. These behaviors can be configured by the user as per the application requirement.

- Immediate stop at a DMA channel arbitration boundary. Please refer to [Table 16-2](#) and [Table 16-3](#) for arbitration boundary definition.
- Finish current frame transfer and continue after suspend ends.
- Finish current block transfer and continue after suspend ends.
- Ignore the suspend. The DMA continues to be operational as in functional mode when debug mode is active.

When the DMA controller enters suspend mode, it continues to sample incoming hardware DMA requests, but the Channel Pending Register ([Section 16.3.1.2](#)) is frozen from being updated. After the suspend ends, all new requests that were received during suspend mode are reflected in the Channel Pending Register ([Section 16.3.1.2](#)).

Except when the DMA controller is configured to ignore suspend mode, no channel arbitration is performed during suspend mode. The current channel under which suspend mode was entered will finish its entire frame or block-transfer after suspend mode ends, depending how the debug option was chosen.

To facilitate debugging, a Watch Point Register ([Section 16.3.1.50](#)) and a Watch Mask Register ([Section 16.3.1.51](#)) are used. The watch point register together with the watch mask register can be configured to watch for a unique address or a range of addresses. When the condition to watch is true, the DMA freezes its state and generates a debug request signal to the host CPU so the state of the DMA can be examined.

### 16.2.11 Power Management

The DMA offers two power-management modes: run and sleep. In run mode, the DMA is fully operational.

The sleep mode shuts down the DMA if no pending channels are waiting to be serviced. If a DMA request is received or a software request is generated by the user software, then the DMA wakes up immediately.

The sleep mode may be used to optimize the DMA module power consumption.

When the system module issues a global low power mode request, the DMA will respond to the system module with an acknowledge if no DMA requests are pending.

**NOTE:** When the DMA is in global low power mode, the clock is stopped and therefore it cannot detect any DMA request. The device must be woken up before a peripheral can generate a DMA request.

### 16.2.12 FIFO Buffer

DMA FIFO is 4 levels deep and 64-bit wide (can hold upto 4 x 64-bits of data). They are used for Data packing and unpacking.

The DMA FIFO has two states:

- **EMPTY** : The FIFO contains no data.
- **FULL** : The FIFO is filled or the element count has reached zero; the read operation has to be stopped.

DMA channels can only be switched when the FIFO is empty. This also implies that arbitration between channels is done when the FIFO is empty.

The FIFO buffer may be bypassed through the use of the bypass feature in the port control register; see Port Control Register ([Section 16.3.1.47](#)) for register details. Writing 1 to this bit limits the FIFO depth to the size of one element. That means after one element is read the write out to the destination will start. This feature is particularly useful to minimize switching latency in-between channels. When bypass mode is enabled, the DMA will perform minimal bus cycles on AHB bus. In addition, the bypass feature allows arbitration between channels that can be carried out at a source element granularity.

However, it has to be considered that while in bypass mode, the DMA controller does not make optimal use of the bus bandwidth. Since the read and write element sizes can be different, then the number of read and write transactions will be different. [Table 16-2](#) and [Table 16-3](#) show a comparison between the number of read and write transactions performed by the DMA controller from one channel to another before arbitration in non-bypass and bypass mode.

**Table 16-2. Maximum Number of DMA Transactions per Channel in Non-Bypass Mode**

|                   | Write Element Size | 8 bit  |         | 16 bit |         | 32 bit |         | 64 bit |         |
|-------------------|--------------------|--------|---------|--------|---------|--------|---------|--------|---------|
| Read Element Size | 8 bit              | 4 read | 4 write | 4 read | 2 write | 4 read | 1 write | 8 read | 1 write |
|                   | 16 bit             | 2 read | 4 write | 4 read | 4 write | 4 read | 2 write | 4 read | 1 write |
|                   | 32 bit             | 1 read | 4 write | 2 read | 4 write | 4 read | 4 write | 4 read | 2 write |
|                   | 64 bit             | 1 read | 8 write | 1 read | 4 write | 2 read | 4 write | 4 read | 4 write |

**Table 16-3. Maximum Number of DMA Transactions per Channel in Bypass Mode**

|                   | Write Element Size | 8 bit  |         | 16 bit |         | 32 bit |         | 64 bit |         |
|-------------------|--------------------|--------|---------|--------|---------|--------|---------|--------|---------|
| Read Element Size | 8 bit              | 1 read | 1 write | 2 read | 1 write | 4 read | 1 write | 8 read | 1 write |
|                   | 16 bit             | 1 read | 2 write | 1 read | 1 write | 2 read | 1 write | 4 read | 1 write |
|                   | 32 bit             | 1 read | 4 write | 1 read | 2 write | 1 read | 1 write | 2 read | 1 write |
|                   | 64 bit             | 1 read | 8 write | 1 read | 4 write | 1 read | 2 write | 1 read | 1 write |

### 16.2.13 Channel Chaining

Channel chaining is used to trigger a single or multiple channels with out an external DMA request. This is possible by chaining one control packet to other. Chain[5:0] field of the Channel Control Register ([Section 16.3.2.4](#)) is used to program the chaining control packet. Chained control packets follow arbitration rules within the pending register. For example if CH1, CH2, CH4, CH5 are triggered together and CH3 is chained with CH1. The order of channels serviced in spite of chaining will be CH1 -> CH2 -> CH3 -> CH4 -> CH5.

In order to setup up channel chain feature, the Channel Control Register (Section 16.3.2.4) register needs to be enabled for all chained channels before triggering first DMA request.

Figure 16-16 illustrates how internally chained request is generated after completing the required transfers and stored in pending register. In this example CH1 is Chained to CH0. When CH0 is triggered CH1 is captured as pending in the Channel Pending Register (Section 16.3.1.2) even when it is not triggered.

**Figure 16-16. Example of Channel Chaining**

## 16.2.14 Memory Protection

The DMA controller is capable of access to the full address range of the device. The protection mechanism allows the protection of up to four memory regions to restrict accesses to those address ranges. This will allow the application to protect critical application data from unintentionally being accessed by the DMA controller.

### 16.2.14.1 Protection Mechanism

The memory protection mechanism consists of the access privilege for a given memory region, the start and end address for the region, and notification of an access violation for the protected region.

Each region to be protected is configured by software by writing the start address and end address for each region into the DMA Memory Protection Registers, DMAMPRxS and DMAMPRxE. The definition of these registers can be found starting at Section 16.3.1.57. Any region in the valid address space can be protected from inappropriate accesses.

The access privileges can be set to one of four permission settings as shown below:

- Full access
- Read only access
- Write only access
- No access

The permissions for a given region are selected by writing the appropriate values in the DMA Memory Protection Control Register (Section 16.3.1.57).

**NOTE:** If the regions defined by the start and end addresses overlap, the region defined first in the register space determines the access privilege. For example, if region 0 and region 1 overlap, the access permissions defined for region 0 will take precedence since region 0 registers are before region 1.

In a case where a memory protection violation occurs, a flag will be set and an interrupt will be generated, if interrupts are enabled. The DMA Memory Protection Status Register (Section 16.3.1.58) contains the status flags for the memory protection mechanism, and the DMA Memory Protection Control Register (Section 16.3.1.57) contains the interrupt enable bits. Upon detection of the memory protection violation, the DMA Channel that caused the violation will be stopped and the next available DMA channel will be serviced.

Figure 16-17 illustrates a protection mechanism.

**Figure 16-17. Example of Protection Mechanism**

### 16.2.15 Parity Checking

Parity checking is implemented using parity on a per-byte basis for DMA Control Packets in the RAM. Checking for even or odd parity can be programmed by a 4-bit key located in the system module that controls the parity configuration on a global basis. This ensures that all modules using parity are acting in the same manner. The default setup after reset is odd parity.

In addition, parity checking can be enabled and disabled within the module by a 4-bit key. The key is located in the Parity Control Register (Section 16.3.1.55).

During a read access, regardless if it was read by the DMA state machine or another master (CPU), the parity is calculated based on the data read from the RAM and compared with the good parity value stored in the parity bits. If any word fails the parity check, then a parity error interrupt is generated. The address that generated the error is detected and is captured for host system debugging in the DMA Parity Error Address Register (Section 16.3.1.56). The address is frozen from being updated until it is read by the bus master.

Additional error handling is dependent on the requestor.

- DMA reading from a control packet RAM: The transmission requested by DMA request will not take place.
- CPU reading from the control packet RAM: The data will be retrieved by the CPU and a parity error

interrupt will be generated.

In both cases, the control packet will be left active or the DMA will be switched off dependent on the ERRA bit in the Parity Control Register ([Section 16.3.1.55](#)).

### 16.2.16 Parity Testing

The parity RAM is accessible to allow manually inserting faults so that the parity checking feature can be tested. Test mode is entered by asserting the TEST bit within the [Section 16.3.1.55](#) register. Once the bit is set, the parity bits are mapped to the control packet RAM starting address A00h.

**NOTE:** When in test mode, no parity checking will be done when reading from parity memory, but parity checking will be performed on the normal memory.

Each byte in Control Packet RAM has its own parity bit in the Control Packet Parity RAM as shown in [Table 16-4](#), [Table 16-5](#) and [Table 16-6](#). P0 is the parity bit for byte 0, P1 is the parity bit for byte 1 and so on.

Each byte in the control packet RAM has its own parity bit in the control packet parity RAM as shown in [Table 16-4](#) and [Table 16-5](#).

**Table 16-4. Control Packet RAM**

| Bit   | 31      | 24 | 23      | 16 | 15      | 8 | 7       | 0 |
|-------|---------|----|---------|----|---------|---|---------|---|
| Word0 | Byte 0  |    | Byte 1  |    | Byte 2  |   | Byte 3  |   |
| Word1 | Byte 4  |    | Byte 5  |    | Byte 6  |   | Byte 7  |   |
| Word2 | Byte 8  |    | Byte 9  |    | Byte 10 |   | Byte 11 |   |
| Word3 | Byte 12 |    | Byte 13 |    | Byte 14 |   | Byte 15 |   |

**Table 16-5. Control Packet RAM**

| Bit | 127    | 96 | 95     | 64 | 63     | 32 | 31     | 0 |
|-----|--------|----|--------|----|--------|----|--------|---|
|     | Word 3 |    | Word 2 |    | Word 1 |    | Word 0 |   |

**Table 16-6. Parity RAM**

| Bit | 15  | 14  | 13  | 12  | 11  | 10  | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
|     | P15 | P14 | P13 | P12 | P11 | P10 | P9 | P8 | P7 | P6 | P5 | P4 | P3 | P2 | P1 | P0 |

### 16.2.17 Initializing RAM with Parity

After power up, the RAM content including the parity bit cannot be guaranteed. To avoid parity failures when reading RAM, the RAM has to be initialized. The RAM can be initialized by writing known values into it. When the known value is written, the corresponding parity bit will be automatically calculated and updated.

Another possibility to initialize the memory is to set a 4-bit key in the system module. This key triggers the automatic initialization of all RAMs on the microcontroller. The RAM will be initialized to 0. Depending on the even/odd parity selection, the parity bit will be calculated accordingly.

To allow for parity calculation during initialization, the parity functionality has to be enabled as discussed in [Section 16.2.15](#).

## 16.3 Control Registers and Control Packets

The DMA control registers are summarized in [Table 16-7](#). The base address for the control registers is FFFF F000h. The control packets are summarized in [Table 16-8](#). The base address for the control packets is FFF8 0000h. Each register begins on a word boundary. All registers and control packets are accessible in 8, 16, and 32 bit.

**NOTE:** The register definitions are given for a full DMA module configuration (32 channels, 64 requests, 2 Ports, Dual CPU support). Writes and Reads of bits pertaining to features not included in the DMA implementation as defined in the device-specific data manual are possible without error; however, they will have no affect on device operation.

**Table 16-7. DMA Control Registers**

### 16.3.1 Global Configuration Registers

These registers control the overall behavior of the DMA controller.

#### 16.3.1.1 Global Control Register (GCTRL)

**Figure 16-18. Global Control Register (GCTRL) [offset = 00]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

**Table 16-9. Global Control Register (GCTRL) Field Descriptions**

| Bit   | Field      | Value               | Description                                                                                                                                                                                                                                                                                                                                                      |
|-------|------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-17 | Reserved   | 0                   | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                           |
| 16    | DMA_EN     | 0<br>1              | DMA enable bit. The configuration registers and channel control packets should be setup first before DMA_EN bit is set to one to prevent state machines from carrying out bus transactions. If DMA_EN bit is cleared in the middle of an bus transaction, the state machine will stop at an arbitration boundary.<br>The DMA is disabled.<br>The DMA is enabled. |
| 15    | Reserved   | 0                   | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                           |
| 14    | BUS BUSY   | 0<br>1              | This bit indicates status of DMA external AHB bus status.<br>DMA's external bus is not busy in data transfers.<br>DMA's external bus is busy in data transfers.                                                                                                                                                                                                  |
| 13-10 | Reserved   | 0                   | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                           |

|------|------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ENDADDRESS | 0-FFFF FFFFh | End Address defines the address at which the region ends. The end address usually is larger than the start address for this region; otherwise the region will wrap around at the end of the address space. |

### 16.3.1.65 DMA Memory Protection Region 3 Start Address Register (DMAMPR3S)

**Figure 16-82. DMA Memory Protection Region 3 Start Address Register (DMAMPR3S) [offset = 1D0h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

**Table 16-73. DMA Memory Protection Region 3 Start Address Register (DMAMPR3S) Field Descriptions**

| Bit  | Field        | Value        | Description                                                   |
|------|--------------|--------------|---------------------------------------------------------------|
| 31-0 | STARTADDRESS | 0-FFFF FFFFh | Start Address defines the address at which the region begins. |

### 16.3.1.66 DMA Memory Protection Region 3 End Address Register (DMAMPR3E)

**Figure 16-83. DMA Memory Protection Region 3 End Address Register (DMAMPR3E) [offset = 1D4h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

**Table 16-74. DMA Memory Protection Region 3 End Address Register (DMAMPR3E) Field Descriptions**

| Bit  | Field      | Value        | Description                                                                                                                                                                                                 |
|------|------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ENDADDRESS | 0-FFFF FFFFh | End Address defines the address at which the region ends. The end address usually is larger than the start address for this region; otherwise, the region will wrap around at the end of the address space. |

### 16.3.2 Channel Configuration

The channel configuration is defined by the channel control packet: channel control, transfer count, index pointers, source/destination address.

- It is stored in local RAM, which is protected by parity.
- Each control packet contains a total of nine fields.
- The first six fields are programmable, while the last three fields are read only.
- The RAM is accessible by queue A and queue B state machines as well as CPU.
- When there are simultaneous accesses, the priority is resolved in a fixed priority scheme with the CPU having the highest priority.

All the control packets look the same. Following, there is the detailed layout of these registers shown for control packet 0.

#### 16.3.2.1 Initial Source Address (ISADDR)

**Figure 16-84. Initial Source Address (ISADDR) [offset = 00]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset; X = Unknown

**Table 16-75. Initial Source Address (ISADDR) Field Descriptions**

| Bit  | Field  | Value        | Description                                                                            |
|------|--------|--------------|----------------------------------------------------------------------------------------|
| 31-0 | ISADDR | 0-FFFF FFFFh | Initial source address. These bits give the absolute 32-bit source address (physical). |

### 16.3.2.2 Initial Destination Address Register (IDADDR)

**Figure 16-85. Initial Destination Address Register (IDADDR) [offset = 04h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset; X = Unknown

**Table 16-76. Initial Destination Address Register (IDADDR) Field Descriptions**

| Bit  | Field  | Value        | Description                                                                                      |
|------|--------|--------------|--------------------------------------------------------------------------------------------------|
| 31-0 | IDADDR | 0-FFFF FFFFh | Initial destination address. These bits give the absolute 32-bit destination address (physical). |

### 16.3.2.3 Initial Transfer Count Register (ITCOUNT)

**Figure 16-86. Initial Transfer Count Register (ITCOUNT) [offset = 08h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset; X = Unknown

**Table 16-77. Initial Transfer Count Register (ITCOUNT) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                            |
|-------|----------|---------|----------------------------------------------------------------------------------------------------------------------------------------|
| 31-29 | Reserved | 0       | Reads are undefined. Writes have no effect.                                                                                            |
| 28-16 | IFTCOUNT | 0-1FFFh | Initial frame transfer count. These bits define the number of frame transfers.                                                         |
| 15-13 | Reserved | 0       | Reads are undefined. Writes have no effect.                                                                                            |
| 12-0  | IETCOUNT | 0-1FFFh | Initial element transfer count. These bits define the number of element transfers. The block transfer size will be IETCOUNT x IFTCOUNT |

#### 16.3.2.4 Channel Control Register (CHCTRL)

**Figure 16-87. Channel Control Register (CHCTRL) [offset = 10h]**

|          |  |  |  |  |        |  |  |  |  |          |  |  |  |  |         |  |  |  |  |          |  |  |  |  |        |  |  |  |  |        |  |  |  |  |        |  |  |  |  |   |  |  |  |  |   |  |  |  |  |   |  |  |  |  |   |  |  |  |  |   |  |  |  |  |   |  |  |  |  |

| Reserved |    | CETCOUNT |    |
| R-X      |    | R-X      |    |

LEGEND: R = Read only; -n = value after reset; X = Unknown

**Table 16-83. Current Transfer Count Register (CTCOUNT) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                       |
|-------|----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-29 | Reserved | 0       | Reads are undefined. Writes have no effect.                                                                                                                                       |
| 28-16 | CFTCOUNT | 0-1FFFh | Current frame transfer count. Returned the current remaining frame counts.                                                                                                        |
| 15-13 | Reserved | 0       | Reads are undefined. Writes have no effect.                                                                                                                                       |
| 12-0  | CETCOUNT | 0-1FFFh | Current element transfer count. These bits return the current remaining element counts. CTCOUNT register is only updated after a channel is arbitrated out of the priority queue. |

## ***External Memory Interface (EMIF)***

---

---

This chapter describes the external memory Interface (EMIF).

| <b>Topic</b>                               | <b>Page</b> |
|--------------------------------------------|-------------|
| <b>17.1 Introduction .....</b>             | <b>622</b>  |
| <b>17.2 EMIF Module Architecture .....</b> | <b>624</b>  |
| <b>17.3 Registers .....</b>                | <b>656</b>  |
| <b>17.4 Example Configuration .....</b>    | <b>668</b>  |

## 17.1 Introduction

### 17.1.1 Purpose of the Peripheral

This EMIF memory controller is compliant with the JESD21-C SDR SDRAM memories utilizing a 16-bit data bus. The purpose of this EMIF is to provide a means for the CPU to connect to a variety of external devices including:

- Single data rate (SDR) SDRAM
- Asynchronous devices including NOR Flash and SRAM

The most common use for the EMIF is to interface with both a flash device and an SDRAM device simultaneously. contains an example of operating the EMIF in this configuration.

### 17.1.2 Features

The EMIF includes many features to enhance the ease and flexibility of connecting to external SDR SDRAM and asynchronous devices.

#### 17.1.2.1 Asynchronous Memory Support

EMIF supports asynchronous:

- SRAM memories
- NOR Flash memories

The EMIF data bus width is up to 16 bits and there are up to 22 address lines. There is an external wait input that allows slower asynchronous memories to extend the memory access. The EMIF module supports up to 3 chip selects (EMIF\_nCS[4:2]). Each chip select has the following individually programmable attributes:

- Data Bus Width
- Read cycle timings: setup, hold, strobe
- Write cycle timings: setup, hold, strobe
- Bus turn-around time
- Extended Wait Option with Programmable Timeout
- Select Strobe option

#### 17.1.2.2 Synchronous DRAM Memory Support

The EMIF module supports 16-bit SDRAM in addition to the asynchronous memories listed in [Section 17.1.2.1](#). It has a single SDRAM chip select (EMIF\_nCS[0]). SDRAM configurations that are supported are:

- One, Two and Four Bank SDRAM devices
- Devices with Eight, Nine, Ten, and Eleven Column Address
- CAS Latency of two or three clock cycles
- 16-bit Data Bus Width
- 3.3V LVCMOS Interface

Additionally, the EMIF supports placing the SDRAM in Self-Refresh and Powerdown modes. Self-refresh mode allows the SDRAM to be put in a low-power state while still retaining memory contents; since the SDRAM will continue to refresh itself even without clocks from the microcontroller. Powerdown mode achieves even lower power, except the microcontroller must periodically wake up and issue refreshes if data retention is required.

Note that the EMIF module does not support Mobile SDRAM devices.

### 17.1.3 Functional Block Diagram

Figure 17-1 illustrates the connections between the EMIF and its internal requesters, along with the external EMIF pins. Section 17.2.2 contains a description of the entities internal to the SoC that can send requests to the EMIF, along with their prioritization. Section 17.2.3 describes the EMIF external pins and summarizes their purpose when interfacing with SDRAM and asynchronous devices.

**Figure 17-1. EMIF Functional Block Diagram**

## 17.2 EMIF Module Architecture

This section provides details about the architecture and operation of the EMIF. Both, SDRAM and asynchronous Interface are covered, along with other system-related issues such as clock control.

### 17.2.1 EMIF Clock Control

The EMIF clock is output on the EMIF\_CLK pin and should be used when interfacing to external SDRAM devices. The EMIF module gets the VCLK3 clock domain as the input. This clock domain is running at half the frequency of the main oscillator by default, that is, between 2.5MHz to 10MHz. The VCLK3 frequency is divided down from the HCLK domain frequency by a programmable divider (/1 to /16). Refer the Architecture chapter of the device technical reference manual for more information on configuring the VCLK3 domain frequency.

### 17.2.2 EMIF Requests

Different sources within the SoC can make requests to the EMIF. These requests consist of accesses to SDRAM memory, asynchronous memory, and EMIF registers. The EMIF can process only one request at a time. Therefore a high performance crossbar switch exists within the SoC to provide prioritized requests from the different sources to the EMIF. The sources are:

1. CPU
2. DMA
3. Other master peripherals

If a request is submitted from two or more sources simultaneously, the crossbar switch will forward the highest priority request to the EMIF first. Upon completion of a request, the crossbar switch again evaluates the pending requests and forwards the highest priority pending request to the EMIF.

When the EMIF receives a request, it may or may not be immediately processed. In some cases, the EMIF will perform one or more auto refresh cycles before processing the request. For details on the EMIF's internal arbitration between performing requests and performing auto refresh cycles, see [Section 17.2.13](#).

### 17.2.3 EMIF Signal Descriptions

This section describes the function of each of the EMIF signals.

**Table 17-1. EMIF Pins Used to Access Both SDRAM and Asynchronous Memories**

| Pins(s)        | I/O | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

The mapping from the internal program address to the external values placed on these pins can be found in <a href="#">Table 17-13</a> .<br>When interfacing to an asynchronous device, these pins are used in conjunction with the EMIF_A pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins can be found in <a href="#">Section 17.2.6.1</a> .                                                                                                  |
| EMIF_nDQM[1:0] | O   | <b>Active-low byte enables.</b><br>When interfacing to SDRAM, these pins are connected to the DQM pins of the SDRAM to individually enable/disable each of the bytes in a data access.<br>When interfacing to an asynchronous device, these pins are connected to byte enables. See <a href="#">Section 17.2.6</a> for details.                                                                                                                                                                                                                                                                                                                                                     |

**Table 17-1. EMIF Pins Used to Access Both SDRAM and Asynchronous Memories (continued)**

| Pin(s)   | I/O | Description                                                                                                                                                                                                                                                                                                               |
|----------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EMIF_nWE | O   | <b>Active-low write enable.</b><br>When interfacing to SDRAM, this pin is connected to the nWE pin of the SDRAM and is used to send commands to the device.<br>When interfacing to an asynchronous device, this pin provides a signal which is active-low during the strobe period of an asynchronous write access cycle. |

**Table 17-2. EMIF Pins Specific to SDRAM**

| Pin(s)      | I/O | Description                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EMIF_nCS[0] | O   | <b>Active-low chip enable pin for SDRAM devices.</b><br>This pin is connected to the chip-select pin of the attached SDRAM device and is used for enabling/disabling commands. By default, the EMIF keeps this SDRAM chip select active, even if the EMIF is not interfaced with an SDRAM device. This pin is deactivated when accessing the asynchronous memory bank and is reactivated on completion of the asynchronous access. |
| EMIF_nRAS   | O   | <b>Active-low row address strobe pin.</b><br>This pin is connected to the nRAS pin of the attached SDRAM device and is used for sending commands to the device.                                                                                                                                                                                                                                                                    |
| EMIF_nCAS   | O   | <b>Active-low column address strobe pin.</b><br>This pin is connected to the nCAS pin of the attached SDRAM device and is used for sending commands to the device.                                                                                                                                                                                                                                                                 |
| EMIF_CKE    | O   | <b>Clock enable pin.</b><br>This pin is connected to the CKE pin of the attached SDRAM device and is used for issuing the SELF REFRESH command which places the device in self refresh mode. See <a href="#">Section 17.2.5.7</a> for details.                                                                                                                                                                                     |
| EMIF_CLK    | O   | <b>SDRAM clock pin.</b><br>This pin is connected to the CLK pin of the attached SDRAM device. See <a href="#">Section 17.2.1</a> for details on the clock signal.                                                                                                                                                                                                                                                                  |

**Table 17-3. EMIF Pins Specific to Asynchronous Memory**

| Pin(s)        | I/O | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EMIF_nCS[4:2] | O   | <b>Active-low chip enable pins for asynchronous devices.</b><br>These pins are meant to be connected to the chip-select pins of the attached asynchronous device. These pins are active only during accesses to the asynchronous memory.                                                                                                                                                                                                               |
| EMIF_nWAIT    | I   | <b>Wait input with programmable polarity.</b><br>A connected asynchronous device can extend the strobe period of an access cycle by asserting the EMIF_nWAIT input to the EMIF as described in <a href="#">Section 17.2.6.6</a> . To enable this functionality, the EW bit in the asynchronous 1 configuration register (CE2CFG) must be set to 1. In addition, the WPO bit in CE2CFG must be configured to define the polarity of the EMIF_nWAIT pin. |
| EMIF_nOE      | O   | <b>Active-low pin enable for asynchronous devices.</b><br>This pin provides a signal which is active-low during the strobe period of an asynchronous read access cycle.                                                                                                                                                                                                                                                                                |
| EMIF_RnW      | O   | <b>EMIF asynchronous read/write control.</b><br>This pin stays high during reads and stays low during writes (same duration as CS).                                                                                                                                                                                                                                                                                                                    |

## 17.2.4 EMIF Signal Multiplexing Control

Several EMIF signals are multiplexed with other functions on this microcontroller. Please refer to the I/O Multiplexing Module chapter of the technical reference manual for more information on how to enable the output of these EMIF signals.

## 17.2.5 SDRAM Controller and Interface

The EMIF can gluelessly interface to most standard SDR SDRAM devices and supports such features as self refresh mode and prioritized refresh. In addition, it provides flexibility through programmable parameters such as the refresh rate, CAS latency, and many SDRAM timing parameters. The following sections include details on how to Interface and properly configure the EMIF to perform read and write operations to externally connected SDR SDRAM devices. Also, provides a detailed example of interfacing the EMIF to a common SDRAM device.

### 17.2.5.1 SDRAM Commands

The EMIF supports the SDRAM commands described in [Table 17-4](#). [Table 17-5](#) shows the truth table for the SDRAM commands, and an example timing waveform of the PRE command is shown in [Figure 17-2](#). EMIF\_A[10] is pulled low in this example to deactivate only the bank specified by the EMIF\_BA pins.

**Table 17-4. EMIF SDRAM Commands**

| Command | Function                                                                                                                                                                                                                                           |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRE     | <b>Precharge.</b> Depending on the value of EMIF_A[10], the PRE command either deactivates the open row in all banks (EMIF_A[10] = 1) or only the bank specified by the EMIF_BA[1:0] pins (EMIF_A[10] = 0).                                        |
| ACTV    | <b>Activate.</b> The ACTV command activates the selected row in a particular bank for the current access.                                                                                                                                          |
| READ    | <b>Read.</b> The READ command outputs the starting column address and signals the SDRAM to begin the burst read operation. Address EMIF_A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance.  |
| WRT     | <b>Write.</b> The WRT command outputs the starting column address and signals the SDRAM to begin the burst write operation. Address EMIF_A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance. |
| BT      | <b>Burst terminate.</b> The BT command is used to truncate the current read or write burst request.                                                                                                                                                |
| LMR     | <b>Load mode register.</b> The LMR command sets the mode register of the attached SDRAM devices and is only issued during the SDRAM initialization sequence described in <a href="#">Section 17.2.5.4</a> .                                        |
| REFR    | <b>Auto refresh.</b> The REFR command signals the SDRAM to perform an auto refresh according to its internal address.                                                                                                                              |
| SLFR    | <b>Self refresh.</b> The self refresh command places the SDRAM into self refresh mode, during which it provides its own clock signal and auto refresh cycles.                                                                                      |
| NOP     | <b>No operation.</b> The NOP command is issued during all cycles in which one of the above commands is not issued.                                                                                                                                 |

**Table 17-5. Truth Table for SDRAM Commands**

| SDRAM Pins: | CKE      | nCS         | nRAS      | nCAS      | nWE      | BA[1:0]      | A[12:11]      | A[10]      | A[9:0]      |

| ACTV        | H        | L           | L         | H         | H        | Bank         | Row           | Row        | Row         |
| READ        | H        | L           | H         | L         | H        | Bank         | Column        | L          | Column      |
| WRT         | H        | L           | H         | L         | L        | Bank         | Column        | L          | Column      |
| BT          | H        | L           | H         | H         | L        | X            | X             | X          | X           |
| LMR         | H        | L           | L         | L         | L        | X            | Mode          | Mode       | Mode        |
| REFR        | H        | L           | L         | L         | H        | X            | X             | X          | X           |
| SLFR        | L        | L           | L         | L         | H        | X            | X             | X          | X           |
| NOP         | H        | L           | H         | H         | H        | X            | X             | X          | X           |

**Figure 17-2. Timing Waveform of SDRAM PRE Command**

### 17.2.5.2 Interfacing to SDRAM

The EMIF supports a glueless interface to SDRAM devices with the following characteristics:

- Pre-charge bit is A[10]
- The number of column address bits is 8, 9, 10, or 11.
- The number of row address bits is 13, 14, 15, or 16.
- The number of internal banks is 1, 2, or 4.

Figure 17-3 shows an interface between the EMIF and a 2M × 16 × 4 bank SDRAM device, and Figure 17-4 shows an interface between the EMIF and a 512K × 16 × 2 bank SDRAM device. For devices supporting 16-bit interface, refer to Table 17-6 for list of commonly-supported SDRAM devices and the required connections for the address pins.

**Figure 17-3. EMIF to 2M × 16 × 4 bank SDRAM Interface**

**Figure 17-4. EMIF to 512K × 16 × 2 bank SDRAM Interface**

**Table 17-6. 16-bit EMIF Address Pin Connections**

| SDRAM Size | Width | Banks | Device | Address Pins |
|------------|-------|-------|--------|--------------|
| 16M bits   | ×16   | 2     | SDRAM  | A[10:0]      |
|            |       |       | EMIF   | EMIF_A[10:0] |
| 64M bits   | ×16   | 4     | SDRAM  | A[11:0]      |
|            |       |       | EMIF   | EMIF_A[11:0] |
| 128M bits  | ×16   | 4     | SDRAM  | A[11:0]      |
|            |       |       | EMIF   | EMIF_A[11:0] |
| 256M bits  | ×16   | 4     | SDRAM  | A[12:0]      |
|            |       |       | EMIF   | EMIF_A[12:0] |
| 512M bits  | ×16   | 4     | SDRAM  | A[12:0]      |

### 17.2.5.3 SDRAM Configuration Registers

The operation of the EMIF's SDRAM interface is controlled by programming the appropriate configuration registers. This section describes the purpose and function of each configuration register, but [Section 17.3](#) should be referred for a more detailed description of each register, including the default registers values and bit-field positions. The following tables list the four such configuration registers, along with a description of each of their programmable fields.

**NOTE:** Writing to any of the fields: NM, CL, IBANK, and PAGESIZE in the SDRAM configuration register (SDCR) causes the EMIF to abandon whatever it is currently doing and trigger the SDRAM initialization procedure described in [Section 17.2.5.4](#).

**Table 17-7. Description of the SDRAM Configuration Register (SDCR)**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SR        | This bit controls entering and exiting of the Self-Refresh mode. The field should be written using a byte-write to the upper byte of SDCR to avoid triggering the SDRAM initialization sequence.                                                                                                                                                                                                                                                                                                                                                                                                |
| PD        | This bit controls entering and exiting of the Power down mode. The field should be written using a byte-write to the upper byte of SDCR to avoid triggering the SDRAM initialization sequence. If both SR and PD bits are set, the EMIF will go into Self Refresh.                                                                                                                                                                                                                                                                                                                              |
| PDWR      | Perform refreshes during Power Down. Writing a 1 to this bit will cause the EMIF to exit the power down state and issue an AUTO REFRESH command every time Refresh May level is set. The field should be written using a byte-write to the upper byte of SDCR to avoid triggering the SDRAM initialization sequence. This bit should be set along with PD when entering power-down mode.                                                                                                                                                                                                        |
| NM        | <b>Narrow Mode.</b> This bit defines the width of the data bus between the EMIF and the attached SDRAM device. When set to 1, the data bus is set to 16-bits. When set to 0, the data bus is set to 32-bits. This bit must always be set to 1.                                                                                                                                                                                                                                                                                                                                                  |
| CL        | <b>CAS latency.</b> This field defines the number of clock cycles between when an SDRAM issues a READ command and when the first piece of data appears on the bus. The value in this field is sent to the attached SDRAM device via the LOAD MODE REGISTER command during the SDRAM initialization procedure as described in <a href="#">Section 17.2.5.4</a> . Only, values of 2h (CAS latency = 2) and 3h (CAS latency = 3) are supported and should be written to this field. A 1 must be simultaneously written to the BIT11_9LOCK bit field of SDCR in order to write to the CL bit field. |
| IBANK     | <b>Number of Internal SDRAM Banks.</b> This field defines the number of banks inside the attached SDRAM devices in the following way: <ul style="list-style-type: none"> <li>When IBANK = 0, 1 internal bank is used</li> <li>When IBANK = 1h, 2 internal banks are used</li> <li>When IBANK = 2h, 4 internal banks are used</li> </ul> This field value affects the mapping of logical addresses to SDRAM row, column, and bank addresses. See <a href="#">Section 17.2.5.11</a> for details.                                                                                                  |
| PAGESIZE  | <b>Page Size.</b> This field defines the internal page size of the attached SDRAM devices in the following way: <ul style="list-style-type: none"> <li>When PAGESIZE = 0, 256-word pages are used</li> <li>When PAGESIZE = 1h, 512-word pages are used</li> <li>When PAGESIZE = 2h, 1024-word pages are used</li> <li>When PAGESIZE = 3h, 2048-word pages are used</li> </ul> This field value affects the mapping of logical addresses to SDRAM row, column, and bank addresses. See <a href="#">Section 17.2.5.11</a> for details.                                                            |

**Table 17-8. Description of the SDRAM Refresh Control Register (SDRCR)**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RR        | <b>Refresh Rate.</b> This field controls the rate at which attached SDRAM devices will be refreshed. The following equation can be used to determine the required value of RR for an SDRAM device: <ul style="list-style-type: none"> <li><math>RR = f_{EMIF\_CLK} / (\text{Required SDRAM Refresh Rate})</math></li> </ul> More information about the operation of the SDRAM refresh controller can be found in <a href="#">Section 17.2.5.6</a> . |

**Table 17-9. Description of the SDRAM Timing Register (SDTIMR)**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T_RFC     | <b>SDRAM Timing Parameters.</b> These fields configure the EMIF to comply with the AC timing requirements of the attached SDRAM devices. This allows the EMIF to avoid violating SDRAM timing constraints and to more efficiently schedule its operations. More details about each of these parameters can be found in the register description in <a href="#">Section 17.3.6</a> . These parameters should be set to satisfy the corresponding timing requirements found in the SDRAM's datasheet. |
| T_RP      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| T_RCD     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| T_WR      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| T_RAS     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| T_RC      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| T_RRD     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 17-10. Description of the SDRAM Self Refresh Exit Timing Register (SDSRETR)**

| Parameter | Description                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T_XS      | <b>Self Refresh Exit Parameter.</b> The T_XS field of this register informs the EMIF about the minimum number of EMIF_CLK cycles required between exiting Self Refresh and issuing any command. This parameter should be set to satisfy the $t_{XSR}$ value for the attached SDRAM device. |

#### 17.2.5.4 SDRAM Auto-Initialization Sequence

The EMIF automatically performs an SDRAM initialization sequence, regardless of whether it is interfaced to an SDRAM device, when either of the following two events occur:

- The EMIF comes out of reset. No memory accesses to the SDRAM and Asynchronous interfaces are performed until this auto-initialization is complete.
- A write is performed to any of the three least significant bytes of the SDRAM configuration register (SDCR)

An SDRAM initialization sequence consists of the following steps:

1. If the initialization sequence is activated by a write to SDCR, and if any of the SDRAM banks are open, the EMIF issues a PRE command with EMIF\_A[10] held high to indicate all banks. This is done so that the maximum ACTV to PRE timing for an SDRAM is not violated.
2. The EMIF drives EMIF\_CKE high and begins continuously issuing NOP commands until eight SDRAM refresh intervals have elapsed. An SDRAM refresh interval is equal to the value of the RR field of SDRAM refresh control register (SDRCR), divided by the frequency of EMIF\_CLK ( $RR/f_{EMIF\_CLK}$ ). This step is used to avoid violating the Power-up constraint of most SDRAM devices that requires 200  $\mu$ s (sometimes 100  $\mu$ s) between receiving stable Vdd and CLK and the issuing of a PRE command. Depending on the frequency of EMIF\_CLK, this step may or may not be sufficient to avoid violating the SDRAM constraint. See [Section 17.2.5.5](#) for more information.
3. After the refresh intervals have elapsed, the EMIF issues a PRE command with EMIF\_A[10] held high to indicate all banks.
4. The EMIF issues eight AUTO REFRESH commands.
5. The EMIF issues the LMR command with the EMIF\_A[9:0] pins set as described in [Table 17-11](#).
6. Finally, the EMIF performs a refresh cycle, which consists of the following steps:
  - (a) Issuing a PRE command with EMIF\_A[10] held high if any banks are open
  - (b) Issuing an REF command

**Table 17-11. SDRAM LOAD MODE REGISTER Command**

| EMIF_A[9:7]                                                        | EMIF_A[6:4]                                                                                                                                                                                                                                                                                     | EMIF_A[3]                                                       | EMIF_A[2:0]                                                                                                                                                                                                                                                                                            |
|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (Write bursts are of the programmed burst length in EMIF_A[2:0]) | These bits control the CAS latency of the SDRAM and are set according to CL field in the SDRAM configuration register (SDCR) as follows: <ul style="list-style-type: none"> <li>If CL = 2, EMIF_A[6:4] = 2h (CAS latency = 2)</li> <li>If CL = 3, EMIF_A[6:4] = 3h (CAS latency = 3)</li> </ul> | 0 (Sequential Burst Type. Interleaved Burst Type not supported) | These bits control the burst length of the SDRAM and are set according to the NM field in the SDRAM configuration register (SDCR) as follows: <ul style="list-style-type: none"> <li>If NM = 0, EMIF_A[2:0] = 2h (Burst Length = 4)</li> <li>If NM = 1, EMIF_A[2:0] = 3h (Burst Length = 8)</li> </ul> |

### 17.2.5.5 SDRAM Configuration Procedure

There are two different SDRAM configuration procedures. Although EMIF automatically performs the SDRAM initialization sequence described in [Section 17.2.5.4](#) when coming out of reset, it is recommended to follow one of the procedures listed below before performing any EMIF memory requests. Procedure A should be followed if it is determined that the SDRAM Power-up constraint was not violated during the SDRAM Auto-Initialization Sequence detailed in [Section 17.2.5.4](#) on coming out of Reset. The SDRAM Power-up constraint specifies that 200  $\mu$ s (sometimes 100  $\mu$ s) should exist between receiving stable Vdd and CLK and the issuing of a PRE command. Procedure B should be followed if the SDRAM Power-up constraint was violated. The 200  $\mu$ s (100  $\mu$ s) SDRAM Power-up constraint will be violated if the frequency of EMIF\_CLK is greater than 50 MHz (100 MHz for 100  $\mu$ s SDRAM power-up constraint) during SDRAM Auto-Initialization Sequence. Procedure B should be followed if there is any doubt that the Power-up constraint was not met.

**Procedure A** — Following is the procedure to be followed if the SDRAM Power-up constraint was NOT violated:

1. Place the SDRAM into Self-Refresh Mode by setting the SR bit of SDCR to 1. A byte-write to the upper byte of SDCR should be used to avoid restarting the SDRAM Auto-Initialization Sequence described in [Section 17.2.5.4](#). The SDRAM should be placed into Self-Refresh mode when changing the frequency of EMIF\_CLK to avoid incurring the 200  $\mu$ s Power-up constraint again.
2. Configure the desired EMIF\_CLK clock frequency. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device datasheet.
3. Remove the SDRAM from Self-Refresh Mode by clearing the SR bit of SDCR to 0. A byte-write to the upper byte of SDCR should be used to avoid restarting the SDRAM Auto-Initialization Sequence described in [Section 17.2.5.4](#).
4. Program SDTIMR and SDSRETR to satisfy the timing requirements for the attached SDRAM device. The timing parameters should be taken from the SDRAM datasheet.
5. Program the RR field of SDRCCR to match that of the attached device's refresh interval. See [Section 17.2.5.6.1](#) details on determining the appropriate value.
6. Program SDCR to match the characteristics of the attached SDRAM device. This will cause the auto-initialization sequence in [Section 17.2.5.4](#) to be re-run. This second initialization generally takes much less time due to the increased frequency of EMIF\_CLK.

**Procedure B** — Following is the procedure to be followed if the SDRAM Power-up constraint was violated:

1. Configure the desired EMIF\_CLK clock frequency. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device datasheet.
2. Program SDTIMR and SDSRETR to satisfy the timing requirements for the attached SDRAM device. The timing parameters should be taken from the SDRAM datasheet.
3. Program the RR field of SDRCCR such that the following equation is satisfied:  $(RR \times 8)/(f_{EMIF\_CLK}) > 200 \mu s$  (sometimes 100  $\mu$ s). For example, an EMIF\_CLK frequency of 100 MHz would require setting RR to 2501 (9C5h) or higher to meet a 200  $\mu$ s constraint.

4. Program SDCR to match the characteristics of the attached SDRAM device. This will cause the auto-initialization sequence in [Section 17.2.5.4](#) to be re-run with the new value of RR.
5. Perform a read from the SDRAM to assure that step 5 of this procedure will occur after the initialization process has completed. Alternatively, wait for 200  $\mu$ s instead of performing a read.
6. Finally, program the RR field to match that of the attached device's refresh interval. See [Section 17.2.5.6.1](#) details on determining the appropriate value.

After following the above procedure, the EMIF is ready to perform accesses to the attached SDRAM device. See for an example of configuring the SDRAM interface.

### 17.2.5.6 EMIF Refresh Controller

An SDRAM device requires that each of its rows be refreshed at a minimum required rate. The EMIF can meet this constraint by performing auto refresh cycles at or above this required rate. An auto refresh cycle consists of issuing a PRE command to all banks of the SDRAM device followed by issuing a REFR command. To inform the EMIF of the required rate for performing auto refresh cycles, the RR field of the SDRAM refresh control register (SDRCR) must be programmed. The EMIF will use this value along with two internal counters to automatically perform auto refresh cycles at the required rate. The auto refresh cycles cannot be disabled, even if the EMIF is not interfaced with an SDRAM. The remainder of this section details the EMIF's refresh scheme and provides an example for determining the appropriate value to place in the RR field of SDRCR.

The two counters used to perform auto-refresh cycles are a 13-bit refresh interval counter and a 4-bit refresh backlog counter. At reset and upon writing to the RR field, the refresh interval counter is loaded with the value from RR field and begins decrementing, by one, each EMIF clock cycle. When the refresh interval counter reaches zero, the following actions occur:

- The refresh interval counter is reloaded with the value from the RR field and restarts decrementing.
- The 4-bit refresh backlog counter increments unless it has already reached its maximum value.

The refresh backlog counter records the number of auto refresh cycles that the EMIF currently has outstanding. This counter is decremented by one each time an auto refresh cycle is performed and incremented by one each time the refresh interval counter expires. The refresh backlog counter saturates at the values of 0000b and 1111b. The EMIF uses the refresh backlog counter to determine the urgency with which an auto refresh cycle should be performed. The four levels of urgency are described in [Table 17-12](#). This refresh scheme allows the required refreshes to be performed with minimal impact on access requests.

**Table 17-12. Refresh Urgency Levels**

| Urgency Level   | Refresh Backlog Counter Range | Action Taken                                                                                                                                                                                                       |
|-----------------|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Refresh May     | 1-3                           | An auto-refresh cycle is performed only if the EMIF has no requests pending and none of the SDRAM banks are open.                                                                                                  |
| Refresh Release | 4-7                           | An auto-refresh cycle is performed if the EMIF has no requests pending, regardless of whether any SDRAM banks are open.                                                                                            |
| Refresh Need    | 8-11                          | An auto-refresh cycle is performed at the completion of the current access unless there are read requests pending.                                                                                                 |
| Refresh Must    | 12-15                         | Multiple auto-refresh cycles are performed at the completion of the current access until the Refresh Release urgency level is reached. At that point, the EMIF can begin servicing any new read or write requests. |

### 17.2.5.6.1 Determining the Appropriate Value for the RR Field

The value that should be programmed into the RR field of SDCR can be calculated by using the frequency of the EMIF\_CLK signal ( $f_{\text{EMIF\_CLK}}$ ) and the required refresh rate of the SDRAM ( $f_{\text{Refresh}}$ ). The following formula can be used:

$$RR = f_{\text{EMIF\_CLK}} / f_{\text{Refresh}}$$

The SDRAM datasheet often communicates the required SDRAM Refresh Rate in terms of the number of REFR commands required in a given time interval. The required SDRAM Refresh Rate in the formula above can therefore be calculated by dividing the number of required cycles per time interval ( $n_{\text{cycles}}$ ) by the time interval given in the datasheet ( $t_{\text{Refresh Period}}$ ):

$$f_{\text{Refresh}} = n_{\text{cycles}} / t_{\text{Refresh Period}}$$

Combining these formulas, the value that should be programmed into the RR field can be computed as:

$$RR = f_{\text{EMIF\_CLK}} \times t_{\text{Refresh Period}} / n_{\text{cycles}}$$

The following example illustrates calculating the value of RR. Given that:

- $f_{\text{EMIF\_CLK}} = 100 \text{ MHz}$  (frequency of the EMIF clock)
- $t_{\text{Refresh Period}} = 64 \text{ ms}$  (required refresh interval of the SDRAM)
- $n_{\text{cycles}} = 8192$  (number of cycles in a refresh interval for the SDRAM)

RR can be calculated as:

$$RR = 100 \text{ MHz} \times 64 \text{ ms} / 8192$$

$$RR = 781.25$$

$$RR = 782 \text{ cycles} = 30\text{Eh cycles}$$

### 17.2.5.7 Self-Refresh Mode

The EMIF can be programmed to enter the self-refresh state by setting the SR bit of SDCR to 1. This will cause the EMIF to issue the SLFR command after completing any outstanding SDRAM access requests and clearing the refresh backlog counter by performing one or more auto refresh cycles. This places the attached SDRAM device into self-refresh mode in which it consumes a minimal amount of power while performing its own refresh cycles. The SR bit should be set and cleared using a byte-write to the upper byte of the SDRAM configuration register (SDCR) to avoid triggering the SDRAM initialization sequence.

While in the self-refresh state, the EMIF continues to service asynchronous bank requests and register accesses as normal, with one caveat. The EMIF will not park the data bus following a read to asynchronous memory while in the self-refresh state. Instead, the EMIF tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIF is in the self-refresh state, in order to prevent floating inputs on the data bus. More information about data bus parking can be found in [Section 17.2.7](#).

The EMIF will exit from the self-refresh state if either of the following events occur:

- The SR bit of SDCR is cleared to 0.
- An SDRAM accesses is requested.

The EMIF exits from the self-refresh state by driving EMIF\_CKE high and performing an auto refresh cycle.

The attached SDRAM device should also be placed into Self-Refresh Mode when changing the frequency of EMIF\_CLK. If the frequency of EMIF\_CLK changes while the SDRAM is not in Self-Refresh Mode, Procedure B in [Section 17.2.5.5](#) should be followed to reinitialize the device.

### 17.2.5.8 Power Down Mode

To support low-power modes, the EMIF can be requested to issue a POWER DOWN command to the SDRAM by setting the PD bit in the SDRAM configuration register (SDCR). When this bit is set, the EMIF will continue normal operation until all outstanding memory access requests have been serviced and the SDRAM refresh backlog (if there is one) has been cleared. At this point the EMIF will enter the power-down state. Upon entering this state, the EMIF will issue a POWER DOWN command (same as a NOP command but driving EMIF\_CKE low on the same cycle). The EMIF then maintains EMIF\_CKE low until it exits the power-down state.

Since the EMIF services the refresh backlog before it enters the power-down state, all internal banks of the SDRAM are closed (precharged) prior to issuing the POWER DOWN command. Therefore, the EMIF only supports Precharge Power Down. The EMIF does not support Active Power Down, where internal banks of the SDRAM are open (active) before the POWER DOWN command is issued.

During the power-down state, the EMIF services the SDRAM, asynchronous memory, and register accesses as normal, returning to the power-down state upon completion.

The PDWR bit in SDCR indicates whether the EMIF should perform refreshes in power-down state. If the PDWR bit is set, the EMIF exits the power-down state every time the Refresh Must level is set, performs AUTO REFRESH commands to the SDRAM, and returns back to the power-down state. This evenly distributes the refreshes to the SDRAM in power-down state. If the PDWR bit is not set, the EMIF does not perform any refreshes to the SDRAM. Therefore, the data integrity of the SDRAM is not assured upon power down exit if the PDWR bit is not set.

If the PD bit is cleared while in the power-down state, the EMIF will come out of the power-down state. The EMIF:

- Drives EMIF\_CKE high.
- Enters its idle state.

### 17.2.5.9 SDRAM Read Operation

When the EMIF receives a read request to SDRAM from one of the requesters listed in [Section 17.2.2](#), it performs one or more read access cycles. A read access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIF proceeds to issue a READ command while specifying the desired bank and column address. EMIF\_A[10] is held low during the READ command to avoid auto-precharging. The READ command signals the SDRAM device to start bursting data from the specified address while the EMIF issues NOP commands. Following a READ command, the CL field of the SDRAM configuration register (SDCR) defines how many delay cycles will be present before the read data appears on the data bus. This is referred to as the CAS latency.

[Figure 17-5](#) shows the signal waveforms for a basic SDRAM read operation in which a burst of data is read from a single page. When the EMIF SDRAM interface is configured to 16 bit by setting the NM bit of the SDRAM configuration register (SDCR) to 1, a burst size of eight is used. [Figure 17-5](#) shows a burst size of eight.

The EMIF will truncate a series of bursting data if the remaining addresses of the burst are not required to complete the request. The EMIF can truncate the burst in three ways:

- By issuing another READ to the same page in the same bank.
- By issuing a PRE command in order to prepare for accessing a different page of the same bank.
- By issuing a BT command in order to prepare for accessing a page in a different bank.

**Figure 17-5. Timing Waveform for Basic SDRAM Read Operation**

Several other pins are also active during a read access. The EMIF\_nDQM[1:0] pins are driven low during the READ commands and are kept low during the NOP commands that correspond to the burst request. The state of the other EMIF pins during each command can be found in [Table 17-5](#).

The EMIF schedules its commands based on the timing information that is provided to it in the SDRAM timing register (SDTIMR). The values for the timing parameters in this register should be chosen to satisfy the timing requirements listed in the SDRAM datasheet. The EMIF uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands between various commands during an access. Refer to the register description of SDTIMR in [Section 17.3.6](#) for more details on the various timing parameters.

### 17.2.5.10 SDRAM Write Operations

When the EMIF receives a write request to SDRAM from one of the requesters listed in [Section 17.2.2](#), it performs one or more write-access cycles. A write-access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIF proceeds to issue a WRT command while specifying the desired bank and column address. EMIF\_A[10] is held low during the WRT command to avoid auto-precharging. The WRT command signals the SDRAM device to start writing a burst of data to the specified address while the EMIF issues NOP commands. The associated write data will be placed on the data bus in the cycle concurrent with the WRT command and with subsequent burst continuation NOP commands.

[Figure 17-6](#) shows the signal waveforms for a basic SDRAM write operation in which a burst of data is read from a single page. When the EMIF SDRAM interface is configured to 16-bit by setting the NM bit of the SDRAM configuration register (SDCR) to 1, a burst size of eight is used. [Figure 17-6](#) shows a burst size of eight.

**Figure 17-6. Timing Waveform for Basic SDRAM Write Operation**

The EMIF will truncate a series of bursting data if the remaining addresses of the burst are not part of the write request. The EMIF can truncate the burst in three ways:

- By issuing another WRT to the same page
- By issuing a PRE command in order to prepare for accessing a different page of the same bank
- By issuing a BT command in order to prepare for accessing a page in a different bank

Several other pins are also active during a write access. The EMIF\_nDQM[1:0] pins are driven to select which bytes of the data word will be written to the SDRAM device. They are also used to mask out entire undesired data words during a burst access. The state of the other EMIF pins during each command can be found in [Table 17-5](#).

The EMIF schedules its commands based on the timing information that is provided to it in the SDRAM timing register (SDTIMR). The values for the timing parameters in this register should be chosen to satisfy the timing requirements listed in the SDRAM datasheet. The EMIF uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands during various cycles of an access. Refer to the register description of SDTIMR in [Section 17.3.6](#) for more details on the various timing parameters.

### 17.2.5.11 Mapping from Logical Address to EMIF Pins

When the EMIF receives an SDRAM access request, it must convert the address of the access into the appropriate signals to send to the SDRAM device. The details of this address mapping are shown in [Table 17-13](#) for 16-bit operation. Using the settings of the IBANK and PAGESIZE fields of the SDRAM configuration register (SDCR), the EMIF determines which bits of the logical address will be mapped to the SDRAM row, column, and bank addresses.

As the logical address is incremented by one halfword (16-bit operation), the column address is likewise incremented by one until a page boundary is reached. When the logical address increments across a page boundary, the EMIF moves into the same page in the next bank of the attached device by incrementing the bank address EMIF\_BA and resetting the column address. The page in the previous bank is left open until it is necessary to close it. This method of traversal through the SDRAM banks helps maximize the number of open banks inside of the SDRAM and results in an efficient use of the device. There is no limitation on the number of banks that can be open at one time, but only one page within a bank can be open at a time.

The EMIF uses the EMIF\_nDQM[1:0] pins during a WRT command to mask out selected bytes or entire words. The EMIF\_nDQM[1:0] pins are always low during a READ command.

**Table 17-13. Mapping from Logical Address to EMIF Pins for 16-bit SDRAM**

| IBANK | PAGESIZE | Logical Address |    |    |    |    |    |       |    |    |    |    |   | 8:1         | 0            |
|-------|----------|-----------------|----|----|----|----|----|-------|----|----|----|----|---|-------------|--------------|
|       |          | 31:27           | 26 | 25 | 24 | 23 | 22 | 21:14 | 13 | 12 | 11 | 10 | 9 |             |              |
| 0     | 0        | -               |    |    |    |    |    |       |    |    |    |    |   | Col Address | EMIF_nDQM[0] |
| 1     | 0        | -               |    |    |    |    |    |       |    |    |    |    |   | Col Address | EMIF_nDQM[0] |
| 2     | 0        | -               |    |    |    |    |    |       |    |    |    |    |   | Col Address | EMIF_nDQM[0] |
| 0     | 1        | -               |    |    |    |    |    |       |    |    |    |    |   | Col Address | EMIF_nDQM[0] |
| 1     | 1        | -               |    |    |    |    |    |       |    |    |    |    |   | Col Address | EMIF_nDQM[0] |
| 2     | 1        | -               |    |    |    |    |    |       |    |    |    |    |   | Col Address | EMIF_nDQM[0] |
| 0     | 2        | -               |    |    |    |    |    |       |    |    |    |    |   | Col Address | EMIF_nDQM[0] |
| 1     | 2        | -               |    |    |    |    |    |       |    |    |    |    |   | Col Address | EMIF_nDQM[0] |
| 2     | 2        | -               |    |    |    |    |    |       |    |    |    |    |   | Col Address | EMIF_nDQM[0] |
| 0     | 3        | -               |    |    |    |    |    |       |    |    |    |    |   | Col Address | EMIF_nDQM[0] |
| 1     | 3        | -               |    |    |    |    |    |       |    |    |    |    |   | Col Address | EMIF_nDQM[0] |
| 2     | 3        | -               |    |    |    |    |    |       |    |    |    |    |   | Col Address | EMIF_nDQM[0] |

**NOTE:** The upper bit of the Row Address is used only when addressing 256-Mbit and 512-Mbit SDRAM memories.

## 17.2.6 Asynchronous Controller and Interface

The EMIF easily interfaces to a variety of asynchronous devices including NOR Flash, NAND Flash, and SRAM. It can be operated in two major modes (see [Table 17-14](#)):

- Normal Mode
- Select Strobe Mode

**Table 17-14. Normal Mode vs. Select Strobe Mode**

| Mode               | Function of EMIF_nDQM pins | Operation of EMIF_nCS[4:2]                              |
|--------------------|----------------------------|---------------------------------------------------------|
| Normal Mode        | Byte enables               | Active during the entire asynchronous access cycle      |
| Select Strobe Mode | Byte enables               | Active only during the strobe period of an access cycle |

The first mode of operation is Normal Mode, in which the EMIF\_nDQM pins of the EMIF function as byte enables. In this mode, the EMIF\_nCS[4:2] pins behaves as typical chip select signals, remaining active for the duration of the asynchronous access. See [Section 17.2.6.1](#) for an example interface with multiple 8-bit devices.

The second mode of operation is Select Strobe Mode, in which the EMIF\_nCS[4:2] pins act as a strobe, active only during the strobe period of an access. In this mode, the EMIF\_nDQM pins of the EMIF function as standard byte enables for reads and writes. A summary of the differences between the two modes of operation are shown in [Table 17-14](#). Refer to [Section 17.2.6.4](#) for the details of asynchronous operations in Normal Mode, and to [Section 17.2.6.5](#) for the details of asynchronous operations in Select Strobe Mode. The EMIF hardware defaults to Normal Mode, but can be manually switched to Select Strobe Mode by setting the SS bit in the asynchronous  $m$  ( $m = 1, 2, 3$ , or  $4$ ) configuration register (CE $n$ CFG) ( $n = 2, 3$ , or  $4$ ). Throughout the chapter,  $m$  can hold the values 1, 2, 3 or 4; and  $n$  can hold the values 2, 3, or 4.

The EMIF also provides configurable cycle timing parameters and an Extended Wait Mode that allows the connected device to extend the strobe period of an access cycle. The following sections describe the features related to interfacing with external asynchronous devices.

### 17.2.6.1 Interfacing to Asynchronous Memory

[Figure 17-7](#) shows the EMIF's external pins used in interfacing with an asynchronous device. In EMIF\_nCS[ $n$ ],  $n = 2, 3$ , or  $4$ .

**Figure 17-7. EMIF Asynchronous Interface**

Of special note is the connection between the EMIF and the external device's address bus. The EMIF address pin EMIF\_A[0] always provides the least significant bit of a 32-bit word address. Therefore, when interfacing to a 16-bit or 8-bit asynchronous device, the EMIF\_BA[1] and EMIF\_BA[0] pins provide the least-significant bits of the halfword or byte address, respectively. Additionally, when the EMIF interfaces to a 16-bit asynchronous device, the EMIF\_BA[0] pin can serve as the upper address line EMIF\_A[22]. Figure 17-8 and Figure 17-9 show the mapping between the EMIF and the connected device's data and address pins for various programmed data bus widths. The data bus width may be configured in the asynchronous *n* configuration register (CENCFG).

Figure 17-9 shows a common interface between the EMIF and external asynchronous memory. Figure 17-9 shows an interface between the EMIF and an external memory with byte enables. The EMIF should be operated in either Normal Mode or Select Strobe Mode when using this interface, so that the EMIF\_nDQM signals operate as byte enables.

**Figure 17-8. EMIF to 8-bit/16-bit Memory Interface**

a) EMIF to 8-bit memory interface

b) EMIF to 16-bit memory interface

**Figure 17-9. Common Asynchronous Interface**

### 17.2.6.2 Accessing Larger Asynchronous Memories

The device has 22 dedicated EMIF address lines. If a device such as a large asynchronous flash needs to be attached to the EMIF, then GPIO pins may be used to control the flash device's upper address lines.

### 17.2.6.3 Configuring the EMIF for Asynchronous Accesses

The operation of the EMIF's asynchronous interface can be configured by programming the appropriate register fields. The reset value and bit position for each register field can be found in [Section 17.3](#). The following tables list the register fields that can be programmed and describe the purpose of each field. These registers can be programmed prior to accessing the external memory, and the transfer following a write to these registers will use the new configuration.

**Table 17-15. Description of the Asynchronous *m* Configuration Register (CE<sub>n</sub>CFG)**

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SS                | <b>Select Strobe mode.</b> This bit selects the EMIF's mode of operation in the following way: <ul style="list-style-type: none"> <li>SS = 0 selects Normal Mode <ul style="list-style-type: none"> <li>EMIF_nDQM pins function as byte enables</li> <li>EMIF_nCS[4:2] active for duration of access</li> </ul> </li> <li>SS = 1 selects Select Strobe Mode <ul style="list-style-type: none"> <li>EMIF_nDQM pins function as byte enables</li> <li>EMIF_nCS[4:2] acts as a strobe.</li> </ul> </li> </ul>                                                                                                                                                                                                                                                                             |
| EW                | <b>Extended Wait Mode enable.</b> <ul style="list-style-type: none"> <li>EW = 0 disables Extended Wait Mode</li> <li>EW = 1 enables Extended Wait Mode</li> </ul> When set to 1, the EMIF enables its Extended Wait Mode in which the strobe width of an access cycle can be extended in response to the assertion of the EMIF_nWAIT pin. The WP <sub>n</sub> bit in the asynchronous wait cycle configuration register (AWCC) controls to polarity of EMIF_nWAIT pin. See <a href="#">Section 17.2.6.6</a> for more details on this mode of operation.                                                                                                                                                                                                                                |
| W_SETUP/R_SETUP   | <b>Read/Write setup widths.</b><br>These fields define the number of EMIF clock cycles of setup time for the address pins (EMIF_A and EMIF_BA), byte enables (EMIF_nDQM), and asynchronous chip enable (EMIF_nCS[4:2]) before the read strobe pin (EMIF_nOE) or write strobe pin (EMIF_nWE) falls, minus one cycle. For writes, the W_SETUP field also defines the setup time for the data pins (EMIF_D). Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field.                                                                                                                                                                                                                                                              |
| W_STROBE/R_STROBE | <b>Read/Write strobe widths.</b><br>These fields define the number of EMIF clock cycles between the falling and rising of the read strobe pin (EMIF_nOE) or write strobe pin (EMIF_nWE), minus one cycle. If Extended Wait Mode is enabled by setting the EW field in the asynchronous <i>n</i> configuration register (CE <sub>n</sub> CFG), these fields must be set to a value greater than zero. Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field.                                                                                                                                                                                                                                                                   |
| W_HOLD/R_HOLD     | <b>Read/Write hold widths.</b><br>These fields define the number of EMIF clock cycles of hold time for the address pins (EMIF_A and EMIF_BA), byte enables (EMIF_nDQM), and asynchronous chip enable (EMIF_nCS[4:2]) after the read strobe pin (EMIF_nOE) or write strobe pin (EMIF_nWE) rises, minus one cycle. For writes, the W_HOLD field also defines the hold time for the data pins (EMIF_D). Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field.                                                                                                                                                                                                                                                                   |
| TA                | <b>Minimum turnaround time.</b><br>This field defines the minimum number of EMIF clock cycles between asynchronous reads and writes, minus one cycle. The purpose of this feature is to avoid contention on the bus. The value written to this field also determines the number of cycles that will be inserted between asynchronous accesses and SDRAM accesses. Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field.                                                                                                                                                                                                                                                                                                      |
| ASIZE             | <b>Asynchronous Device Bus Width.</b><br>This field determines the data bus width of the asynchronous interface in the following way: <ul style="list-style-type: none"> <li>ASIZE = 0 selects an 8-bit bus</li> <li>ASIZE = 1 selects a 16-bit bus</li> </ul> The configuration of ASIZE determines the function of the EMIF_A and EMIF_BA pins as described in <a href="#">Section 17.2.6.1</a> . This field also determines the number of external accesses required to fulfill a request generated by one of the sources mentioned in <a href="#">Section 17.2.2</a> . For example, a request for a 32-bit word would require four external access when ASIZE = 0. Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field. |

**Table 17-16. Description of the Asynchronous Wait Cycle Configuration Register (AWCC)**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WP <sub>n</sub> | <b>EM_WAIT Polarity.</b> <ul style="list-style-type: none"> <li>WP<sub>n</sub> = 0 selects active-low polarity</li> <li>WP<sub>n</sub> = 1 selects active-high polarity</li> </ul> <p>When set to 1, the EMIF will wait if the EMIF_nWAIT pin is high. When cleared to 0, the EMIF will wait if the EMIF_nWAIT pin is low. The EMIF must have the Extended Wait Mode enabled for the EMIF_nWAIT pin to affect the width of the strobe period.</p>                                                                                                                                                                                                                                                                                                                                                                                                                            |
| MAX_EXT_WAIT    | <b>Maximum Extended Wait Cycles.</b> <p>This field configures the number of EMIF clock cycles the EMIF will wait for the EMIF_nWAIT pin to be deactivated during the strobe period of an access cycle. The maximum number of EMIF clock cycles it will wait is determined by the following formula:<br/> Maximum Extended Wait Cycles = (MAX_EXT_WAIT + 1) × 16<br/> If the EMIF_nWAIT pin is not deactivated within the time specified by this field, the EMIF resumes the access cycle, registering whatever data is on the bus and proceeding to the hold period of the access cycle. This situation is referred to as an Asynchronous Timeout. An Asynchronous Timeout generates an interrupt, if it has been enabled in the EMIF interrupt mask set register (INTMSKSET). Refer to <a href="#">Section 17.2.9.1</a> for more information about the EMIF interrupts.</p> |

**Table 17-17. Description of the EMIF Interrupt Mask Set Register (INTMSKSET)**

| Parameter   | Description                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| WR_MASK_SET | <b>Wait Rise Mask Set.</b><br>Writing a 1 enables an interrupt to be generated when a rising edge on EMIF_nWAIT occurs while in NAND Flash Mode |
| AT_MASK_SET | <b>Asynchronous Timeout Mask Set.</b><br>Writing a 1 to this bit enables an interrupt to be generated when an Asynchronous Timeout occurs.      |

**Table 17-18. Description of the EMIF Interrupt Mast Clear Register (INTMSKCLR)**

| Parameter   | Description                                                                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WR_MASK_CLR | <b>Wait Rise Mask Clear.</b><br>Writing a 1 to this bit disables the interrupt, clearing the WR_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET). |
| AT_MASK_CLR | <b>Asynchronous Timeout Mask Clear.</b><br>Writing a 1 to this bit prevents an interrupt from being generated when an Asynchronous Timeout occurs.                |

#### 17.2.6.4 Read and Write Operations in Normal Mode

Normal Mode is the asynchronous interface's default mode of operation. It is selected when the SS bit in the asynchronous *n* configuration register (CENCFG) is cleared to 0. In this mode, the EMIF\_nDQM pins operate as byte enables. [Section 17.2.6.4.1](#) and [Section 17.2.6.4.2](#) explain the details of read and write operations while in Normal Mode.

##### 17.2.6.4.1 Asynchronous Read Operations (Normal Mode)

**NOTE:** During an entire asynchronous read operation, the EMIF\_nWE pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in [Section 17.2.2](#) request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once it becomes the EMIF's highest priority task, according to the priority scheme detailed in [Section 17.2.13](#). In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles will be performed by the EMIF until the entire request is fulfilled. The details of an asynchronous read operation in Normal Mode are described in [Table 17-19](#). Also, [Figure 17-10](#) shows an example timing diagram of a basic read operation.

**Table 17-19. Asynchronous Read Operation in Normal Mode**

| Time Interval      | Pin Activity in Normal Mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Turn-around period | <p>Once the read operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous <i>n</i> configuration register (CENCFG). There are two exceptions to this rule:</p> <ul style="list-style-type: none"> <li>If the current read operation was directly preceded by another read operation, no turnaround cycles are inserted.</li> <li>If the current read operation was directly preceded by a write operation and the TA field has been cleared to 0, one turn-around cycle will be inserted.</li> </ul> <p>After the EMIF has waited for the turnaround cycles to complete, it again checks to make sure that the read operation is still its highest priority task. If so, the EMIF proceeds to the setup period of the operation. If it is no longer the highest priority task, the EMIF terminates the operation.</p> |

**Table 17-19. Asynchronous Read Operation in Normal Mode (continued)**

| Time Interval             | Pin Activity in Normal Mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Start of the setup period | <p>The following actions occur at the start of the setup period:</p> <ul style="list-style-type: none"> <li>The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in CEnCFG.</li> <li>The address pins EMIF_A and EMIF_BA become valid and carry the values described in <a href="#">Section 17.2.6.1</a>.</li> <li>EMIF_nCS[4:2] falls to enable the external device (if not already low from a previous operation)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Strobe period             | <p>The following actions occur during the strobe period of a read operation:</p> <ol style="list-style-type: none"> <li>EMIF_nOE falls at the start of the strobe period</li> <li>On the rising edge of the clock which is concurrent with the end of the strobe period: <ul style="list-style-type: none"> <li>EMIF_nOE rises</li> <li>The data on the EMIF_D bus is sampled by the EMIF.</li> </ul> </li> </ol> <p>In <a href="#">Figure 17-10</a>, EMIF_nWAIT is inactive. If EMIF_nWAIT is instead activated, the strobe period can be extended by the external device to give it more time to provide the data. <a href="#">Section 17.2.6.6</a> contains more details on using the EMIF_nWAIT pin.</p>                                                                                                                                                                                                               |
| End of the hold period    | <p>At the end of the hold period:</p> <ul style="list-style-type: none"> <li>The address pins EMIF_A and EMIF_BA become invalid</li> <li>EMIF_nCS[4:2] rises (if no more operations are required to complete the current request)</li> </ul> <p>EMIF may be required to issue additional read operations to a device with a small data bus width in order to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turn-round cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to its previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.</p> |

**Figure 17-10. Timing Waveform of an Asynchronous Read Cycle in Normal Mode**

### 17.2.6.4.2 Asynchronous Write Operations (Normal Mode)

**NOTE:** During an entire asynchronous write operation, the EMIF\_nOE pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in [Section 17.2.2](#) request a write to memory in the asynchronous bank of the EMIF. After the request is received, a write operation is initiated once it becomes the EMIF's highest priority task, according to the priority scheme detailed in [Section 17.2.13](#). In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles will be performed by the EMIF until the entire request is fulfilled. The details of an asynchronous write operation in Normal Mode are described in [Table 17-20](#). Also, [Figure 17-11](#) shows an example timing diagram of a basic write operation.

**Table 17-20. Asynchronous Write Operation in Normal Mode**

| Time Interval             | Pin Activity in Normal Mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Turnaround period         | <p>Once the write operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous <i>n</i> configuration register (CENCFG). There are two exceptions to this rule:</p> <ul style="list-style-type: none"> <li>If the current write operation was directly preceded by another write operation, no turn-around cycles are inserted.</li> <li>If the current write operation was directly preceded by a read operation and the TA field has been cleared to 0, one turnaround cycle will be inserted.</li> </ul> <p>After the EMIF has waited for the turn-around cycles to complete, it again checks to make sure that the write operation is still its highest priority task. If so, the EMIF proceeds to the setup period of the operation. If it is no longer the highest priority task, the EMIF terminates the operation.</p> |
| Start of the setup period | <p>The following actions occur at the start of the setup period:</p> <ul style="list-style-type: none"> <li>The setup, strobe, and hold values are set according to the W_SETUP, W_STROBE, and W_HOLD values in CENCFG.</li> <li>The address pins EMIF_A and EMIF_BA and the data pins EMIF_D become valid. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.</p>                                                 |

**Figure 17-11. Timing Waveform of an Asynchronous Write Cycle in Normal Mode**

### 17.2.6.5 Read and Write Operation in Select Strobe Mode

Select Strobe Mode is the EMIF's second mode of operation. It is selected when the SS bit of the asynchronous *n* configuration register (CENCFG) is set to 1. In this mode, the EMIF\_nDQM pins operate as byte enables and the EMIF\_nCS[n] (n = 2, 3, or 4) pin is only active during the strobe period of an access cycle. [Section 17.2.6.4.1](#) and [Section 17.2.6.4.2](#) explain the details of read and write operations while in Select Strobe Mode.

#### 17.2.6.5.1 Asynchronous Read Operations (Select Strobe Mode)

**NOTE:** During the entirety of an asynchronous read operation, the EMIF\_nWE pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in [Section 17.2.2](#) request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once it becomes the EMIF's highest priority task, according to the priority scheme detailed in [Section 17.2.13](#). In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles will be performed by the EMIF until the entire request is fulfilled. The details of an asynchronous read operation in Select Strobe Mode are described in [Table 17-21](#). Also, [Figure 17-12](#) shows an example timing diagram of a basic read operation.

**Table 17-21. Asynchronous Read Operation in Select Strobe Mode**

| Time Interval             | Pin Activity in Select Strobe Mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Turnaround period         | <p>Once the read operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous <i>n</i> configuration register (CENCFG). There are two exceptions to this rule:</p> <ul style="list-style-type: none"> <li>If the current read operation was directly preceded by another read operation, no turn-around cycles are inserted.</li> <li>If the current read operation was directly preceded by a write operation and the TA field has been cleared to 0, one turn-around cycle will be inserted.</li> </ul> <p>After the EMIF has waited for the turn-around cycles to complete, it again checks to make sure that the read operation is still its highest priority task. If so, the EMIF proceeds to the setup period of the operation. If it is no longer the highest priority task, the EMIF terminates the operation.</p> |
| Start of the setup period | <p>The following actions occur at the start of the setup period:</p> <ul style="list-style-type: none"> <li>The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in CENCFG.</li> <li>The address pins EMIF_A and EMIF_BA become valid and carry the values described in <a href="#">Section 17.2.6.1</a>.</li> <li>The EMIF_nDQM pins become valid as byte enables.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Strobe period             | <p>The following actions occur during the strobe period of a read operation:</p> <ol style="list-style-type: none"> <li>EMIF_nCS[n] (n = 2, 3, or 4) and EMIF_nOE fall at the start of the strobe period</li> <li>On the rising edge of the clock which is concurrent with the end of the strobe period: <ul style="list-style-type: none"> <li>EMIF_nCS[n] (n = 2, 3, or 4) and EMIF_nOE rise</li> <li>The data on the EMIF_D bus is sampled by the EMIF.</li> </ul> </li> </ol> <p>In <a href="#">Figure 17-12</a>, EMIF_nWAIT is inactive. If EMIF_nWAIT is instead activated, the strobe period can be extended by the external device to give it more time to provide the data. <a href="#">Section 17.2.6.6</a> contains more details on using the EMIF_nWAIT pin.</p>                                                                                                                                                                                                                                                      |
| End of the hold period    | <p>At the end of the hold period:</p> <ul style="list-style-type: none"> <li>The address pins EMIF_A and EMIF_BA become invalid</li> <li>The EMIF_nDQM pins become invalid</li> </ul> <p>The EMIF may be required to issue additional read operations to a device with a small data bus width in order to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to its previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.</p>                                                                                                                                                           |

**Figure 17-12. Timing Waveform of an Asynchronous Read Cycle in Select Strobe Mode**

### 17.2.6.5.2 Asynchronous Write Operations (Select Strobe Mode)

**NOTE:** During the entirety of an asynchronous write operation, the EMIF\_nOE pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in [Section 17.2.2](#) request a write to memory in the asynchronous bank of the EMIF. After the request is received, a write operation is initiated once it becomes the EMIF's highest priority task, according to the priority scheme detailed in [Section 17.2.13](#). In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles will be performed by the EMIF until the entire request is fulfilled. The details of an asynchronous write operation in Select Strobe Mode are described in [Table 17-22](#). Also, [Figure 17-13](#) shows an example timing diagram of a basic write operation.

**Table 17-22. Asynchronous Write Operation in Select Strobe Mode**

| Time Interval             | Pin Activity in Select Strobe Mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Turnaround period         | <p>Once the write operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turnaround cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous <i>n</i> configuration register (CENCFG). There are two exceptions to this rule:</p> <ul style="list-style-type: none"> <li>• If the current write operation was directly preceded by another write operation, no turn-around cycles are inserted.</li> <li>• If the current write operation was directly preceded by a read operation and the TA field has been cleared to 0, one turnaround cycle will be inserted.</li> </ul> <p>After the EMIF has waited for the turnaround cycles to complete, it again checks to make sure that the write operation is still its highest priority task. If so, the EMIF proceeds to the setup period of the operation. If it is no longer the highest priority task, the EMIF terminates the operation.</p> |
| Start of the setup period | <p>The following actions occur at the start of the setup period:</p> <ul style="list-style-type: none"> <li>• The setup, strobe, and hold values are set according to the W_SETUP, W_STROBE, and W_HOLD values in CENCFG.</li> <li>• The address pins EMIF_A and EMIF_BA and the data pins EMIF_D become valid. The EMIF_A and EMIF_BA pins carry the values described in <a href="#">Section 17.2.6.1</a>.</li> <li>• The EMIF_nDQM pins become active as byte enables.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Strobe period             | <p>The following actions occur at the start of the strobe period of a write operation:</p> <ul style="list-style-type: none"> <li>• EMIF_nCS[n] (n = 2, 3, or 4) and EMIF_nWE fall</li> </ul> <p>The following actions occur on the rising edge of the clock which is concurrent with the end of the strobe period:</p> <ul style="list-style-type: none"> <li>• EMIF_nCS[n] (n = 2, 3, or 4) and EMIF_nWE rise</li> </ul> <p>In <a href="#">Figure 17-13</a>, EMIF_nWAIT is inactive. If EMIF_nWAIT is instead activated, the strobe period can be extended by the external device to give it more time to accept the data. <a href="#">Section 17.2.6.6</a> contains more details on using the EMIF_nWAIT pin.</p>                                                                                                                                                                                                                                                                                                                   |
| End of the hold period    | <p>At the end of the hold period:</p> <ul style="list-style-type: none"> <li>• The address pins EMIF_A and EMIF_BA become invalid</li> <li>• The data pins become invalid</li> <li>• The EMIF_nDQM pins become invalid</li> </ul> <p>The EMIF may be required to issue additional write operations to a device with a small data bus width in order to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to its previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turn-around period for the pending read or write operation.</p>                                                                                                                  |

**Figure 17-13. Timing Waveform of an Asynchronous Write Cycle in Select Strobe Mode**

#### 17.2.6.6 Extended Wait Mode and the EMIF\_nWAIT Pin

The EMIF supports the Extend Wait Mode. This is a mode in which the external asynchronous device may assert control over the length of the strobe period. The Extended Wait Mode can be entered by setting the EW bit in the asynchronous  $n$  configuration register (CENCFG) ( $n = 2, 3$ , or  $4$ ). When this bit is set, the EMIF monitors the EMIF\_nWAIT pin to determine if the attached device wishes to extend the strobe period of the current access cycle beyond the programmed number of clock cycles.

When the EMIF detects that the EMIF\_nWAIT pin has been asserted, it will begin inserting extra strobe cycles into the operation until the EMIF\_nWAIT pin is deactivated by the external device. The EMIF will then return to the last cycle of the programmed strobe period and the operation will proceed as usual from this point. Please refer to the device data manual for details on the timing requirements of the EMIF\_nWAIT signal.

The EMIF\_nWAIT pin cannot be used to extend the strobe period indefinitely. The programmable MAX\_EXT\_WAIT field in the asynchronous wait cycle configuration register (AWCC) determines the maximum number of EMIF\_CLK cycles the strobe period may be extended beyond the programmed length. When the counter expires, the EMIF proceeds to the hold period of the operation regardless of the state of the EMIF\_nWAIT pin. The EMIF can also generate an interrupt upon expiration of this counter. See [Section 17.2.9.1](#) for details on enabling this interrupt.

For the EMIF to function properly in the Extended Wait mode, the WP $n$  bit of AWCC must be programmed to match the polarity of the EMIF\_nWAIT pin. In its reset state of 1, the EMIF will insert wait cycles when the EMIF\_nWAIT pin is sampled high. When set to 0, the EMIF will insert wait cycles only when EMIF\_nWAIT is sampled low. This programmability allows for a glueless connection to larger variety of asynchronous devices.

Finally, a restriction is placed on the strobe period timing parameters when operating in Extended Wait mode. Specifically, the sum of the W\_SETUP and W\_STROBE fields must be greater than 4, and the sum of the R\_SETUP and R\_STROBE fields must be greater than 4 for the EMIF to recognize the EMIF\_nWAIT pin has been asserted. The W\_SETUP, W\_STROBE, R\_SETUP, and R\_STROBE fields are in CENCFG.

### 17.2.6.7 NOR Flash Page Mode

EMIF supports Page mode reads for NOR Flash on its asynchronous memory chip selects. This mode can be enabled by writing a 1 to the  $CS_n\_PG\_MD\_EN$  ( $n = 2, 3, \text{ or } 4$ ) field in the Page Mode Control register for the chip select in consideration. Whenever Page Mode for reads is enabled for a particular chip select, the page size for the device connected must also be programmed in the  $CS_n\_PG\_SIZE$  field of the Page Mode Control register. The address change to valid read data available timing must be programmed in the  $CS_n\_PG\_DEL$  field of the Page Control register. All other asynchronous memory timings must be programmed in the asynchronous configuration register (CENCFG). See [Figure 17-14](#) for read in asynchronous page mode.

**NOTE:** The Extended Wait mode and the Select Strobe mode must be disabled when using the asynchronous interface in Page mode.

**Figure 17-14. Asynchronous Read in Page Mode**

### 17.2.7 Data Bus Parking

The EMIF always drives the data bus to the previous write data value when it is idle. This feature is called data bus parking. Only when the EMIF issues a read command to the external memory does it stop driving the data bus. After the EMIF latches the last read data, it immediately parks the data bus again.

The one exception to this behavior occurs after performing an asynchronous read operation while the EMIF is in the self-refresh state. In this situation, the read operation is not followed by the EMIF parking the data bus. Instead, the EMIF tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIF is in the self-refresh state, in order to prevent floating inputs on the data bus. External pull-ups, such as 10kΩ resistors, should be placed on the 16 EMIF data bus pins (which do not have internal pull-ups) if it is required to perform reads in this situation. The precise resistor value should be chosen so that the worst case combined off-state leakage currents do not cause the voltage levels on the associated pins to drop below the high-level input voltage requirement.

For information about the self-refresh state, see [Section 17.2.5.7](#).

## 17.2.8 Reset and Initialization Considerations

The EMIF memory controller has two active-low reset signals, `CHIP_RST_n` and `MOD_G_RST_n`. Both these reset signals are driven by the device system reset signal. This device does not offer the flexibility to reset just the EMIF state machine without also resetting the EMIF controller's memory-mapped registers. As soon as the device system reset is released (driven High), the EMIF memory controller immediately begins its initialization sequence. Command and data stored in the EMIF memory controller FIFOs are lost. Refer the Architecture chapter of the technical reference manual (TRM) for more information on conditions that can cause a device system reset to be asserted.

When system reset is released, the EMIF automatically begins running the SDRAM initialization sequence described in [Section 17.2.5.4](#). Even though the initialization procedure is automatic, a special procedure, found in [Section 17.2.5.5](#) must still be followed.

## 17.2.9 Interrupt Support

The EMIF supports a single interrupt to the CPU. [Section 17.2.9.1](#) details the generation and internal masking of EMIF interrupts.

### 17.2.9.1 Interrupt Events

There are three conditions that may cause the EMIF to generate an interrupt to the CPU. These conditions are:

- A rising edge on the `EMIF_nWAIT` signal (wait rise interrupt)
- An asynchronous time out
- Usage of unsupported addressing mode (line trap interrupt)

The wait rise interrupt occurs when a rising edge is detected on `EMIF_nWAIT` signal. This interrupt generation is not affected by the `WPn` bit in the asynchronous wait cycle configuration register (AWCC). The asynchronous time out interrupt condition occurs when the attached asynchronous device fails to deassert the `EMIF_nWAIT` pin within the number of cycles defined by the `MAX_EXT_WAIT` bit in AWCC (this happens only in extended wait mode). EMIF supports only linear incrementing and cache line wrap addressing modes. If an access request for an unsupported addressing mode is received, the EMIF will set the `LT` bit in the EMIF interrupt raw register (INTRAW) and treat the request as a linear incrementing request.

Only when the interrupt is enabled by setting the appropriate bit (`WR_MASK_SET/AT_MASK_SET/LT_MASK_SET`) in the EMIF interrupt mask set register (INTMSKSET) to 1, will the interrupt be sent to the CPU. Once enabled, the interrupt may be disabled by writing a 1 to the corresponding bit in the EMIF interrupt mask clear register (INTMSKCLR). The bit fields in both the INTMSKSET and INTMSKCLR may be used to indicate whether the interrupt is enabled. When the interrupt is enabled, the corresponding bit field in both the INTMSKSET and INTMSKCLR will have a value of 1; when the interrupt is disabled, the corresponding bit field will have a value of 0.

The EMIF interrupt raw register (INTRAW) and the EMIF interrupt mask register (INTMSK) indicate the status of each interrupt. The appropriate bit (`WR/AT/LT`) in INTRAW is set when the interrupt condition occurs, whether or not the interrupt has been enabled. However, the appropriate bit (`WR_MASKED/AT_MASKED/LT_MASKED`) in INTMSK is set only when the interrupt condition occurs and the interrupt is enabled. Writing a 1 to the bit in INTRAW clears the INTRAW bit as well as the corresponding bit in INTMSK. [Table 17-23](#) contains a brief summary of the interrupt status and control bit fields. See [Section 17.3](#) for complete details on the register fields.

**Table 17-23. Interrupt Monitor and Control Bit Fields**

| Register Name                                  | Bit Name    | Description                                                                                                                                                    |
|------------------------------------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EMIF interrupt raw register (INTRAW)           | WR          | This bit is set when an rising edge on the EMIF_nWAIT signal occurs. Writing a 1 clears the WR bit as well as the WR_MASKED bit in INTMSK.                     |
|                                                | AT          | This bit is set when an asynchronous timeout occurs. Writing a 1 clears the AT bit as well as the AT_MASKED bit in INTMSK.                                     |
|                                                | LT          | This bit is set when an unsupported addressing mode is used. Writing a 1 clears LT bit as well as the LT_MASKED bit in INTMSK.                                 |
| EMIF interrupt mask register (INTMSK)          | WR_MASKED   | This bit is set only when a rising edge on the EMIF_nWAIT signal occurs and the interrupt has been enabled by writing a 1 to the WR_MASK_SET bit in INTMSKSET. |
|                                                | AT_MASKED   | This bit is set only when an asynchronous timeout occurs and the interrupt has been enabled by writing a 1 to the AT_MASK_SET bit in INTMSKSET.                |
|                                                | LT_MASKED   | This bit is set only when line trap interrupt occurs and the interrupt has been enabled by writing a 1 to the LT_MASK_SET bit in INTMSKSET.                    |
| EMIF interrupt mask set register (INTMSKSET)   | WR_MASK_SET | Writing a 1 to this bit enables the wait rise interrupt.                                                                                                       |
|                                                | AT_MASK_SET | Writing a 1 to this bit enables the asynchronous timeout interrupt.                                                                                            |
|                                                | LT_MASK_SET | Writing a 1 to this bit enables the line trap interrupt.                                                                                                       |
| EMIF interrupt mask clear register (INTMSKCLR) | WR_MASK_CLR | Writing a 1 to this bit disables the wait rise interrupt.                                                                                                      |
|                                                | AT_MASK_CLR | Writing a 1 to this bit disables the asynchronous timeout interrupt.                                                                                           |
|                                                | LT_MASK_CLR | Writing a 1 to this bit disables the line trap interrupt.                                                                                                      |

### 17.2.10 DMA Event Support

EMIF memory controller is a DMA slave peripheral and therefore does not generate DMA events. Data read and write requests may be made directly, by masters and the DMA.

### 17.2.11 EMIF Signal Multiplexing

For details on EMIF signal multiplexing, see the I/O Multiplexing Module chapter of the technical reference manual.

### 17.2.12 Memory Map

For information describing the device memory-map, see your device-specific datasheet.

### 17.2.13 Priority and Arbitration

[Section 17.2.2](#) describes the external prioritization and arbitration among requests from different sources within the microcontroller. The result of this external arbitration is that only one request is presented to the EMIF at a time. Once the EMIF completes a request, the external arbiter then provides the EMIF with the next pending request.

Internally, the EMIF undertakes memory device transactions according to a strict priority scheme. The highest priority events are:

- A device reset.
- A write to any of the three least significant bytes of the SDRAM configuration register (SDCR).

Either of these events will cause the EMIF to immediately commence its initialization sequence as described in [Section 17.2.5.4](#).

Once the EMIF has completed its initialization sequence, it performs memory transactions according to the following priority scheme (highest priority listed first):

1. If the EMIF's backlog refresh counter is at the Refresh Must urgency level, the EMIF performs multiple SDRAM auto refresh cycles until the Refresh Release urgency level is reached.
2. If an SDRAM or asynchronous read has been requested, the EMIF performs a read operation.
3. If the EMIF's backlog refresh counter is at the Refresh Need urgency level, the EMIF performs an SDRAM auto refresh cycle.
4. If an SDRAM or asynchronous write has been requested, the EMIF performs a write operation.
5. If the EMIF's backlog refresh counter is at the Refresh May or Refresh Release urgency level, the EMIF performs an SDRAM auto refresh cycle.
6. If the value of the SR bit in SDCR has been set to 1, the EMIF will enter the self-refresh state as described in [Section 17.2.5.7](#).

After taking one of the actions listed above, the EMIF then returns to the top of the priority list to determine its next action.

Because the EMIF does not issue auto-refresh cycles when in the self-refresh state, the above priority scheme does not apply when in this state. See [Section 17.2.5.7](#) for details on the operation of the EMIF when in the self-refresh state.

## 17.2.14 System Considerations

This section describes various system considerations to keep in mind when operating the EMIF.

### 17.2.14.1 Asynchronous Request Times

In a system that interfaces to both SDRAM and asynchronous memory, the asynchronous requests must not take longer than the smaller of the following two values:

- $t_{RAS}$  (typically 120  $\mu$ s) - to avoid violating the maximum time allowed between issuing an ACTV and PRE command to the SDRAM.
- $t_{Refresh\ Rate} \times 11$  (typically 15.7  $\mu$ s  $\times$  11 = 172.7  $\mu$ s) - to avoid refresh violations on the SDRAM.

The length of an asynchronous request is controlled by multiple factors, the primary factor being the number of access cycles required to complete the request. For example, an asynchronous request for 4 bytes will require four access cycles using an 8-bit data bus and only two access cycle using a 16-bit data bus. The maximum request size that the EMIF can be sent is 16 words, therefore the maximum number of access cycles per memory request is 64 when the EMIF is configured with an 8-bit data bus. The length of the individual access cycles that make up the asynchronous request is determined by the programmed setup, strobe, hold, and turnaround values, but can also be extended with the assertion of the EMIF\_nWAIT input signal up to a programmed maximum limit. It is up to the user to make sure that an entire asynchronous request does not exceed the timing values listed above when also interfacing to an SDRAM device. This can be done by limiting the asynchronous timing parameters.

### 17.2.14.2 Interface to External Peripheral or FIFO Memory

If EMIF is used to interface to an external peripheral or FIFO logic (e.g. UHPI), it is recommended to use the host CPU's Memory Protection Unit (MPU) to define this external memory range as a region that is either strongly-ordered or of device type.

### 17.2.14.3 Interface to External SDRAM

If EMIF is used to interface to an external SDRAM, it is recommended to burst as much as possible to normal memory to improve the interface bandwidth.

### 17.2.15 Power Management

Power dissipation from the EMIF memory controller may be managed by following methods:

- Self-refresh mode
- Power-down mode
- Gating input clocks to the module off

Gating input clocks off to the EMIF memory controller achieves higher power savings when compared to the power savings of self-refresh or power down mode. The input clock VCLK3 can be turned off through the use of the Global Clock Module (GCM). Before gating clocks off, the EMIF memory controller must place the SDR SDRAM memory in self-refresh mode. If the external memory requires a continuous clock, the VCLK3 clock domain must not be turned off because this may result in data corruption. See the following subsections for the proper procedures to follow when stopping the EMIF memory controller clocks.

#### 17.2.15.1 Power Management Using Self-Refresh Mode

The EMIF can be placed into a self-refresh state in order to place the attached SDRAM devices into self-refresh mode, which consumes less power for most SDRAM devices. In this state, the attached SDRAM device uses an internal clock to perform its own auto refresh cycles. This maintains the validity of the data in the SDRAM without the need for any external commands. Refer to [Section 17.2.5.7](#) for more details on placing the EMIF into the self-refresh state.

#### 17.2.15.2 Power Management Using Power Down Mode

In the power down mode, EMIF drives EMIF\_CKE low to lower the power consumption. EMIF\_CKE goes high when there is a need to send refresh (REFR) commands, after which EMIF\_CKE is again driven low. EMIF\_CKE remains low until any request arrives. Refer to [Section 17.2.5.8](#) for more details on placing EMIF in power down mode.

### 17.2.16 Emulation Considerations

EMIF memory controller remains fully functional during emulation halts in order to allow emulation access to external memory.

## 17.3 Registers

The external memory interface (EMIF) is controlled by programming its internal memory-mapped registers (MMRs). [Table 17-24](#) lists the memory-mapped registers for the EMIF.

**NOTE:** All EMIF MMRs, except SDCR, support only word (32-bit) accesses. Performing a byte (8-bit) or halfword (16-bit) write to these registers results in undefined behavior. The SDCR is byte writable to allow the setting of the SR, PD and PDWR bits without triggering the SDRAM initialization sequence.

The EMIF registers must always be accessed using 32-bit accesses (unless otherwise specified in this chapter). The base address of the memory-mapped registers of EMIF is FCFF E800h.

**Table 17-24. External Memory Interface (EMIF) Registers**

| Offset | Acronym   | Register Description                           | Section                         |

### 17.3.1 Module ID Register (MIDR)

This is a read-only register indicating the module ID of the EMIF. The MIDR is shown in [Figure 17-15](#) and described in [Table 17-25](#).

**Figure 17-15. Module ID Register (MIDR) [offset = 00]**

| 31-0 | REV   | x     | Module ID of EMIF. See the device-specific data manual. |

### 17.3.2 Asynchronous Wait Cycle Configuration Register (AWCC)

The asynchronous wait cycle configuration register (AWCC) is used to configure the parameters for extended wait cycles. Both the polarity of the EMIF\_nWAIT pin(s) and the maximum allowable number of extended wait cycles can be configured. The AWCC is shown in Figure 17-16 and described in Table 17-26. Not all devices support both EMIF\_nWAIT[1] and EMIF\_nWAIT[0], see the device-specific data manual to determine support on each device.

**NOTE:** The EW bit in the asynchronous *n* configuration register (CE<sub>n</sub>CFG) must be set to allow for the insertion of extended wait cycles.

**Figure 17-16. Asynchronous Wait Cycle Configuration Register (AWCCR) [offset = 04h]**

This signal determines which EMIF_nWAIT[n] signal will be used for memory accesses to chip select 2 memory space.<br>EMIF_nWAIT[0] pin is used to control external wait states..<br>EMIF_nWAIT[1] pin is used to control external wait states.<br>Reserved |
| 15-8  | Reserved     | 0                        | Reserved                                                                                                                                                                                                                                                                                        |
| 7-0   | MAX_EXT_WAIT | 0-FFh                    | Maximum extended wait cycles. The EMIF will wait for a maximum of (MAX_EXT_WAIT + 1) × 16 clock cycles before it stops inserting asynchronous wait cycles and proceeds to the hold period of the access.                                                                                        |

### 17.3.3 SDRAM Configuration Register (SDCR)

The SDRAM configuration register (SDCR) is used to configure various parameters of the SDRAM controller such as the number of internal banks, the internal page size, and the CAS latency to match those of the attached SDRAM device. In addition, this register is used to put the attached SDRAM device into Self-Refresh mode. The SDCR is shown in [Figure 17-17](#) and described in [Table 17-27](#).

**NOTE:** Writing to the lower three bytes of this register will cause the EMIF to start the SDRAM initialization sequence described in [Section 17.2.5.4](#).

**Figure 17-17. SDRAM Configuration Register (SDCR) [offset = 08h]**

#### 17.3.4 SDRAM Refresh Control Register (SDRCR)

The SDRAM refresh control register (SDRCR) is used to configure the rate at which connected SDRAM devices will be automatically refreshed by the EMIF. Refer to [Section 17.2.5.6](#) on the refresh controller for more details. The SDRCR is shown in [Figure 17-18](#) and described in [Table 17-28](#).

**Figure 17-18. SDRAM Refresh Control Register (SDRCR) [offset = 0Ch]**

|          |    |          |    |
|----------|----|----------|----|
| 31       |    |          | 16 |
| Reserved |    |          |    |

### Table 17-28. SDRAM Refresh Control Register (SDRCR) Field Descriptions

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                    |
|-------|----------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0       | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                                                        |
| 12-0  | RR       | 0-1FFFh | Refresh Rate. This field is used to define the SDRAM refresh period in terms of EMIF_CLK cycles. Writing a value < 0x0020 to this field will cause it to be loaded with $(2 \times T\_RFC) + 1$ value from the SDRAM timing register (SDTIMR). |

### 17.3.5 Asynchronous *n* Configuration Registers (CE2CFG-CE5CFG)

The asynchronous *n* configuration registers (CE2CFG, CE3CFG, CE4CFG, and CE5CFG) are used to configure the shaping of the address and control signals during an access to asynchronous memory connected to CS2, CS3, CS4, and CS5, respectively. CS5 is not available on this device. It is also used to program the width of asynchronous Interfacend to select from various modes of operation. This register can be written prior to any transfer, and any asynchronous transfer following the write will use the new configuration. The CE $n$ CFG is shown in [Figure 17-19](#) and described in [Table 17-29](#).

**Figure 17-19. Asynchronous *n* Configuration Register (CE $n$ CFG) [offset = 10h - 1Ch]**

|                         |                         |         |        |                         |       |

**Table 17-30. SDRAM Timing Register (SDTIMR) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                   |
|-------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-27 | T_RFC    | 0-1Fh | Specifies the Trfc value of the SDRAM. This defines the minimum number of EMIF_CLK cycles from Refresh (REFR) to Refresh (REFR), minus 1:<br>$T\_RFC = (Trfc/t_{EMIF\_CLK}) - 1$                              |
| 26-24 | T_RP     | 0-7h  | Specifies the Trp value of the SDRAM. This defines the minimum number of EMIF_CLK cycles from Precharge (PRE) to Activate (ACTV) or Refresh (REFR) command, minus 1:<br>$T\_RP = (Trp/t_{EMIF\_CLK}) - 1$     |
| 23    | Reserved | 0     | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                       |
| 22-20 | T_RCD    | 0-7h  | Specifies the Trcd value of the SDRAM. This defines the minimum number of EMIF_CLK cycles from Active (ACTV) to Read (READ) or Write (WRT), minus 1:<br>$T\_RCD = (Trcd/t_{EMIF\_CLK}) - 1$                   |
| 19    | Reserved | 0     | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                       |
| 18-16 | T_WR     | 0-7h  | Specifies the Twr value of the SDRAM. This defines the minimum number of EMIF_CLK cycles from last Write (WRT) to Precharge (PRE), minus 1:<br>$T\_WR = (Twr/t_{EMIF\_CLK}) - 1$                              |
| 15-12 | T_RAS    | 0-Fh  | Specifies the Tras value of the SDRAM. This defines the minimum number of EMIF_CLK clock cycles from Activate (ACTV) to Precharge (PRE), minus 1:<br>$T\_RAS = (Tras/t_{EMIF\_CLK}) - 1$                      |
| 11-8  | T_RC     | 0-Fh  | Specifies the Trc value of the SDRAM. This defines the minimum number of EMIF_CLK clock cycles from Activate (ACTV) to Activate (ACTV), minus 1:<br>$T\_RC = (Trc/t_{EMIF\_CLK}) - 1$                         |
| 7     | Reserved | 0     | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                       |
| 6-4   | T_RRD    | 0-7h  | Specifies the Trrd value of the SDRAM. This defines the minimum number of EMIF_CLK clock cycles from Activate (ACTV) to Activate (ACTV) for a different bank, minus 1:<br>$T\_RRD = (Trrd/t_{EMIF\_CLK}) - 1$ |
| 3-0   | Reserved | 0     | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                       |

### 17.3.8 EMIF Interrupt Raw Register (INTRAW)

The EMIF interrupt raw register (INTRAW) is used to monitor and clear the EMIF's hardware-generated Asynchronous Timeout Interrupt. The AT bit in this register will be set when an Asynchronous Timeout occurs regardless of the status of the EMIF interrupt mask set register (INTMSKSET) and EMIF interrupt mask clear register (INTMSKCLR). Writing a 1 to this bit will clear it. The EMIF on some devices does not have the EMIF\_nWAIT pin; therefore, these registers and fields are reserved on those devices. The INTRAW is shown in [Figure 17-22](#) and described in [Table 17-32](#).

**Figure 17-22. EMIF Interrupt Raw Register (INTRAW) [offset = 40h]**

Writing a 1 will clear this bit as well as the LT_MASKED bit in the EMIF interrupt masked register (INTMSK).                                                                                                                                                                                                                                                                   |
| 0    | AT       | 0<br>1 | Asynchronous Timeout. This bit is set to 1 by hardware to indicate that during an extended asynchronous memory access cycle, the EMIF_nWAIT pin did not go inactive within the number of cycles defined by the MAX_EXT_WAIT field in the asynchronous wait cycle configuration register (AWCC).<br><br>0 Indicates that an Asynchronous Timeout has not occurred. Writing a 0 has no effect.<br>1 Indicates that an Asynchronous Timeout has occurred. Writing a 1 will clear this bit as well as the AT_MASKED bit in the EMIF interrupt masked register (INTMSK). |

### 17.3.9 EMIF Interrupt Masked Register (INTMSK)

Like the EMIF interrupt raw register (INTRAW), the EMIF interrupt masked register (INTMSK) is used to monitor and clear the status of the EMIF's hardware-generated Asynchronous Timeout Interrupt. The main difference between the two registers is that when the AT\_MASKED bit in this register is set, an active-high pulse will be sent to the CPU interrupt controller. Also, the AT\_MASKED bit field in INTMSK is only set to 1 if the associated interrupt has been enabled in the EMIF interrupt mask set register (INTMSKSET). The EMIF on some devices does not have the EMIF\_nWAIT pin, therefore, these registers and fields are reserved on those devices. The INTMSK is shown in Figure 17-23 and described in Table 17-33.

**Figure 17-23. EMIF Interrupt Mask Register (INTMSK) [offset = 44h]**

**Table 17-33. EMIF Interrupt Mask Register (INTMSK) Field Descriptions**

| Bit  | Field     | Value | Description                                                                                                                                                                                                                                                                                                                                                                                               |
|------|-----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved  | 0     | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                                                                                                                                                                                                                   |
| 2    | WR_MASKED | 0     | Wait Rise Masked. This bit is set to 1 by hardware to indicate a rising edge has occurred on the EMIF_nWAIT pin, provided that the WR_MASK_SET bit is set to 1 in the EMIF interrupt mask set register (INTMSKSET).                                                                                                                                                                                       |
|      |           | 1     | Indicates that a wait rise interrupt has not been generated. Writing a 0 has no effect.                                                                                                                                                                                                                                                                                                                   |
|      |           | 1     | Indicates that a wait rise interrupt has been generated. Writing a 1 will clear this bit and the WR bit in the EMIF interrupt raw register (INTRAW).                                                                                                                                                                                                                                                      |
| 1    | LT_MASKED | 0     | Masked Line Trap. Set to 1 by hardware to indicate illegal memory access type or invalid cache line size, only if the LT_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET) is set to 1.                                                                                                                                                                                                    |
|      |           | 1     | Writing a 0 has no effect.                                                                                                                                                                                                                                                                                                                                                                                |
|      |           | 1     | Writing a 1 will clear this bit as well as the LT bit in the EMIF interrupt raw register (INTRAW).                                                                                                                                                                                                                                                                                                        |
| 0    | AT_MASKED | 0     | Asynchronous Timeout Masked. This bit is set to 1 by hardware to indicate that during an extended asynchronous memory access cycle, the EMIF_nWAIT pin did not go inactive within the number of cycles defined by the MAX_EXT_WAIT field in the asynchronous wait cycle configuration register (AWCC), provided that the AT_MASK_SET bit is set to 1 in the EMIF interrupt mask set register (INTMSKSET). |
|      |           | 1     | Indicates that an Asynchronous Timeout Interrupt has not been generated. Writing a 0 has no effect.                                                                                                                                                                                                                                                                                                       |
|      |           | 1     | Indicates that an Asynchronous Timeout Interrupt has been generated. Writing a 1 will clear this bit as well as the AT bit in the EMIF interrupt raw register (INTRAW).                                                                                                                                                                                                                                   |

### 17.3.10 EMIF Interrupt Mask Set Register (INTMSKSET)

The EMIF interrupt mask set register (INTMSKSET) is used to enable the Asynchronous Timeout Interrupt. If read as 1, the AT\_MASKED bit in the EMIF interrupt masked register (INTMSK) will be set and an interrupt will be generated when an Asynchronous Timeout occurs. If read as 0, the AT\_MASKED bit will always read 0 and no interrupt will be generated when an Asynchronous Timeout occurs. Writing a 1 to the AT\_MASK\_SET bit enables the Asynchronous Timeout Interrupt. The EMIF on some devices does not have the EMIF\_nWAIT pin; therefore, these registers and fields are reserved on those devices. The INTMSKSET is shown in [Figure 17-24](#) and described in [Table 17-34](#).

Writing a 1 sets this bit and the LT_MASK_CLR bit in the EMIF interrupt mask clear register (INTMSKCLR).                                                                                                                                                                                                                                                                                                                                                           |
| 0    | AT_MASK_SET | 0<br>1 | Asynchronous Timeout Mask Set. This bit determines whether or not the Asynchronous Timeout Interrupt is enabled. Writing a 1 to this bit sets this bit, sets the AT_MASK_CLR bit in the EMIF interrupt mask clear register (INTMSKCLR), and enables the Asynchronous Timeout Interrupt. To clear this bit, a 1 must be written to the AT_MASK_CLR bit of the EMIF interrupt mask clear register (INTMSKCLR).<br><br>Indicates that the Asynchronous Timeout Interrupt is disabled. Writing a 0 has no effect.<br>Indicates that the Asynchronous Timeout Interrupt is enabled. Writing a 1 sets this bit and the AT_MASK_CLR bit in the EMIF interrupt mask clear register (INTMSKCLR). |

### 17.3.11 EMIF Interrupt Mask Clear Register (INTMSKCLR)

The EMIF interrupt mask clear register (INTMSKCLR) is used to disable the Asynchronous Timeout Interrupt. If read as 1, the AT\_MASKED bit in the EMIF interrupt masked register (INTMSK) will be set and an interrupt will be generated when an Asynchronous Timeout occurs. If read as 0, the AT\_MASKED bit will always read 0 and no interrupt will be generated when an Asynchronous Timeout occurs. Writing a 1 to the AT\_MASK\_CLR bit disables the Asynchronous Timeout Interrupt. The EMIF on some devices does not have the EMIF\_nWAIT pin, therefore, these registers and fields are reserved on those devices. The INTMSKCLR is shown in [Figure 17-25](#) and described in [Table 17-35](#).

| Bit  | Field       | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------|-------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved    | 0      | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 2    | WR_MASK_CLR | 0<br>1 | Wait Rise Mask Clear. This bit determines whether or not the wait rise interrupt is enabled. Writing a 1 to this bit clears this bit, clears the WR_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET), and disables the wait rise interrupt. To set this bit, a 1 must be written to the WR_MASK_SET bit in INTMSKSET.<br><br>0 Indicates that the wait rise interrupt is disabled. Writing a 0 has no effect.<br>1 Indicates that the wait rise interrupt is enabled. Writing a 1 clears this bit and the WR_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET).                                                                                               |
| 1    | LT_MASK_CLR | 0<br>1 | Line trap Mask Clear. This bit determines whether or not the line trap interrupt is enabled. Writing a 1 to this bit clears this bit, clears the LT_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET), and disables the line trap interrupt. To set this bit, a 1 must be written to the LT_MASK_SET bit in INTMSKSET.<br><br>0 Indicates that the line trap interrupt is disabled. Writing a 0 has no effect.<br>1 Indicates that the line trap interrupt is enabled. Writing a 1 clears this bit and the LT_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET).                                                                                               |
| 0    | AT_MASK_CLR | 0<br>1 | Asynchronous Timeout Mask Clear. This bit determines whether or not the Asynchronous Timeout Interrupt is enabled. Writing a 1 to this bit clears this bit, clears the AT_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET), and disables the Asynchronous Timeout Interrupt. To set this bit, a 1 must be written to the AT_MASK_SET bit of the EMIF interrupt mask set register (INTMSKSET).<br><br>0 Indicates that the Asynchronous Timeout Interrupt is disabled. Writing a 0 has no effect.<br>1 Indicates that the Asynchronous Timeout Interrupt is enabled. Writing a 1 clears this bit and the AT_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET). |

### 17.3.12 Page Mode Control Register (PMCR)

The page mode control register (PMCR) is shown in [Figure 17-26](#) and described in [Table 17-36](#). This register is configured when using NOR Flash page mode.

**Figure 17-26. Page Mode Control Register (PMCR) [offset = 68h]**

## 17.4 Example Configuration

This section presents an example of interfacing the EMIF to both an SDR SDRAM device and an asynchronous flash device.

### 17.4.1 Hardware Interface

Figure 17-27 shows the hardware interface between the EMIF, a Samsung K4S641632H-TC(L)70 64Mb SDRAM device, and two SHARP LH28F800BJE-PTTL90 8Mb Flash memory. The connection between the EMIF and the SDRAM is straightforward, but the connection between the EMIF and the flash deserves a detailed look.

The address inputs for the flash are provided by three sources. The A[18:0] address inputs are provided by a combination of the EMIF\_A and EMIF\_BA pins according to Section 17.2.6.1. RD/nBY signal from one flash is connected to EMIF\_nWAIT pin of EMIF.

Finally, this example configuration connects the EMIF\_nWE pin to the nWE input of the flash and operates the EMIF in Select Strobe Mode.

### 17.4.2 Software Configuration

The following sections describe how to configure the EMIF registers and bit fields to interface the EMIF with the Samsung K4S641632H-TC(L)70 SDRAM and the SHARP LH28F800BJE-PTTL90 8Mb Flash memory.

#### 17.4.2.1 Configuring the SDRAM Interface

This section describes how to configure the EMIF to interface with the Samsung K4S641632H-TC(L)70 SDRAM with a clock frequency of  $f_{\text{EMIF\_CLK}} = 100 \text{ MHz}$ . Procedure A described in Section 17.2.5.5 is followed which assumes that the SDRAM power-up timing constraint were met during the SDRAM Auto-Initialization sequence after Reset.

##### 17.4.2.1.1 PLL Programming for the EMIF to K4S641632H-TC(L)70 Interface

The device global clock module (GCM) should first be programmed to select the desired EMIF\_CLK frequency. Before doing this, the SDRAM should be placed in Self-Refresh Mode by setting the SR bit in the SDRAM configuration register (SDCR). The SR bit should be set using a byte-write to the upper byte of the SDCR to avoid triggering the SDRAM Initialization Sequence. The EMIF\_CLK frequency can now be configured to the desired value by selecting the appropriate clock source for the VCLK3 domain. Once the VCLK3 domain frequency has been configured, remove the SDRAM from Self-Refresh by clearing the SR bit in SDCR, again with a byte-write.

**Table 17-37. SR Field Value For the EMIF to K4S641632H-TC(L)70 Interface**

| Field | Value    | Purpose                                       |
|-------|----------|-----------------------------------------------|
| SR    | 1 then 0 | To place the EMIF into the self refresh state |

**Figure 17-27. Example Configuration Interface**

### 17.4.2.1.2 SDRAM Timing Register (SDTIMR) Settings for the EMIF to K4S641632H-TC(L)70 Interface

The fields of the SDRAM timing register (SDTIMR) should be programmed first as described in [Table 17-38](#) to satisfy the required timing parameters for the K4S641632H-TC(L)70. Based on these calculations, a value of 6111 4610h should be written to SDTIMR. [Figure 17-28](#) shows a graphical description of how SDTIMR should be programmed.

**Table 17-38. SDTIMR Field Calculations for the EMIF to K4S641632H-TC(L)70 Interface**

| Field Name | Formula                                          | Value from K4S641632H-TC(L)70 Datasheet               | Value Calculated for Field |
|------------|--------------------------------------------------|-------------------------------------------------------|----------------------------|
| T_RFC      | $T\_RFC \geq (t_{RFC} \times f_{EMIF\_CLK}) - 1$ | $t_{RC} = 68 \text{ ns (min)}^{(1)}$                  | 6                          |
| T_RP       | $T\_RP \geq (t_{RP} \times f_{EMIF\_CLK}) - 1$   | $t_{RP} = 20 \text{ ns (min)}$                        | 1                          |
| T_RCD      | $T\_RCD \geq (t_{RCD} \times f_{EMIF\_CLK}) - 1$ | $t_{RCD} = 20 \text{ ns (min)}$                       | 1                          |
| T_WR       | $T\_WR \geq (t_{WR} \times f_{EMIF\_CLK}) - 1$   | $t_{RDL} = 2 \text{ CLK} = 20 \text{ ns (min)}^{(2)}$ | 1                          |
| T_RAS      | $T\_RAS \geq (t_{RAS} \times f_{EMIF\_CLK}) - 1$ | $t_{RAS} = 49 \text{ ns (min)}$                       | 4                          |
| T_RC       | $T\_RC \geq (t_{RC} \times f_{EMIF\_CLK}) - 1$   | $t_{RC} = 68 \text{ ns (min)}$                        | 6                          |
| T_RRD      | $T\_RRD \geq (t_{RRD} \times f_{EMIF\_CLK}) - 1$ | $t_{RRD} = 14 \text{ ns (min)}$                       | 1                          |

<sup>(1)</sup> The Samsung datasheet does not specify a  $t_{RFC}$  value. Instead, Samsung specifies  $t_{RC}$  as the minimum auto refresh period.

<sup>(2)</sup> The Samsung datasheet does not specify a  $t_{WR}$  value. Instead, Samsung specifies  $t_{RDL}$  as last data in to row precharge minimum delay.

#### 17.4.2.1.3 SDRAM Self Refresh Exit Timing Register (SDSRETR) Settings for the EMIF to K4S641632H-TC(L)70 Interface

The SDRAM self refresh exit timing register (SDSRETR) should be programmed second to satisfy the  $t_{XSR}$  timing requirement from the K4S641632H-TC(L)70 datasheet. [Table 17-39](#) shows the calculation of the proper value to program into the T\_XS field of this register. Based on this calculation, a value of 6h should be written to SDSRETR. [Figure 17-29](#) shows how SDSRETR should be programmed.

**Table 17-39. RR Calculation for the EMIF to K4S641632H-TC(L)70 Interface**

| Field Name | Formula                                          | Value from K4S641632H-TC(L)70 Datasheet | Value Calculated for Field |
|------------|--------------------------------------------------|-----------------------------------------|----------------------------|
| T_XS       | $T_{XS} \geq (t_{XSR} \times f_{EMIF\_CLK}) - 1$ | $t_{RC} = 68 \text{ ns (min)}^{(1)}$    | 6                          |

<sup>(1)</sup> The Samsung datasheet does not specify a  $t_{XSR}$  value. Instead, Samsung specifies  $t_{RC}$  as the minimum required time after CKE going high to complete self refresh exit.

**Figure 17-29. SDRAM Self Refresh Exit Timing Register (SDSRETR)**

|                     |  |  |  |  |  |  |  |  |        |   |    |  |   |

#### 17.4.2.1.4 SDRAM Refresh Control Register (SDRCR) Settings for the EMIF to K4S641632H-TC(L)70 Interface

The SDRAM refresh control register (SDRCR) should next be programmed to satisfy the required refresh rate of the K4S641632H-TC(L)70. [Table 17-40](#) shows the calculation of the proper value to program into the RR field of this register. Based on this calculation, a value of 61Ah should be written to SDRCR. [Figure 17-30](#) shows how SDRCR should be programmed.

**Table 17-40. RR Calculation for the EMIF to K4S641632H-TC(L)70 Interface**

| Field Name | Formula                                                         | Values                                                                                                                 | Value Calculated for Field     |
|------------|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| RR         | $RR \leq f_{EMIF\_CLK} \times t_{Refresh\ Period} / n_{cycles}$ | From SDRAM datasheet: $t_{Refresh\ Period} = 64\ ms$ ; $n_{cycles} = 4096$ EMIF clock rate: $f_{EMIF\_CLK} = 100\ MHz$ | RR = 1562 cycles = 61Ah cycles |

**Figure 17-30. SDRAM Refresh Control Register (SDRCR)**

|                  |    |                         |          |  |    |
|------------------|----|-------------------------|----------|--|----|
| 31               | 19 |                         | 18       |  | 16 |

### 17.4.2.1.5 SDRAM Configuration Register (SDCR) Settings for the EMIF to K4S641632H-TC(L)70 Interface

Finally, the fields of the SDRAM configuration register (SDCR) should be programmed as described in [Table 17-37](#) to properly interface with the K4S641632H-TC(L)70 device. Based on these settings, a value of 4720h should be written to SDCR. [Figure 17-31](#) shows how SDCR should be programmed. The EMIF is now ready to perform read and write accesses to the SDRAM.

**Table 17-41. SDCR Field Values For the EMIF to K4S641632H-TC(L)70 Interface**

| Field       | Value | Purpose                                               |
|-------------|-------|-------------------------------------------------------|

### 17.4.2.2 Configuring the Flash Interface

This section describes how to configure the EMIF to interface with the two of SHARP LH28F800BJE-PTTL90 8Mb Flash memory with a clock frequency of  $f_{\text{EMIF\_CLK}} = 100 \text{ MHz}$ . The example assumes that one flash is connected to EMIF\_nCS2 and the other to EMIF\_nCS3.

#### 17.4.2.2.1 Asynchronous 1 Configuration Register (CE2CFG) Settings for the EMIF to LH28F800BJE-PTTL90 Interface

The asynchronous 1 configuration register (CE2CFG) and asynchronous 2 configuration register (CE3CFG) are the only registers that is necessary to program for this asynchronous interface (assuming that one Flash is connected to EMIF\_nCS[2] and the other to EMIF\_nCS[3]. The SS bit (in both registers) should be set to 1 to enable Select Strobe Mode and the ASIZE field (in both registers) should be set to 1 to select a 16-bit interface. The other fields in this register control the shaping of the EMIF signals, and the proper values can be determined by referring to the AC Characteristics in the Flash datasheet and the device datasheet. Based on the following calculations, a value of 8862 25BDh should be written to CE2CFG. [Table 17-42](#) and [Table 17-43](#) show the pertinent AC Characteristics for reads and writes to the Flash device, and [Figure 17-32](#) and [Figure 17-33](#) show the associated timing waveforms. Finally, [Figure 17-34](#) shows programming the CE $n$ CFG ( $n = 2, 3$ ) with the calculated values.

**Table 17-42. AC Characteristics for a Read Access**

| AC Characteristic | Device | Definition                                              | Min | Max | Unit |
|-------------------|--------|---------------------------------------------------------|-----|-----|------|
| $t_{\text{SU}}$   | EMIF   | Setup time, read EMIF_D before EMIF_CLK high            | 6.5 |     | ns   |
| $t_{\text{H}}$    | EMIF   | Data hold time, read EMIF_D after EMIF_CLK high         | 1   |     | ns   |
| $t_{\text{D}}$    | EMIF   | Output delay time, EMIF_CLK high to output signal valid |     | 7   | ns   |
| $t_{\text{ELQV}}$ | Flash  | nCE to Output Delay                                     |     | 90  | ns   |
| $t_{\text{EHQZ}}$ | Flash  | nCE High to Output in High Impedance                    |     | 55  | ns   |

**Table 17-43. AC Characteristics for a Write Access**

| AC Characteristic | Device | Definition                                                        | Min | Max | Unit |
|-------------------|--------|-------------------------------------------------------------------|-----|-----|------|
| $t_{\text{AVAV}}$ | Flash  | Write Cycle Time                                                  | 90  |     | ns   |
| $t_{\text{ELEH}}$ | Flash  | nCE Pulse Width Low                                               | 50  |     | ns   |
| $t_{\text{EHEL}}$ | Flash  | nCE Pulse Width High (not shown in <a href="#">Figure 17-33</a> ) | 30  |     | ns   |

**Figure 17-32. LH28F800BJE-PTTL90 to EMIF Read Timing Waveforms**

**Figure 17-33. LH28F800BJE-PTTL90 to EMIF Write Timing Waveforms**

The R\_STROBE field should be set to meet the following equation:

$$R\_STROBE \geq (t_D + t_{ELQV} + t_{SU}) \times f_{EMIF\_CLK} - 1$$

$$R\_STROBE \geq (7 \text{ ns} + 90 \text{ ns} + 6.5 \text{ ns}) \times 100 \text{ MHz} - 1$$

$$R\_STROBE \geq 9.35$$

$$R\_STROBE = 10$$

The R\_HOLD field must be large enough to satisfy the EMIF Data hold time,  $t_H$ :

$$R\_HOLD \geq t_H \times f_{EMIF\_CLK} - 1$$

$$R\_HOLD \geq 1 \text{ ns} \times 100 \text{ MHz} - 1$$

$$R\_HOLD \geq -0.9$$

The R\_HOLD field must also combine with the TA field to satisfy the Flash's nCE High to Output in High Impedance time,  $t_{EHQZ}$ :

$$R\_HOLD + TA \geq (t_D + t_{EHQZ}) \times f_{EMIF\_CLK} - 2$$

$$R\_HOLD + TA \geq (7 \text{ ns} + 55 \text{ ns}) \times 100 \text{ MHz} - 2$$

$$R\_HOLD + TA \geq 4.2$$

The largest value that can be programmed into the TA field is 3h, therefore the following values can be used:

$$R\_HOLD = 2$$

$$TA = 3$$

For Writes, the W\_STROBE field should be set to satisfy the Flash's nCE Pulse Width constraint,  $t_{ELEH}$ :

$$W\_STROBE \geq t_{ELEH} \times f_{EMIF\_CLK} - 1$$

$$W\_STROBE \geq 50 \text{ ns} \times 100 \text{ MHz} - 1$$

$$W\_STROBE \geq 4$$

The W\_SETUP and W\_HOLD fields should combine to satisfy the Flash's nCE Pulse Width High constraint,  $t_{EHEL}$ , when performing back-to-back writes:

$$W\_SETUP + W\_HOLD \geq t_{EHEL} \times f_{EMIF\_CLK} - 2$$

$$W\_SETUP + W\_HOLD \geq 30 \text{ ns} \times 100 \text{ MHz} - 2$$

$$W\_SETUP + W\_HOLD \geq 1$$

In addition, the entire Write access length must satisfy the Flash's minimum Write Cycle Time,  $t_{AVAV}$ :

$$W\_SETUP + W\_STROBE + W\_HOLD \geq t_{AVAV} \times f_{EMIF\_CLK} - 3$$

$$W\_SETUP + W\_STROBE + W\_HOLD \geq 90 \text{ ns} \times 100 \text{ MHz} - 3$$

$$W\_SETUP + W\_STROBE + W\_HOLD \geq 6$$

Solving the above equations for the Write fields results in the following possible solution:

$$W\_SETUP = 1$$

$$W\_STROBE = 5$$

$$W\_HOLD = 0$$

Adding a 10 ns (1 cycle) margin to each of the periods (excluding TA which is already at its maximum) in this example produces the following recommended values:

$$W\_SETUP = 2h$$

$$W\_STROBE = 6h$$

$$W\_HOLD = 1h$$

$$R\_SETUP = 1h$$

$$R\_STROBE = 8h$$

$$R\_HOLD = 3h$$

$$TA = 3h$$

## ***Parameter Overlay Module (POM)***

---

---

This chapter describes the parameter overlay module (POM).

| <b>Topic</b>                        | <b>Page</b> |
|-------------------------------------|-------------|
| <b>18.1 Introduction .....</b>      | <b>677</b>  |
| <b>18.2 Module Operation .....</b>  | <b>678</b>  |
| <b>18.3 Control Registers .....</b> | <b>679</b>  |

## 18.1 Introduction

In many applications it is important to be able to change certain parameters in the program without having to re-flash the device and immediately test these changes either in a hardware-in-the-loop simulation or in a real environment.

The POM provides a mechanism to redirect accesses to non-volatile memory into a volatile memory internal or external to the device. The data requested by the CPU will be fetched from the overlay memory instead of the main non-volatile memory. The overlay memory can be accessed directly by other masters in the system to provide an easy update path of the stored data. Other masters can be for example the main CPU, DMA, or JTAG.

### 18.1.1 Main Features

- Redirects program memory accesses to internal or external memory (overlay memory)
- Up to 8 MByte of external overlay memory
- Provides up to 32 programmable memory regions to replace non-volatile memory
  - Programmable region start address
  - Programmable region size (64 Bytes up to 256kBytes in power of 2 steps)

### 18.1.2 Block Diagram

**Figure 18-1. System Overlay Block Diagram**

## 18.2 Module Operation

The POM has up to 32 programmable regions. Whenever the CPU requests data from the non-volatile memory which address falls into one of the programmed regions, the POM will request the data from the overlay memory. Wait states will be automatically inserted until the data is available from the overlay memory. This ensures that the overlay memory has the same (in the case that the latency from overlay memory is less than the program memory latency) or slower access time than the program memory.

The POM does not provide a feature to write into the overlay memory. The write has to be performed directly to the memory mapped address space of the overlay memory.

When the module is disabled, no redirection of access will be performed.

---

**NOTE:** The overlay feature is not available for any other bus masters other than the main CPU. Any attempt to access overlaid memory via the POM by any other bus master would result in a deadlock situation (system hang). Other bus masters need to access the target internal or external memory directly.

---

### 18.2.1 Decode Regions

There are 32 decode regions. Regions are defined by a start address and a region size. The start address is 23 bits wide to cover the maximum 8 MByte address space defined for program memory. The region size ranges from 64 Bytes to 256 kBytes with a step size of power of 2. If a region size of 0 is selected, the region is disabled. To support overlay memory which has not the same size as the program memory, an overlay start address which is 23 bits wide, can be specified. The size of the overlay region is the same as the program memory region. The start address of both program memory and overlay memory region have to be a multiple of the programmed region size. When the address of the access falls into one of the programmed regions, the POM will start requesting the data from the overlay memory address, based on the overlay start address. If the address falls into multiple overlapping regions, the region with the lowest number has highest priority and only one read request from overlay memory will be initiated. This avoids that regions with the same program memory address, but different overlay memory addresses, request different data.

**Figure 18-2. Region Definition Example**

### 18.2.2 Bus Errors on Accesses via POM

In case a read by the POM cannot be completed within 32 HCLK cycles due to other transactions ongoing or due to other bus errors, a timeout mechanism is implemented. This timeout mechanism is disabled by default and must be enabled by writing 0xA to the "Enable Timeout" (ETO) field of the POM global control register (POMGLBCTRL, address = 0xFFA04000).

An abort is generated to the host CPU when this timeout occurs. The host CPU responds by either taking the prefetch abort or the data abort exceptions depending on the nature of the access that caused the timeout.

The abort handler can check if the TO flag is set in the POM module's flag register (POMFLG, address = 0xFFA0400C). If this flag is set, then the application can assume that the timeout is caused by the POM access not completing. This flag must be cleared so that any further aborts are not misinterpreted as having been caused by timeout on a POM access.

## 18.3 Control Registers

[Table 18-1](#) lists the Parameter Overlay Module registers. The registers support only 32-bit writes. The offset is relative to the associated peripheral select.

**Table 18-1. POM Registers**

| Address                   | Acronym          | Register Description                        | Section                         |
|---------------------------|------------------|---------------------------------------------|---------------------------------|

| Reserved |  |  |              |
| R-0      |  |  |              |
| 15       |  |  | 0            |
| Reserved |  |  | CLK GATE OFF |
| R-0      |  |  | R/W-0        |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

### Table 18-4. POM Clock Gate Control Register (POMCLKCTRL) Field Descriptions

| Bit  | Field        | Value | Description                                                                                                                                          |
|------|--------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-1 | Reserved     | 0     | Read returns 0. Writes have no effect.                                                                                                               |
| 0    | CLK GATE OFF | 0     | <b>Do not modify this bit. Leave it in its reset state. Modifying the bit while the POM module is switched on can result in unexpected behavior.</b> |

### 18.3.4 POM Status Register (POMFLG)

This register provides POM status information.

**Figure 18-6. POM Status Register [address = FFA0400Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 18-5. POM Status Register (POMFLG) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                      |
|------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-1 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                           |
| 0    | TO       | 0     | <b>Timeout.</b><br>This flag signals a timeout condition on the last CPU read access through the POM. This flag is only updated when the POM module is enabled (ON/OFF = Ah).<br>No timeout occurred. Writing a 0 has no effect. |
|      |          | 1     | Timeout occurred. This flag can be cleared by writing a 1 to it.                                                                                                                                                                 |

### 18.3.5 POM Program Region Start Address Register x (POMPROGSTARTx)

This register contains the start address of the region in program memory. x goes from 0 to 31, since up to 32 regions can be defined.

**Figure 18-7. POM Program Region Start Register x (POMPROGSTARTx) [address = FFA04200h, FFA04210h, ..., FFA043F0h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 18-6. POM Program Region Start Address Register x (POMPROGSTARTx) Field Descriptions**

| Bit   | Field        | Value | Description                                                                                                               |
|-------|--------------|-------|---------------------------------------------------------------------------------------------------------------------------|
| 31-23 | Reserved     | 0     | Read returns 0. Writes have no effect.                                                                                    |
| 22-0  | STARTADDRESS |       | <b>Defines the start address of the program memory region. The start address has to be a multiple of the region size.</b> |

**NOTE:** If the region start address is programmed to a non-region size boundary, the region will begin at the next lower region size boundary.

### 18.3.6 POM Overlay Region Start Address Register x (POMOVLSTARTx)

This register contains the start address of the region in overlay memory. x goes from 0 to 31, since up to 32 regions can be defined.

**Figure 18-8. POM Overlay Region Start Register x (POMOVLSTARTx) [address = FFA04204h, FFA04214h, ..., FFA043F4h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 18-7. POM Overlay Region Start Address Register x (POMOVLSTARTx) Field Descriptions**

| Bit   | Field        | Value | Description                                                                                                               |
|-------|--------------|-------|---------------------------------------------------------------------------------------------------------------------------|
| 31-23 | Reserved     | 0     | Read returns 0. Writes have no effect.                                                                                    |
| 22-0  | STARTADDRESS |       | <b>Defines the start address of the overlay memory region. The start address has to be a multiple of the region size.</b> |

**NOTE:** If the region start address is programmed to a non-region size boundary, the region will begin at the next lower region size boundary.

### 18.3.7 POM Region Size Register x (POMREGSIZEEx)

This register contains the region size for both program memory and overlay memory. x goes from 0 to 31, since up to 32 regions can be defined.

**Figure 18-9. POM Region Size Register x (POMREGSIZEEx) [address = FFA04208h, FFA04218h, ..., FFA043F8h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 18-8. POM Region Size Register x (POMREGSIZEEx) Field Descriptions**

| Bit  | Field    | Value | Description                            |
|------|----------|-------|----------------------------------------|
| 31-4 | Reserved | 0     | Read returns 0. Writes have no effect. |
| 3-0  | SIZE     |       | <b>Region size</b>                     |
|      |          | 0     | Region disabled                        |
|      |          | 1h    | 64 Bytes                               |
|      |          | 2h    | 128 Bytes                              |
|      |          | Dh    | 256 kBytes                             |
|      |          | Eh-Fh | Reserved                               |

**NOTE:** If the region is enabled by writing a non-zero value to the SIZE bitfield, it will take some number of VCLK cycles until the write takes effect. If during this time an access to the programmed region is taking place and the POM is already enabled in the POMGLBCTRL register, it either decodes the previous setting of the SIZE field or the access will be directed to the program memory when the region was disabled.

### 18.3.8 POM Integration Control Register (POMITCTRL)

This is a CoreSight register and is for debug purpose only. The integration functionality is not implemented. The register reads 00000000.

**Figure 18-10. POM Integration Control Register (POMITCTRL) [address = FFA04F00h]**

LEGEND: R = Read only; -n = value after reset

**Table 18-9. POM Integration Control Register (POMITCTRL) Field Descriptions**

| Bit  | Field    | Value | Description                            |
|------|----------|-------|----------------------------------------|
| 31-0 | Reserved | 0     | Read returns 0. Writes have no effect. |

### 18.3.9 POM Claim Set Register (POMCLAIMSET)

This is a CoreSight register and is for debug purpose only. This register allows different masters to claim the control for the POM module. There is no control functionality for POM register accesses implemented. The only functionality of these bits is to indicate that another master is controlling the module.

**Figure 18-11. POM Claim Set Register (POMCLAIMSET) [address = FFA04FA0h]**

|     |          |  |  |  |  |  |  |  |  |  |  |  |  |       |   |       |    |
|-----|----------|--|--|--|--|--|--|--|--|--|--|--|--|-------|---|-------|----|

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 18-10. POM Claim Set Register (POMCLAIMSET) Field Descriptions**

| Bit  | Field    | Value | Description                                                                              |
|------|----------|-------|------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Read returns 0. Writes have no effect.                                                   |
| 1    | SET1     | 0     | The module is claimed<br>Read: This claim tag bit is not implemented<br>Write: no effect |
|      |          | 1     | Read: This claim tag is implemented<br>Write: Set claim tag                              |
| 0    | SET0     | 0     | The module is claimed<br>Read: This claim tag bit is not implemented<br>Write: no effect |
|      |          | 1     | Read: This claim tag is implemented<br>Write: Set claim tag                              |

### 18.3.10 POM Claim Clear Register (POMCLAIMCLR)

This is a CoreSight register and is for debug purpose only. This register allows different masters to claim the control for the POM module. There is no control functionality for POM register accesses implemented. The only functionality of these bits is to indicate that another master is controlling the module.

**Figure 18-12. POM Claim Clear Register (POMCLAIMCLR) [address = FFA04FA4h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 18-11. POM Claim Clear Register (POMCLAIMCLR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                |
|------|----------|-------|----------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Read returns 0. Writes have no effect.                                     |
| 1    | CLR1     | 0     | The module is claimed<br>Read: Current claim tag value<br>Write: no effect |
|      |          | 1     | Write: Clear claim tag                                                     |
| 0    | CLR0     | 0     | The module is claimed<br>Read: Current claim tag value<br>Write: no effect |
|      |          | 1     | Write: Clear claim tag                                                     |

### 18.3.11 POM Lock Access Register (POMLOCKACCESS)

This is a CoreSight register and is for debug purpose only. The register reads 00000000.

**Figure 18-13. POM Lock Access Register (POMLOCKACCESS) [address = FFA04FB0h]**

LEGEND: R = Read only; -n = value after reset

**Table 18-12. POM Lock Access Register (POMLOCKACCESS) Field Descriptions**

| Bit  | Field    | Value | Description                            |
|------|----------|-------|----------------------------------------|
| 31-0 | Reserved | 0     | Read returns 0. Writes have no effect. |

### 18.3.12 POM Lock Status Register (POMLOCKSTATUS)

This is a CoreSight register and is for debug purpose only. The register reads 00000000.

**Figure 18-14. POM Lock Status Register (POMLOCKSTATUS) [address = FFA04FB4h]**

LEGEND: R = Read only; -n = value after reset

**Table 18-13. POM Lock Status Register (POMLOCKSTATUS) Field Descriptions**

| Bit  | Field    | Value | Description                            |
|------|----------|-------|----------------------------------------|
| 31-0 | Reserved | 0     | Read returns 0. Writes have no effect. |

### 18.3.13 POM Authentication Status Register (POMAUTHSTATUS)

This is a CoreSight register and is for debug purpose only. The register reads 00000000.

**Figure 18-15. POM Authentication Status Register (POMAUTHSTATUS) [address = FFA04FB8h]**

LEGEND: R = Read only; -n = value after reset

**Table 18-14. POM Authentication Status Register (POMAUTHSTATUS) Field Descriptions**

| Bit  | Field    | Value | Description                            |
|------|----------|-------|----------------------------------------|
| 31-0 | Reserved | 0     | Read returns 0. Writes have no effect. |

### 18.3.14 POM Device ID Register (POMDEVID)

This is a CoreSight register and is for debug purpose only. The register reads 00000000.

**Figure 18-16. POM Device ID Register (POMDEVID) [address = FFA04FC8h]**

LEGEND: R = Read only; -n = value after reset

**Table 18-15. POM Device ID Register (POMDEVID) Field Descriptions**

| Bit  | Field    | Value | Description                            |
|------|----------|-------|----------------------------------------|
| 31-0 | Reserved | 0     | Read returns 0. Writes have no effect. |

### 18.3.15 POM Device Type Register (POMDEVTYPE)

This is a CoreSight register and is for debug purpose only. The device type register defines the CoreSight module class.

**Figure 18-17. POM Device Type Register (POMDEVTYPE) [address = FFA04FCCh]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 18-16. POM Device Type Register (POMDEVTYPE) Field Descriptions**

| Bit  | Field      | Value | Description                            |
|------|------------|-------|----------------------------------------|
| 31-8 | Reserved   | 0     | Read returns 0. Writes have no effect. |
| 7-4  | Sub Type   | 0     | Other                                  |
| 3-0  | Major Type | 4h    | Debug Control                          |

### 18.3.16 POM Peripheral ID 4 Register (POMPERIPHERALID4)

This is a CoreSight register and is for debug purpose only. This register shows the peripheral identification of the CoreSight component.

**Figure 18-18. POM Peripheral ID 4 Register (POMPERIPHERALID4) [address = FFA04FD0h]**

|          |  |  |  |  |  |  |  |           |   |  |  |  |   |                          |  |    |  |   |  |
|----------|--|--|--|--|--|--|--|-----------|---|--|--|--|---|--------------------------|--|----|--|---|--|
| 31       |  |  |  |  |  |  |  |           |   |  |  |  |   |                          |  | 16 |  |   |  |
| Reserved |  |  |  |  |  |  |  |           |   |  |  |  |   |                          |  |    |  |   |  |
| R-0      |  |  |  |  |  |  |  |           |   |  |  |  |   |                          |  |    |  |   |  |
| 15       |  |  |  |  |  |  |  | 8         | 7 |  |  |  | 4 | 3                        |  |    |  | 0 |  |

| R-0      |  |  |  |  |  |  |  | R-0       |   |  |  |  |   | R-0                      |  |    |  |   |  |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 18-17. POM Peripheral ID 4 Register (POMPERIPHERALID4) Field Descriptions**

| Bit  | Field                 | Value | Description                            |
|------|-----------------------|-------|----------------------------------------|
| 31-8 | Reserved              | 0     | Read returns 0. Writes have no effect. |
| 7-4  | 4KB Count             | 0     | Only 4KB implemented                   |
| 3-0  | JEP Continuation Code | 0     | JEP106 Code                            |

### 18.3.17 POM Peripheral ID 5 Register (POMPERIPHERALID5)

This is a CoreSight register and is for debug purpose only. This register reads 00000000.

**Figure 18-19. POM Peripheral ID 5 Register (POMPERIPHERALID5) [address = FFA04FD4h]**

|          |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |   |
|----------|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|---|
| 31       |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0 |
| Reserved |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |   |
| R-0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |   |

LEGEND: R = Read only; -n = value after reset

**Table 18-18. POM Peripheral ID 5 Register (POMPERIPHERALID5) Field Descriptions**

| Bit  | Field    | Value | Description                            |
|------|----------|-------|----------------------------------------|
| 31-0 | Reserved | 0     | Read returns 0. Writes have no effect. |

### 18.3.18 POM Peripheral ID 6 Register (POMPERIPHERALID6)

This is a CoreSight register and is for debug purpose only. This register reads 00000000.

**Figure 18-20. POM Peripheral ID 6 Register (POMPERIPHERALID6) [address = FFA04FD8h]**

LEGEND: R = Read only; -n = value after reset

**Table 18-19. POM Peripheral ID 6 Register (POMPERIPHERALID6) Field Descriptions**

| Bit  | Field    | Value | Description                            |
|------|----------|-------|----------------------------------------|
| 31-0 | Reserved | 0     | Read returns 0. Writes have no effect. |

### 18.3.19 POM Peripheral ID 7 Register (POMPERIPHERALID7)

This is a CoreSight register and is for debug purpose only. This register reads 00000000.

**Figure 18-21. POM Peripheral ID 7 Register (POMPERIPHERALID7) [address = FFA04FDCh]**

LEGEND: R = Read only; -n = value after reset

**Table 18-20. POM Peripheral ID 7 Register (POMPERIPHERALID7) Field Descriptions**

| Bit  | Field    | Value | Description                            |
|------|----------|-------|----------------------------------------|
| 31-0 | Reserved | 0     | Read returns 0. Writes have no effect. |

### 18.3.20 POM Peripheral ID 0 Register (POMPERIPHERALID0)

This is a CoreSight register and is for debug purpose only. This register shows the peripheral identification of the CoreSight component.

**Figure 18-22. POM Peripheral ID 0 Register (POMPERIPHERALID0) [address = FFA04FE0h]**

|          |  |  |  |  |  |  |  |             |   |  |  |  |  |  |  |    |   |
|----------|--|--|--|--|--|--|--|-------------|---|--|--|--|--|--|--|----|---|
| 31       |  |  |  |  |  |  |  |             |   |  |  |  |  |  |  | 16 |   |
| Reserved |  |  |  |  |  |  |  |             |   |  |  |  |  |  |  |    |   |

## ***Enhanced Pulse Width Modulator (ePWM) Module***

---

---

The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipments. The features supported by the ePWM make it especially suitable for digital motor control.

| Topic                                  | Page       |

## 19.1 Introduction

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel modules with separate resources that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In this document the letter x within a signal or module name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and likewise EPWM4A and EPWM4B belong to ePWM4.

### 19.1.1 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in [Figure 19-1](#). Each ePWM instance is identical and is indicated by a numerical value starting with 1. For example ePWM1 is the first instance and ePWM3 is the 3rd instance in the system and ePWMx indicates any instance.

The ePWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral modules (eCAP). Modules can also operate stand-alone.

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- All events can trigger both CPU interrupts and ADC start of conversion (SOC)
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in [Figure 19-1](#). The signals are described in detail in subsequent sections.

Each ePWM module consists of eight submodules and is connected within a system via the signals shown in [Figure 19-2](#).

**Figure 19-1. Multiple ePWM Modules**

**Figure 19-2. Submodules and Signal Connections for an ePWM Module**

The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB).**

The PWM output signals are made available external to the device through the I/O Multiplexing Module (IOMM) as described in the IOMM chapter of the device's technical reference manual.

- **Trip-zone signals ( $\overline{TZ1}$  to  $\overline{TZ6}$ ).**

These input signals alert the ePWM module of fault conditions external to the ePWM module. Each ePWM module can be configured to either use or ignore any of the trip-zone signals. The  $\overline{TZ1}$  to  $\overline{TZ3}$  trip-zone signals can be configured as asynchronous inputs, or double-synchronized using VCLK4, or double-synchronized and filtered through a 6-VCLK4-cycle counter before connecting to the ePWM modules. This selection is done by configuring registers in the IOMM.  $\overline{TZ4}$  is connected to an inverted eQEP1 error signal (EQEP1ERR), or to an inverted eQEP2 error signal (EQEP2ERR), or an OR-combination of EQEP1ERR and EQEP2ERR. This selection is also done via the IOMM registers.  $\overline{TZ5}$  is connected to the system clock fail status. This is asserted whenever an oscillator failure is detected, or a PLL slip is detected.  $\overline{TZ6}$  is connected to the debug mode entry indicator output from the CPU. This allows you to configure a trip action when the CPU halts.

- **Time-base synchronization input (EPWMxSYNCl) and output (EPWMxSYNCO) signals.**

The synchronization signals daisy chain the ePWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins only for ePWM1 (ePWM module #1). The synchronization output for ePWM1 (EPWM1SYNCO) is also connected to the SYNCl of the first enhanced capture module (eCAP1).

- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB).**

Each ePWM module has two ADC start of conversion signals. Any ePWM module can trigger a start of conversion. Which event triggers the start of conversion is configured in the Event-Trigger submodule of the ePWM.

- **Peripheral Bus**

The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

### 19.1.2 Register Mapping

The complete ePWM module control and status register set is grouped by submodule as shown in [Table 19-1](#). Each register set is duplicated for each instance of the ePWM module. The start address for each ePWM register file instance on a device is specified in the specific part's datasheet.

**Table 19-1. ePWM Module Control and Status Register Set Grouped by Submodule**

## 19.2 ePWM Submodules

Eight submodules are included in every ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

### 19.2.1 Overview

[Table 19-2](#) lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in [Section 19.2.3](#) for relevant details.

**Table 19-2. Submodule Configuration Parameters**

| Submodule            | Configuration Parameter or Option                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

Code examples are provided in the remainder of this document that show how to implement various ePWM module configurations. These examples use the constant definitions in the device *EPwm\_defines.h* file in the device-specific header file and peripheral examples software package.

## 19.2.2 Time-Base (TB) Submodule

Each ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system. Figure 19-3 illustrates the time-base module's place within the ePWM.

**Figure 19-3. Time-Base Submodule Block Diagram**

### 19.2.2.1 Purpose of the Time-Base Submodule

You can configure the time-base submodule for the following:

- Specify the ePWM time-base counter (TBCTR) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - CTR = PRD: Time-base counter equal to the specified period (TBCTR = TBPRD) .
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000).
- Configure the rate of the time-base clock; a prescaled version of the device peripheral clock domain (VCLK4). This allows the time-base counter to increment/decrement at a slower rate.

### 19.2.2.2 Controlling and Monitoring the Time-base Submodule

Table 19-3 shows the registers used to control and monitor the time-base submodule.

**Table 19-3. Time-Base Submodule Registers**

| Register | Address offset | Shadowed | Description                |
|----------|----------------|----------|----------------------------|
| TBCTL    | 0x0002         | No       | Time-Base Control Register |
| TBSTS    | 0x0000         | No       | Time-Base Status Register  |
| TBPHS    | 0x0004         | No       | Time-Base Phase Register   |
| TBCTR    | 0x000A         | No       | Time-Base Counter Register |
| TBPRD    | 0x0008         | Yes      | Time-Base Period Register  |

The block diagram in Figure 19-4 shows the critical signals and registers of the time-base submodule. Table 19-4 provides descriptions of the key signals associated with the time-base submodule.

**Figure 19-4. Time-Base Submodule Signals and Registers**

A. These signals are generated by the digital compare (DC) submodule.

**Table 19-4. Key Time-Base Signals**

| Signal     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EPWMxSYNCl | Time-base synchronization input.<br><br>Input pulse used to synchronize the time-base counter with the counter of ePWM module earlier in the synchronization chain. An ePWM peripheral can be configured to use or ignore this signal. For the first ePWM module (EPWM1) this signal comes from a device pin or from the N2HET1 module. For subsequent ePWM modules this signal is passed from another ePWM peripheral. For example, EPWM2SYNCl is generated by the ePWM1 peripheral, EPWM3SYNCl is generated by ePWM2 and so forth. See <a href="#">Section 19.2.2.3.3</a> for information on the synchronization order of a particular device. |
| EPWMxSYNCO | Time-base synchronization output.<br><br>This output pulse is used to synchronize the counter of an ePWM module later in the synchronization chain. The ePWM module generates this signal from one of three event sources:<br><ol style="list-style-type: none"> <li>1. EPWMxSYNCl (Synchronization input pulse)</li> <li>2. CTR = Zero: The time-base counter equal to zero (TBCTR = 0x0000).</li> <li>3. CTR = CMPB: The time-base counter equal to the counter-compare B (TBCTR = CMPB) register.</li> </ol>                                                                                                                                  |
| CTR = PRD  | Time-base counter equal to the specified period.<br><br>This signal is generated whenever the counter value is equal to the active period register value. That is when TBCTR = TBPRD.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| CTR = Zero | Time-base counter equal to zero<br><br>This signal is generated whenever the counter value is zero. That is when TBCTR equals 0x0000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| CTR = CMPB | Time-base counter equal to active counter-compare B register (TBCTR = CMPB).<br><br>This event is generated by the counter-compare submodule and used by the synchronization out logic                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| CTR_dir    | Time-base counter direction.<br><br>Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| CTR_max    | Time-base counter equal max value. (TBCTR = 0xFFFF)<br><br>Generated event when the TBCTR value reaches its maximum value. This signal is only used only as a status bit                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| TBCLK      | Time-base clock.<br><br>This is a prescaled version of the system clock (VCLK4) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.                                                                                                                                                                                                                                                                                                                                                                                                                               |

### 19.2.2.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. [Figure 19-5](#) shows the period ( $T_{pwm}$ ) and frequency ( $F_{pwm}$ ) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (VCLK4).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down-Count Mode:**

In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.

- **Up-Count Mode:**

In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.

- **Down-Count Mode:**

In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

**Figure 19-5. Time-Base Frequency and Period**

### 19.2.2.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register**

The active register controls the hardware and is responsible for actions that the hardware causes or invokes.

- **Shadow Register**

The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDL] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:**

The TBPRD shadow register is enabled when TBCTL[PRDL] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCTR = 0x0000). By default the TBPRD shadow register is enabled.

- **Time-Base Period Immediate Load Mode:**

If immediate load mode is selected (TBCTL[PRDL] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

### 19.2.2.3.2 Time-Base Clock Synchronization

Bit 1 of the device-level multiplexing control module (IOMM) register PINMMR37 is defined as the TBCLKSYNC bit. The TBCLKSYNC bit allows users to globally synchronize all enabled ePWM modules to the time-base clock (TBCLK). When set, all enabled ePWM module clocks are started with the first rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescalers for each ePWM module must be set identically.

The proper procedure for enabling ePWM clocks is as follows:

1. Enable ePWM module clocks using the IOMM control registers for each ePWM module instance
2. Set TBCLKSYNC = 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure ePWM modules: prescaler values and ePWM modes.
4. Set TBCLKSYNC = 1.

### 19.2.2.3.3 Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the ePWM modules on a device. Each ePWM module has a synchronization input (EPWMxSYNCl) and a synchronization output (EPWMxSYNCO). The input synchronization for the first instance (ePWM1) comes from an external pin. The synchronization connections for the remaining ePWM modules are shown in Figure 19-6.

Figure 19-6. Time-Base Counter Synchronization Scheme

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCTR) of the ePWM module will be automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCl: Synchronization Input Pulse:**

The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCTR). This operation occurs on the next valid time-base clock (TBCLK) edge.

The delay from internal master module to slave modules is given by:

- if ( TBCLK = VCLK4): 2 x VCLK4
- if ( TBCLK != VCLK4): 1 TBCLK

- **Software Forced Synchronization Pulse:**

Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCl.

- **Digital Compare Event Synchronization Pulse:**

DCAEVT1 and DCBEVT1 digital compare events can be configured to generate synchronization pulses which have the same affect as EPWMxSYNCl.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PSHDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The PSHDIR bit is ignored in count-up or count-down modes. See [Figure 19-7](#) through [Figure 19-10](#) for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, you can set up a master time-base (for example, ePWM1) and downstream modules (ePWM2 - ePWMx) may elect to run in synchronization with the master.

#### 19.2.2.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKSYNC bit can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. When TBCLKSYNC = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKSYNC = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is as follows:

1. Enable ePWM module clocks using the IOMM control registers for each ePWM module instance
2. Set TBCLKSYNC = 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure ePWM modules: prescaler values and ePWM modes.
4. Set TBCLKSYNC = 1.

### 19.2.2.5 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical
- Frozen where the time-base counter is held constant at the current value

To illustrate the operation of the first three modes, the following timing diagrams show when events are generated and how the time-base responds to an EPWMxSYNCl signal.

**Figure 19-7. Time-Base Up-Count Mode Waveforms**

**Figure 19-8. Time-Base Down-Count Mode Waveforms**

**Figure 19-9. Time-Base Up-Down-Count Waveforms, TBCTL[PHSDIR = 0] Count Down On Synchronization Event**

**Figure 19-10. Time-Base Up-Down Count Waveforms, TBCTL[PHSDIR = 1] Count Up On Synchronization Event**

### 19.2.3 Counter-Compare (CC) Submodule

Figure 19-11 illustrates the counter-compare submodule within the ePWM.

Figure 19-11. Counter-Compare Submodule

Figure 19-12 shows the basic structure of the counter-compare submodule.

#### 19.2.3.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA) and counter-compare B (CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare:

- Generates events based on programmable time stamps using the CMPA and CMPB registers
  - $CTR = CMPA$ : Time-base counter equals counter-compare A register ( $TBCTR = CMPA$ ).
  - $CTR = CMPB$ : Time-base counter equals counter-compare B register ( $TBCTR = CMPB$ ).
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

### 19.2.3.2 Controlling and Monitoring the Counter-Compare Submodule

The counter-compare submodule operation is controlled and monitored by the registers shown in [Table 19-5](#):

**Table 19-5. Counter-Compare Submodule Registers**

| Register Name | Address Offset | Shadowed | Description                       |
|---------------|----------------|----------|-----------------------------------|
| CMPCTL        | 0x000C         | No       | Counter-Compare Control Register. |
| CMPA          | 0x0010         | Yes      | Counter-Compare A Register        |
| CMPB          | 0x0016         | Yes      | Counter-Compare B Register        |

**Figure 19-12. Detailed View of the Counter-Compare Submodule**

The key signals associated with the counter-compare submodule are described in [Table 19-6](#).

**Table 19-6. Counter-Compare Submodule Key Signals**

| Signal     | Description of Event                                                                                                            | Registers Compared |
|------------|---------------------------------------------------------------------------------------------------------------------------------|--------------------|
| CTR = CMPA | Time-base counter equal to the active counter-compare A value                                                                   | TBCTR = CMPA       |
| CTR = CMPB | Time-base counter equal to the active counter-compare B value                                                                   | TBCTR = CMPB       |
| CTR = PRD  | Time-base counter equal to the active period.<br>Used to load active counter-compare A and B registers from the shadow register | TBCTR = TBPRD      |
| CTR = ZERO | Time-base counter equal to zero.<br>Used to load active counter-compare A and B registers from the shadow register              | TBCTR = 0x0000     |

### 19.2.3.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCTR = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCTR = CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle if the compare value is between 0x0000-TBPRD and once per cycle if the compare value is equal to 0x0000 or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to [Section 19.2.4.1](#) for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occur at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPA shadow register and CMPB shadow register respectively. The behavior of the two load modes is described below:

#### Shadow Mode:

The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL[LOADAMODE] and CMPCTL[LOADBMODE] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000)
- Both CTR = PRD and CTR = Zero

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

#### Immediate Load Mode:

If immediate load mode is selected (that is, TBCTL[SHADWAMODE] = 1 or TBCTL[SHADWBMODE] = 1), then a read from or a write to the register will go directly to the active register.

### 19.2.3.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in [Figure 19-13](#) through [Figure 19-16](#) show when events are generated and how the EPWMxSYNCl signal interacts.

**Figure 19-13. Counter-Compare Event Waveforms in Up-Count Mode**

NOTE: An EPWMxSYNCl external synchronization event can cause a discontinuity in the TBCTR count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

**Figure 19-14. Counter-Compare Events in Down-Count Mode**

The diagram shows the timing of several signals over time. The top signal is TBPRD (value), which is a sawtooth wave. The y-axis is labeled TBCTR[15:0] and has markers for 0xFFFF, TBPRD (value), CMPA (value), CMPB (value), TBPHS (value), and 0x0000. The TBPRD signal starts at 0x0000, ramps up to TBPRD (value), then ramps down. It has a period of two TBPRD (value) intervals. The CMPA (value) and CMPB (value) signals are also shown as horizontal lines. The TBPHS (value) signal is a sawtooth wave that starts at 0x0000, ramps up to TBPHS (value), then ramps down. The EPWMxSYNCl signal is a square wave that is high during the TBPHS (value) interval. The CTR = CMPB signal is a square wave that is high during the CMPB (value) interval. The CTR = CMPA signal is a square wave that is high during the CMPA (value) interval.

The diagram illustrates the timing of the TBCTR[15:0] register. The vertical axis represents the value of TBCTR[15:0], ranging from 0x0000 to 0xFFFF. The horizontal axis represents time. The TBCTR[15:0] signal is shown as a sawtooth waveform that increments from 0x0000 to TBPRD (value) and then decrements back to 0x0000. The CMPA (value) and CMPB (value) are shown as horizontal lines. The TBPBS (value) is shown as a horizontal line. The EPWMxSYNCl signal is shown as a periodic square wave. The CTR = CMPB signal is shown as a periodic square wave. The CTR = CMPA signal is shown as a periodic square wave.

## 19.2.4 Action-Qualifier (AQ) Submodule

Figure 19-17 shows the action-qualifier (AQ) submodule (see shaded block) in the ePWM system.

The action-qualifier submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

**Figure 19-17. Action-Qualifier Submodule**

### 19.2.4.1 Purpose of the Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000)
  - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCTR = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing.

### 19.2.4.2 Action-Qualifier Submodule Control and Status Register Definitions

The action-qualifier submodule operation is controlled and monitored via the registers in Table 19-7.

**Table 19-7. Action-Qualifier Submodule Registers**

| Register Name | Address offset | Shadowed | Description                                             |
|---------------|----------------|----------|---------------------------------------------------------|
| AQCTLA        | 0x0014         | No       | Action-Qualifier Control Register For Output A (EPWMxA) |
| AQCTLB        | 0x001A         | No       | Action-Qualifier Control Register For Output B (EPWMxB) |
| AQSFRC        | 0x0018         | No       | Action-Qualifier Software Force Register                |
| AQCSFRC       | 0x001E         | Yes      | Action-Qualifier Continuous Software Force              |

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers shown in [Table 19-7](#).

**Figure 19-18. Action-Qualifier Submodule Inputs and Outputs**

For convenience, the possible input events are summarized again in [Table 19-8](#).

**Table 19-8. Action-Qualifier Submodule Possible Input Events**

| Signal                | Description                                      | Registers Compared |
|-----------------------|--------------------------------------------------|--------------------|
| CTR = PRD             | Time-base counter equal to the period value      | TBCTR = TBPRD      |
| CTR = Zero            | Time-base counter equal to zero                  | TBCTR = 0x0000     |
| CTR = CMPA            | Time-base counter equal to the counter-compare A | TBCTR = CMPA       |
| CTR = CMPB            | Time-base counter equal to the counter-compare B | TBCTR = CMPB       |
| Software forced event | Asynchronous event initiated by software         |                    |

The software forced action is a useful asynchronous event. This control is handled by registers AQSFR and AQCSFRC.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:**  
Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:**  
Set output EPWMxA or EPWMxB to a low level.
- **Toggle:**  
If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:**  
Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts and ADC start of conversion. See the Event-trigger Submodule description in [Section 19.2.8](#) for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this document use a set of symbolic actions. These symbols are summarized in [Figure 19-19](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

**Figure 19-19. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs**

| S/W<br>force                                                                        | TB Counter equals:                                                                  |                                                                                     |                                                                                     |                                                                                       | Actions    |
|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|------------|
|                                                                                     | Zero                                                                                | Comp<br>A                                                                           | Comp<br>B                                                                           | Period                                                                                |            |
|  |  |  |  |  | Do Nothing |
|  |  |  |  |  | Clear Low  |
|  |  |  |  |  | Set High   |
|  |  |  |  |  | Toggle     |

### 19.2.4.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in [Table 19-9](#). A priority level of 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCTR.

**Table 19-9. Action-Qualifier Event Priority for Up-Down-Count Mode**

| Priority Level | Event If TBCTR is Incrementing<br>TBCTR = Zero up to TBCTR = TBPRD | Event If TBCTR is Decrementing<br>TBCTR = TBPRD down to TBCTR = 1 |
|----------------|--------------------------------------------------------------------|-------------------------------------------------------------------|
| 1 (Highest)    | Software forced event                                              | Software forced event                                             |
| 2              | Counter equals CMPB on up-count (CBU)                              | Counter equals CMPB on down-count (CBD)                           |
| 3              | Counter equals CMPA on up-count (CAU)                              | Counter equals CMPA on down-count (CAD)                           |
| 4              | Counter equals zero                                                | Counter equals period (TBPRD)                                     |
| 5              | Counter equals CMPB on down-count (CBD)                            | Counter equals CMPB on up-count (CBU)                             |
| 6 (Lowest)     | Counter equals CMPA on down-count (CAD)                            | Counter equals CMPA on up-count (CBU)                             |

[Table 19-10](#) shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

**Table 19-10. Action-Qualifier Event Priority for Up-Count Mode**

| Priority Level | Event                                   |
|----------------|-----------------------------------------|
| 1 (Highest)    | Software forced event                   |
| 2              | Counter equal to period (TBPRD)         |
| 3              | Counter equal to CMPB on up-count (CBU) |
| 4              | Counter equal to CMPA on up-count (CAU) |
| 5 (Lowest)     | Counter equal to Zero                   |

[Table 19-11](#) shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

**Table 19-11. Action-Qualifier Event Priority for Down-Count Mode**

| Priority Level | Event                                     |
|----------------|-------------------------------------------|
| 1 (Highest)    | Software forced event                     |
| 2              | Counter equal to Zero                     |
| 3              | Counter equal to CMPB on down-count (CBD) |
| 4              | Counter equal to CMPA on down-count (CAD) |
| 5 (Lowest)     | Counter equal to period (TBPRD)           |

It is possible to set the compare value greater than the period. In this case the action will take place as shown in [Table 19-12](#).

**Table 19-12. Behavior if CMPA/CMPB is Greater than the Period**

| Counter Mode       | Compare on Up-Count Event<br>CAD/CBD                                                                                                                                                                                                        | Compare on Down-Count Event<br>CAD/CBD                                                                                                                                                                                                |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Up-Count Mode      | <p>If <math>CMPA/CMPB \leq TBPRD</math> period, then the event occurs on a compare match (TBCTR=CMPA or CMPB).</p> <p>If <math>CMPA/CMPB &gt; TBPRD</math>, then the event will not occur.</p>                                              | Never occurs.                                                                                                                                                                                                                         |

#### 19.2.4.4 Waveforms for Common Configurations

**NOTE:** The waveforms in this document show the ePWMs behavior for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place; either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

**Use up-down-count mode to generate a symmetric PWM:**

- If you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1.

This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

**Use up-down-count mode to generate an asymmetric PWM:**

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

**When using up-count mode to generate an asymmetric PWM:**

- To achieve 0-100% asymmetric PWM use the following configuration: Load CMPA/CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

See the *Using Enhanced Pulse Width Modulator (ePWM) Module for 0-100% Duty Cycle Control* Application Report (literature number [SPRAA11](#))

Figure 19-20 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCTR. In this mode 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When CMPA = 0, the PWM signal is low for the entire period giving the 0% duty waveform. When CMPA = TBPRD, the PWM signal is high achieving 100% duty.

When using this configuration in practice, if you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

**Figure 19-20. Up-Down-Count Mode Symmetrical Waveform**

The PWM waveforms in [Figure 19-21](#) through [Figure 19-26](#) show some common action-qualifier configurations. The C-code samples in [Example 19-1](#) through [Example 19-6](#) shows how to configure an ePWM module for each case. Some conventions used in the figures and examples are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

**Figure 19-21. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB—Active High**

- PWM period =  $(TBPRD + 1) \times T_{TBCLK}$
- Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
- Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).
- The "Do Nothing" actions ( X ) are shown for completeness, but will not be shown on subsequent diagrams.
- Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

[Example 19-1](#) contains a code sample showing initialization and run time for the waveforms in [Figure 19-21](#).

**Example 19-1. Code Sample for [Figure 19-21](#)**

```
// Initialization Time
// =====
EPwm1Regs.TBPRD = 600;                // Period = 601 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 350;       // Compare A = 350 TBCLK counts
EPwm1Regs.CMPB = 200;                 // Compare B = 200 TBCLK counts
EPwm1Regs.TBPHS = 0;                  // Set Phase register to zero
EPwm1Regs.TBCTR = 0;                  // clear TB counter
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Phase loading disabled
EPwm1Regs.TBCTL.bit.PRDL = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1; // TBCLK = SYSCLK
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_SET;
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;
//
// Run Time
// =====
EPwm1Regs.CMPA.half.CMPA = Duty1A;    // adjust duty for output EPWM1A
EPwm1Regs.CMPB = Duty1B;              // adjust duty for output EPWM1B
```

**Figure 19-22. Up, Single Edge Asymmetric Waveform With Independent Modulation on EPWMxA and EPWMxB—Active Low**

- A  $PWM\ period = (TBPRD + 1) \times T_{TBCLK}$
- B Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
- C Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
- D Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

[Example 19-2](#) contains a code sample showing initialization and run time for the waveforms in [Figure 19-22](#).

**Example 19-2. Code Sample for Figure 19-22**

```
// Initialization Time
// =====
EPwm1Regs.TBPRD = 600;                // Period = 601 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 350;       // Compare A = 350 TBCLK counts
EPwm1Regs.CMPB = 200;                 // Compare B = 200 TBCLK counts
EPwm1Regs.TBPHS = 0;                  // Set Phase register to zero
EPwm1Regs.TBCTR = 0;                  // clear TB counter
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Phase loading disabled
EPwm1Regs.TBCTL.bit.PRDL = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1; // TBCLK = VCLK4
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on TBCTR = Zero
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on TBCTR = Zero
EPwm1Regs.AQCTLA.bit.PR = AQ_CLEAR;
EPwm1Regs.AQCTLA.bit.CAU = AQ_SET;
EPwm1Regs.AQCTLB.bit.PR = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.CBU = AQ_SET;
//
// Run Time
// =====
EPwm1Regs.CMPA.half.CMPA = Duty1A;    // adjust duty for output EPWM1A
EPwm1Regs.CMPB = Duty1B;              // adjust duty for output EPWM1B
```

**Figure 19-23. Up-Count, Pulse Placement Asymmetric Waveform With Independent Modulation on EPWMxA**

- A  $PWM\ frequency = 1 / ((TBPRD + 1) \times T_{TBCLK})$
- B Pulse can be placed anywhere within the PWM cycle (0000 - TBPRD)
- C High time duty proportional to (CMPB - CMPA)
- D EPWMxB can be used to generate a 50% duty square wave with frequency =  $1/2 \times ((TBPRD + 1) \times TBCLK)$

Example 19-3 contains a code sample showing initialization and run time for the waveforms in Figure 19-23.

### Example 19-3. Code Sample for Figure 19-23

```
// Initialization Time
// = = = = =
EPwm1Regs.TBPRD = 600;                // Period = 601 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 200;       // Compare A = 200 TBCLK counts
EPwm1Regs.CMPB = 400;                 // Compare B = 400 TBCLK counts
EPwm1Regs.TBPHS = 0;                  // Set Phase register to zero
EPwm1Regs.TBCTR = 0;                  // clear TB counter
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Phase loading disabled
EPwm1Regs.TBCTL.bit.PRDL = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1; // TBCLK = VCLK4
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on TBCTR = Zero
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on TBCTR = Zero
EPwm1Regs.AQCTLA.bit.CAU = AQ_SET;
EPwm1Regs.AQCTLA.bit.CBU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_TOGGLE;
//
// Run Time
// = = = = =
EPwm1Regs.CMPA.half.CMPA = EdgePosA; // adjust duty for output EPWM1A only
EPwm1Regs.CMPB = EdgePosB;
```

**Figure 19-24. Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Active Low**

- A PWM period =  $2 \times \text{TBPRD} \times T_{\text{TBCLK}}$
- B Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
- C Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
- D Outputs EPWMxA and EPWMxB can drive independent power switches

Example 19-4 contains a code sample showing initialization and run time for the waveforms in Figure 19-24.

#### Example 19-4. Code Sample for Figure 19-24

```
// Initialization Time
// =====
EPwm1Regs.TBPRD = 600; // Period = 2*600 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 400; // Compare A = 400 TBCLK counts
EPwm1Regs.CMPB = 500; // Compare B = 500 TBCLK counts
EPwm1Regs.TBPHS = 0; // Set Phase register to zero
EPwm1Regs.TBCTR = 0; // clear TB counter
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UPDOWN; // Symmetric
xEPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Phase loading disabled
xEPwm1Regs.TBCTL.bit.PRDL = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1; // TBCLK = VCLK4
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.AQCTLA.bit.CAU = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAD = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.CBU = AQ_SET;
EPwm1Regs.AQCTLB.bit.CBD = AQ_CLEAR;
//
// Run Time
// =====
EPwm1Regs.CMPA.half.CMPA = Duty1A; // adjust duty for output EPWM1A
EPwm1Regs.CMPB = Duty1B; // adjust duty for output EPWM1B
```

**Figure 19-25. Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Complementary**

- A PWM period =  $2 \times \text{TBPRD} \times T_{\text{TBCLK}}$
- B Duty modulation for EPWMxA is set by CMPA, and is active low, that is, low time duty proportional to CMPA
- C Duty modulation for EPWMxB is set by CMPB and is active high, that is, high time duty proportional to CMPB
- D Outputs EPWMx can drive upper/lower (complementary) power switches
- E Dead-band = CMPB - CMPA (fully programmable edge placement by software). Note the dead-band module is also available if the more classical edge delay method is required.

Example 19-5 contains a code sample showing initialization and run time for the waveforms in Figure 19-25.

#### Example 19-5. Code Sample for Figure 19-25

```
// Initialization Time
// =====
EPwm1Regs.TBPRD = 600; // Period = 2'600 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 350; // Compare A = 350 TBCLK counts
EPwm1Regs.CMPB = 400; // Compare B = 400 TBCLK counts
EPwm1Regs.TBPHS = 0; // Set Phase register to zero
EPwm1Regs.TBCTR = 0; // clear TB counter
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UPDOWN; // Symmetric
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Phase loading disabled
EPwm1Regs.TBCTL.bit.PRDL = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1; // TBCLK = VCLK4
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.AQCTLA.bit.CAU = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAD = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.CBD = AQ_SET;
// Run Time
// =====
EPwm1Regs.CMPA.half.CMPA = Duty1A; // adjust duty for output EPWM1A
EPwm1Regs.CMPB = Duty1B; // adjust duty for output EPWM1B
```

**Figure 19-26. Up-Down-Count, Dual Edge Asymmetric Waveform, With Independent Modulation on EPWMxA—Active Low**

- A PWM period =  $2 \times \text{TBPRD} \times \text{TBCLK}$
- B Rising edge and falling edge can be asymmetrically positioned within a PWM cycle. This allows for pulse placement techniques.
- C Duty modulation for EPWMxA is set by CMPA and CMPB.
- D Low time duty for EPWMxA is proportional to (CMPA + CMPB).
- E To change this example to active high, CMPA and CMPB actions need to be inverted (that is, Set ! Clear and Clear Set).
- F Duty modulation for EPWMxB is fixed at 50% (utilizes spare action resources for EPWMxB)

Example 19-6 contains a code sample showing initialization and run time for the waveforms in Figure 19-26.

#### Example 19-6. Code Sample for Figure 19-26

```
// Initialization Time
// =====
EPwm1Regs.TBPRD = 600;                // Period = 2 * 600 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 250;      // Compare A = 250 TBCLK counts
EPwm1Regs.CMPB = 450;                // Compare B = 450 TBCLK counts
EPwm1Regs.TBPHS = 0;                 // Set Phase register to zero
EPwm1Regs.TBCTR = 0;                 // clear TB counter
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UPDOWN; // Symmetric
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Phase loading disabled
EPwm1Regs.TBCTL.bit.PRDL = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1; // TBCLK = VCLK4
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;

EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on CTR = Zero
EPwm1Regs.AQCTLA.bit.CAU = AQ_SET;
EPwm1Regs.AQCTLA.bit.CBD = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.PRDL = AQ_SET;
// Run Time
// =====
EPwm1Regs.CMPA.half.CMPA = EdgePosA; // adjust duty for output EPWM1A only
EPwm1Regs.CMPB = EdgePosB;
```

## 19.2.5 Dead-Band Generator (DB) Submodule

Figure 19-27 illustrates the dead-band submodule within the ePWM module.

Figure 19-27. Dead\_Band Submodule

### 19.2.5.1 Purpose of the Dead-Band Submodule

Section 19.2.4 discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band submodule described here should be used.

The key functions of the dead-band module are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

### 19.2.5.2 Controlling and Monitoring the Dead-Band Submodule

The dead-band submodule operation is controlled and monitored via the following registers:

Table 19-13. Dead-Band Generator Submodule Registers

| Register Name | Address offset | Shadowed | Description                                 |
|---------------|----------------|----------|---------------------------------------------|
| DBCTL         | 0x001C         | No       | Dead-Band Control Register                  |
| DBRED         | 0x0022         | No       | Dead-Band Rising Edge Delay Count Register  |
| DBFED         | 0x0020         | No       | Dead-Band Falling Edge Delay Count Register |

### 19.2.5.3 Operational Highlights for the Dead-Band Submodule

The following sections provide the operational highlights.

The dead-band submodule has two groups of independent selection options as shown in [Figure 19-28](#).

- **Input Source Selection:**

The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the DBCTL[IN\_MODE] control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:

- EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
- EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
- EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
- EPWMxB In is the source for both falling-edge and rising-edge delay.

- **Half Cycle Clocking:**

The dead-band submodule can be clocked using half cycle clocking to double the resolution (that is, counter clocked at  $2 \times \text{TBCLK}$ )

- **Output Mode Control:**

The output mode is configured by way of the DBCTL[OUT\_MODE] bits. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.

- **Polarity Control:**

The polarity control (DBCTL[POLSEL]) allows you to specify whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

**Figure 19-28. Configuration Options for the Dead-Band Submodule**

Although all combinations are supported, not all are typical usage modes. [Table 19-14](#) documents some classical dead-band configurations. These modes assume that the DBCTL[IN\_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in [Table 19-14](#) fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)**  
Allows you to fully disable the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings:**  
These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in [Figure 19-29](#). Note that to generate equivalent waveforms to [Figure 19-29](#), configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay**  
Finally the last two entries in [Table 19-14](#) show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

**Table 19-14. Classical Dead-Band Operating Modes**

| Mode | Mode Description                               | DBCTL[POLSEL] |        | DBCTL[OUT_MODE] |    |
|------|------------------------------------------------|---------------|--------|-----------------|----|
|      |                                                | S3            | S2     | S1              | S0 |
| 1    | EPWMxA and EPWMxB Passed Through (No Delay)    | X             | X      | 0               | 0  |
| 2    | Active High Complementary (AHC)                | 1             | 0      | 1               | 1  |
| 3    | Active Low Complementary (ALC)                 | 0             | 1      | 1               | 1  |
| 4    | Active High (AH)                               | 0             | 0      | 1               | 1  |
| 5    | Active Low (AL)                                | 1             | 1      | 1               | 1  |
| 6    | EPWMxA Out = EPWMxA In (No Delay)              | 0 or 1        | 0 or 1 | 0               | 1  |
|      | EPWMxB Out = EPWMxA In with Falling Edge Delay |               |        |                 |    |
| 7    | EPWMxA Out = EPWMxA In with Rising Edge Delay  | 0 or 1        | 0 or 1 | 1               | 0  |
|      | EPWMxB Out = EPWMxB In with No Delay           |               |        |                 |    |

Figure 19-29 shows waveforms for typical cases where  $0\% < \text{duty} < 100\%$ .

**Figure 19-29. Dead-Band Waveforms for Typical Cases ( $0\% < \text{Duty} < 100\%$ )**

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formula to calculate falling-edge-delay and rising-edge-delay are:

$$\text{FED} = \text{DBFED} \times T_{\text{TBCLK}}$$

$$\text{RED} = \text{DBRED} \times T_{\text{TBCLK}}$$

Where  $T_{\text{TBCLK}}$  is the period of TBCLK, the prescaled version of VCLK4.

For convenience, delay values for various TBCLK options are shown in [Table 19-15](#).

**Table 19-15. Dead-Band Delay Values in  $\mu\text{S}$  as a Function of DBFED and DBRED**

| Dead-Band Value | Dead-Band Delay in $\mu\text{S}$ |                     |                     |
|-----------------|----------------------------------|---------------------|---------------------|
|                 | DBFED, DBRED                     | TBCLK = VCLK4 / 2   | TBCLK = VCLK4 / 4   |
| 1               | 0.02 $\mu\text{S}$               | 0.03 $\mu\text{S}$  | 0.07 $\mu\text{S}$  |
| 5               | 0.08 $\mu\text{S}$               | 0.17 $\mu\text{S}$  | 0.33 $\mu\text{S}$  |
| 10              | 0.17 $\mu\text{S}$               | 0.33 $\mu\text{S}$  | 0.67 $\mu\text{S}$  |
| 100             | 1.67 $\mu\text{S}$               | 3.33 $\mu\text{S}$  | 6.67 $\mu\text{S}$  |
| 200             | 3.33 $\mu\text{S}$               | 6.67 $\mu\text{S}$  | 13.33 $\mu\text{S}$ |
| 400             | 6.67 $\mu\text{S}$               | 13.33 $\mu\text{S}$ | 26.67 $\mu\text{S}$ |
| 500             | 8.33 $\mu\text{S}$               | 16.67 $\mu\text{S}$ | 33.33 $\mu\text{S}$ |
| 600             | 10.00 $\mu\text{S}$              | 20.00 $\mu\text{S}$ | 40.00 $\mu\text{S}$ |
| 700             | 11.67 $\mu\text{S}$              | 23.33 $\mu\text{S}$ | 46.67 $\mu\text{S}$ |
| 800             | 13.33 $\mu\text{S}$              | 26.67 $\mu\text{S}$ | 53.33 $\mu\text{S}$ |
| 900             | 15.00 $\mu\text{S}$              | 30.00 $\mu\text{S}$ | 60.00 $\mu\text{S}$ |
| 1000            | 16.67 $\mu\text{S}$              | 33.33 $\mu\text{S}$ | 66.67 $\mu\text{S}$ |

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

$$\text{FED} = \text{DBFED} \times T_{\text{TBCLK}}/2$$

$$\text{RED} = \text{DBRED} \times T_{\text{TBCLK}}/2$$

## 19.2.6 PWM-Chopper (PC) Submodule

Figure 19-30 illustrates the PWM-chopper (PC) submodule within the ePWM module.

The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if you need pulse transformer-based gate drivers to control the power switching elements.

**Figure 19-30. PWM-Chopper Submodule**

### 19.2.6.1 Purpose of the PWM-Chopper Submodule

The key functions of the PWM-chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

### 19.2.6.2 Controlling the PWM-Chopper Submodule

The PWM-chopper submodule operation is controlled via the registers in Table 19-16.

**Table 19-16. PWM-Chopper Submodule Registers**

| mnemonic | Address offset | Shadowed | Description                  |
|----------|----------------|----------|------------------------------|
| PCCTL    | 0x003E         | No       | PWM-chopper Control Register |

### 19.2.6.3 Operational Highlights for the PWM-Chopper Submodule

Figure 19-31 shows the operational details of the PWM-chopper submodule. The carrier clock is derived from VCLK4. Its frequency and duty cycle are controlled via the  $CHPFREQ$  and  $CHPDUTY$  bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the  $OSHTWTH$  bits. The PWM-chopper submodule can be fully disabled (bypassed) via the  $CHPEN$  bit.

**Figure 19-31. PWM-Chopper Submodule Operational Details**

#### 19.2.6.4 Waveforms

Figure 19-32 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

**Figure 19-32. Simple PWM-Chopper Submodule Waveforms Showing Chopping Action Only**

### 19.2.6.4.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{VCLK4} \times 8 \times OSHTWTH$$

Where  $T_{VCLK4}$  is the period of the system clock (VCLK4) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 19-33 shows the first and subsequent sustaining pulses and Table 7.3 gives the possible pulse width values for a VCLK4 = 100 MHz.

**Figure 19-33. PWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses**

**Table 19-17. Possible Pulse Width Values for VCLK4 = 100 MHz**

| OSHTWTHz<br>(hex) | Pulse Width<br>(nS) |
|-------------------|---------------------|
| 0                 | 100                 |
| 1                 | 200                 |
| 2                 | 300                 |
| 3                 | 400                 |
| 4                 | 500                 |
| 5                 | 600                 |
| 6                 | 700                 |
| 7                 | 800                 |
| 8                 | 900                 |
| 9                 | 1000                |
| A                 | 1100                |
| B                 | 1200                |
| C                 | 1300                |
| D                 | 1400                |
| E                 | 1500                |
| F                 | 1600                |

#### 19.2.6.4.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 19-34 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

**Figure 19-34. PWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses**

### 19.2.7 Trip-Zone (TZ) Submodule

Figure 19-35 shows how the trip-zone (TZ) submodule fits within the ePWM module.

Each ePWM module is connected to six  $\overline{TZn}$  signals ( $\overline{TZ1}$  to  $\overline{TZ6}$ ).  $\overline{TZ1}$  to  $\overline{TZ3}$  are sourced from the GPIO mux.  $\overline{TZ4}$  is sourced from a combination of EQEP1ERR and EQEP2ERR signals.  $\overline{TZ5}$  is connected to the system oscillator or PLL clock fail logic, and  $\overline{TZ6}$  is sourced from the debug mode halt indication output from the CPU. These signals indicate fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur.

**Figure 19-35. Trip-Zone Submodule**

#### 19.2.7.1 Purpose of the Trip-Zone Submodule

The key functions of the Trip-Zone submodule are:

- Trip inputs  $\overline{TZ1}$  to  $\overline{TZ6}$  are mapped to all ePWM modules.
- Upon a fault indication, either no action is taken or the ePWM outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Support for digital compare tripping (DC) based on state of on-chip analog comparator module outputs and/or  $\overline{TZ1}$  to  $\overline{TZ3}$  signals.
- Each trip-zone input and digital compare (DC) submodule DCAEVT1/2 or DCBEVT1/2 force event can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone input.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

### 19.2.7.2 Controlling and Monitoring the Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

**Table 19-18. Trip-Zone Submodule Registers**

| Register Name | Address offset | Shadowed | Description <sup>(1)</sup>                               |
|---------------|----------------|----------|----------------------------------------------------------|
| TZSEL         | 0x0026         | No       | Trip-Zone Select Register                                |
| TZDCSEL       | 0x0024         | No       | Trip-zone Digital Compare Select Register <sup>(2)</sup> |
| TZCTL         | 0x002A         | No       | Trip-Zone Control Register                               |
| TZEINT        | 0x0028         | No       | Trip-Zone Enable Interrupt Register                      |
| TZFLG         | 0x002E         | No       | Trip-Zone Flag Register                                  |
| TZCLR         | 0x002C         | No       | Trip-Zone Clear Register                                 |
| TZFRC         | 0x0032         | No       | Trip-Zone Force Register                                 |

<sup>(1)</sup> All trip-zone registers are writable only in privileged mode.

<sup>(2)</sup> This register is discussed in more detail in [Section 19.2.9](#).

### 19.2.7.3 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals  $\overline{TZ1}$  to  $\overline{TZ6}$  (also collectively referred to as  $\overline{TZn}$ ) are active low input signals. When one of these signals goes low, or when a DCAEVT1/2 or DCBEVT1/2 force happens based on the TZDCSEL register event selection, it indicates that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone signals or DC events. Which trip-zone signals or DC events are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signals may or may not be synchronized to the system clock (VCLK4) and digitally filtered within the GPIO MUX block. A minimum of 3\*TBCLK low pulse width on  $\overline{TZn}$  inputs is sufficient to trigger a fault condition on the ePWM module. If the pulse width is less than this, the trip condition may not be latched. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on  $\overline{TZn}$  inputs. The GPIOs or peripherals must be appropriately configured. For more information, see the IOMM chapter of the device technical reference manual.

Each  $\overline{TZn}$  input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for an ePWM module. DCAEVT1 and DCBEVT1 events can be configured to directly trip an ePWM module or provide a one-shot trip event to the module. Likewise, DCAEVT2 and DCBEVT2 events can also be configured to directly trip an ePWM module or provide a cycle-by-cycle trip event to the module. This configuration is determined by the TZSEL[DCAEVT1/2], TZSEL[DCBEVT1/2], TZSEL[CBCn], and TZSEL[OSHTn] control bits (where n corresponds to the trip input) respectively.

- **Cycle-by-Cycle (CBC):**

When a cycle-by-cycle trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 19-19](#) lists the possible actions. In addition, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMx\_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral.

If the CBC interrupt is enabled via the TZEINT register, and DCAEVT2 or DCBEVT2 are selected as CBC trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT2 or DCBEVT2 interrupts in the TZEINT register, as the DC events trigger interrupts through the CBC mechanism.

The specified condition on the inputs is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x0000) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] flag bit will remain set until it is manually cleared by writing to the TZCLR[CBC] bit. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] bit is cleared, then it will again be immediately set.

- **One-Shot (OSHT):**

When a one-shot trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 19-19](#) lists the possible actions. In addition, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMx\_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit.

If the one-shot interrupt is enabled via the TZEINT register, and DCAEVT1 or DCBEVT1 are selected as OSHT trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT1 or DCBEVT1 interrupts in the TZEINT register, as the DC events trigger interrupts through the OSHT mechanism.

- **Digital Compare Events (DCAEVT1/2 and DCBEVT1/2):**

A digital compare DCAEVT1/2 or DCBEVT1/2 event is generated based on a combination of the DCAH/DCAL and DCBH/DCBL signals as selected by the TZDCSEL register. The signals which source the DCAH/DCAL and DCBH/DCBL signals are selected via the DCTRIPSEL register and can be either trip zone input pins. For more information on the digital compare submodule signals, see [Section 19.2.9](#).

When a digital compare event occurs, the action specified in the TZCTL[DCAEVT1/2] and TZCTL[DCBEVT1/2] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 19-19](#) lists the possible actions. In addition, the relevant DC trip event flag (TZFLG[DCAEVT1/2] / TZFLG[DCBEVT1/2]) is set and a EPWMx\_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral.

The specified condition on the pins is automatically cleared when the DC trip event is no longer present. The TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag bit will remain set until it is manually cleared by writing to the TZCLR[DCAEVT1/2] or TZCLR[DCBEVT1/2] bit. If the DC trip event is still present when the TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag is cleared, then it will again be immediately set.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL register bit fields. One of four possible actions, shown in [Table 19-19](#), can be taken on a trip event.

**Table 19-19. Possible Actions On a Trip Event**

| TZCTL Register bit-field Settings | EPWMxA and/or EPWMxB | Comment                                         |
|-----------------------------------|----------------------|-------------------------------------------------|
| 0,0                               | High-Impedance       | Tripped                                         |
| 0,1                               | Force to High State  | Tripped                                         |
| 1,0                               | Force to Low State   | Tripped                                         |
| 1,1                               | No Change            | Do Nothing.<br>No change is made to the output. |

### Example 19-7. Trip-Zone Configurations

#### Scenario A:

A one-shot trip event on  $\overline{TZ1}$  pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM2
  - TZCTL[TZA] = 1: EPWM2A will be forced high on a trip event.
  - TZCTL[TZB] = 1: EPWM2B will be forced high on a trip event.

#### Scenario B:

A cycle-by-cycle event on  $\overline{TZ5}$  pulls both EPWM1A, EPWM1B low.

A one-shot event on  $\overline{TZ1}$  or  $\overline{TZ6}$  puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
  - TZSEL[CBC5] = 1: enables  $\overline{TZ5}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM2
  - TZSEL[OSHT6] = 1: enables  $\overline{TZ6}$  as a one-shot event source for ePWM2
  - TZCTL[TZA] = 0: EPWM2A will be put into a high-impedance state on a trip event.
  - TZCTL[TZB] = 3: EPWM2B will ignore the trip event.

#### 19.2.7.4 Generating Trip Event Interrupts

Figure 19-36 and Figure 19-37 illustrate the trip-zone submodule control and interrupt logic, respectively. DCAEVT1/2 and DCBEVT1/2 signals are described in further detail in Section 19.2.9.

**Figure 19-36. Trip-Zone Submodule Mode Control Logic**

Figure 19-37. Trip-Zone Submodule Interrupt Logic

### 19.2.8 Event-Trigger (ET) Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base, counter-compare and digital-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests and ADC start of conversion at:
  - Every event
  - Every second event
  - Every third event
- Provides full visibility of event generation via event counters and flags
- Allows software forcing of Interrupts and ADC start of conversion

The event-trigger submodule manages the events generated by the time-base submodule, the counter-compare submodule, and the digital-compare submodule to generate an interrupt to the CPU and/or a start of conversion pulse to the ADC when a selected event occurs. Figure 19-38 illustrates where the event-trigger submodule fits within the ePWM system.

**Figure 19-38. Event-Trigger Submodule**

#### 19.2.8.1 Operational Overview of the Event-Trigger Submodule

The following sections describe the event-trigger submodule's operational highlights.

Each ePWM module has one interrupt request line connected to the VIM and two start of conversion signals connected to the ADC module. As shown in Figure 19-39, the EPWMxSOCA and EPWMxSOCA signals are combined to generate four special signals that can be used to trigger an ADC start of conversion, and hence multiple modules can initiate an ADC start of conversion via the ADC trigger inputs.

The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in Figure 19-40) and can be configured to prescale these events before issuing an Interrupt request or an ADC start of conversion. The event-trigger prescaling logic can issue Interrupt requests and ADC start of conversion at:

- Every event
- Every second event
- Every third event

**Figure 19-39. Event-Trigger Submodule Inter-Connectivity of ADC Start of Conversion**

**Figure 19-40. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs**

The key registers used to configure the event-trigger submodule are shown in [Table 19-20](#).

**Table 19-20. Event-Trigger Submodule Registers**

| Register Name | Address offset | Shadowed | Description                      |
|---------------|----------------|----------|----------------------------------|
| ETSEL         | 0x0030         | No       | Event-trigger Selection Register |
| ETPS          | 0x0036         | No       | Event-trigger Prescale Register  |
| ETFLG         | 0x0034         | No       | Event-trigger Flag Register      |
| ETCLR         | 0x003A         | No       | Event-trigger Clear Register     |
| ETFRC         | 0x0038         | No       | Event-trigger Force Register     |

- ETSEL—This selects which of the possible events will trigger an interrupt or start an ADC conversion
- ETPS—This programs the event prescaling options mentioned above.
- ETFLG—These are flag bits indicating status of the selected and prescaled events.
- ETCLR—These bits allow you to clear the flag bits in the ETFLG register via software.
- ETFRC—These bits allow software forcing of an event. Useful for debugging or s/w intervention.

A more detailed look at how the various register bits interact with the Interrupt and ADC start of conversion logic are shown in [Figure 19-41](#), [Figure 19-42](#), and [Figure 19-43](#).

[Figure 19-41](#) shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt.
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

Which event can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCTR = 0x0000).
- Time-base counter equal to period (TBCTR = TBPRD).
- Time-base counter equal to zero or period (TBCTR = 0x0000 || TBCTR = TBPRD)
- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.

- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (ETPS[INTCNT]) register bits. That is, when the specified event occurs the ETPS[INTCNT] bits are incremented until they reach the value specified by ETPS[INTPRD]. When ETPS[INTCNT] = ETPS[INTPRD] the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the VIM.

When ETPS[INTCNT] reaches ETPS[INTPRD] the following behaviors will occur:

- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter will begin counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ETFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the ETFRC[INT] bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events will be detected and the ETFRC[INT] bit is also ignored.

The above definition means that you can generate an interrupt on every event, on every second event, or on every third event. An interrupt cannot be generated on every fourth or more events.

**Figure 19-41. Event-Trigger Interrupt Generator**

Figure 19-42 shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The ETPS[SOCACNT] counter and ETPS[SOCAPRD] period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag ETFLG[SOCA] is latched when a pulse is generated, but it does not stop further pulse generation. The enable/disable bit ETSEL[SOCAEN] stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that will trigger an SOCA and SOCB pulse can be configured separately in the ETSEL[SOCASEL] and ETSEL[SOCBSEL] bits. The possible events are the same events that can be specified for the interrupt generation logic with the addition of the DCAEVT1.soc and DCBEVT1.soc event signals from the digital compare (DC) submodule.

Figure 19-42. Event-Trigger SOCA Pulse Generator

- A The DCAEVT1.soc signals are signals generated by the Digital compare (DC) submodule described later in [Section 19.2.9](#).

Figure 19-43 shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.

Figure 19-43. Event-Trigger SOCB Pulse Generator

- A The DCBEVT1.soc signals are signals generated by the Digital compare (DC) submodule described later in [Section 19.2.9](#).

### 19.2.9 Digital Compare (DC) Submodule

Figure 19-44 illustrates where the digital compare (DC) submodule signals interface to other submodules in the ePWM system.

The digital compare (DC) submodule compares signals external to the ePWM module to directly generate PWM events/actions that then feed to the event-trigger, trip-zone, and time-base submodules. Additionally, blanking window functionality is supported to filter noise or unwanted pulses from the DC event signals.

Figure 19-44. Digital-Compare Submodule High-Level Block Diagram

#### 19.2.9.1 Purpose of the Digital Compare Submodule

The key functions of the digital compare submodule are:

- $\overline{TZ1}$ ,  $\overline{TZ2}$ , and  $\overline{TZ3}$  inputs generate Digital Compare A High/Low (DCAH, DCAL) and Digital Compare B High/Low (DCBH, DCBL) signals.
- DCAH/L and DCBH/L signals trigger events which can then either be filtered or fed directly to the trip-zone, event-trigger, and time-base submodules to:
  - generate a trip zone interrupt
  - generate an ADC start of conversion
  - force an event
  - generate a synchronization event for synchronizing the ePWM module TBCTR.
- Event filtering (blanking window logic) can optionally blank the input signal to remove noise.

### 19.2.9.2 Controlling and Monitoring the Digital Compare Submodule

The digital compare submodule operation is controlled and monitored through the following registers:

**Table 19-21. Digital Compare Submodule Registers**

| Register Name                         | Address offset | Shadowed | Description                                    |
|---------------------------------------|----------------|----------|------------------------------------------------|
| TZDCSEL <sup>(1)</sup> <sup>(2)</sup> | 0x0024         | No       | Trip Zone Digital Compare Select Register      |
| DCTRISEL <sup>(1)</sup>               | 0x0062         | No       | Digital Compare Trip Select Register           |
| DCACTL <sup>(1)</sup>                 | 0x0060         | No       | Digital Compare A Control Register             |
| DCBCTL <sup>(1)</sup>                 | 0x0066         | No       | Digital Compare B Control Register             |
| DCFCTL <sup>(1)</sup>                 | 0x0064         | No       | Digital Compare Filter Control Register        |
| DCCAPCTL <sup>(1)</sup>               | 0x006A         | No       | Digital Compare Capture Control Register       |
| DCFOFFSET                             | 0x0068         | Writes   | Digital Compare Filter Offset Register         |
| DCFOFFSETCNT                          | 0x006E         | No       | Digital Compare Filter Offset Counter Register |
| DCFWINDOW                             | 0x006C         | No       | Digital Compare Filter Window Register         |
| DCFWINDOWCNT                          | 0x0072         | No       | Digital Compare Filter Window Counter Register |
| DCCAP                                 | 0x0070         | Yes      | Digital Compare Counter Capture Register       |

<sup>(1)</sup> These registers are writable only in privileged mode.

<sup>(2)</sup> The TZDCSEL register is part of the trip-zone submodule but is mentioned again here because of its functional significance to the digital compare submodule.

### 19.2.9.3 Operation Highlights of the Digital Compare Submodule

The following sections describe the operational highlights and configuration options for the digital compare submodule.

#### 19.2.9.3.1 Digital Compare Events

As illustrated in [Figure 19-44](#), trip zone inputs ( $\overline{TZ1}$ ,  $\overline{TZ2}$ , and  $\overline{TZ3}$ ) can be selected via the DCTRISEL bits to generate the Digital Compare A High and Low (DCAH/L) and Digital Compare B High and Low (DCBH/L) signals. Then, the configuration of the TZDCSEL register qualifies the actions on the selected DCAH/L and DCBH/L signals, which generate the DCAEVT1/2 and DCBEVT1/2 events (Event Qualification A and B).

**NOTE:** The  $\overline{TZn}$  signals, when used as a DCEVT tripping functions, are treated as a normal input signal and can be defined to be active high or active low inputs. EPWM outputs are asynchronously tripped when either the  $\overline{TZn}$ , DCAEVTx.force, or DCBEVTx.force signals are active. For the condition to remain latched, a minimum of 3\*TBCLK sync pulse width is required. If pulse width is < 3\*TBCLK sync pulse width, the trip condition may or may not get latched by CBC or OST latches.

The DCAEVT1/2 and DCBEVT1/2 events can then be filtered to provide a filtered version of the event signals (DCEVTFILT) or the filtering can be bypassed. Filtering is discussed further in [Section 19.2.9.3.2](#). Either the DCAEVT1/2 and DCBEVT1/2 event signals or the filtered DCEVTFILT event signals can generate a force to the trip zone module, a TZ interrupt, an ADC SOC, or a PWM sync signal.

- **force signal:**

DCAEVT1/2.force signals force trip zone conditions which either directly influence the output on the EPWMxA pin (via TZCTL[DCAEVT1 or DCAEVT2] configurations) or, if the DCAEVT1/2 signals are selected as one-shot or cycle-by-cycle trip sources (via the TZSEL register), the DCAEVT1/2.force signals can effect the trip action via the TZCTL[TZA] configuration. The DCBEVT1/2.force signals behaves similarly, but affect the EPWMxB output pin instead of the EPWMxA output pin.

The priority of conflicting actions on the TZCTL register is as follows (highest priority overrides lower priority):

Output EPWMxA: TZA (highest) -> DCAEVT1 -> DCAEVT2 (lowest)

Output EPWMxB: TZB (highest) -> DCBEVT1 -> DCBEVT2 (lowest)

- **interrupt signal:**

DCAEVT1/2.interrupt signals generate trip zone interrupts to the VIM. To enable the interrupt, the user must set the DCAEVT1, DCAEVT2, DCBEVT1, or DCBEVT2 bits in the TZEINT register. Once one of these events occurs, an EPWMxTZINT interrupt is triggered, and the corresponding bit in the TZCLR register must be set in order to clear the interrupt.

- **soc signal:**

The DCAEVT1.soc signal interfaces with the event-trigger submodule and can be selected as an event which generates an ADC start-of-conversion-A (SOCA) pulse via the ETSEL[SOCASEL] bit. Likewise, the DCBEVT1.soc signal can be selected as an event which generates an ADC start-of-conversion-B (SOCB) pulse via the ETSEL[SOCBSEL] bit.

- **sync signal:**

The DCAEVT1.sync and DCBEVT1.sync events are ORed with the EPWMxSYNCl input signal and the TBCTL[SWFSYNC] signal to generate a synchronization pulse to the time-base counter.

[Figure 19-45](#) and [Figure 19-46](#) show how the DCAEVT1, DCAEVT2 or DCEVTFILT signals are processed to generate the digital compare A event force, interrupt, soc and sync signals.

**Figure 19-45. DCAEVT1 Event Triggering**

Figure 19-48. DCBEVT2 Event Triggering

### 19.2.9.3.2 Event Filtering

The DCAEVT1/2 and DCBEVT1/2 events can be filtered via event filtering logic to remove noise by optionally blanking events for a certain period of time. This is useful for cases where the analog comparator outputs may be selected to trigger DCAEVT1/2 and DCBEVT1/2 events, and the blanking logic is used to filter out potential noise on the signal prior to tripping the PWM outputs or generating an interrupt or ADC start-of-conversion. The event filtering can also capture the TBCTR value of the trip event. The diagram below shows the details of the event filtering logic.

If the blanking logic is enabled, one of the digital compare events – DCAEVT1, DCAEVT2, DCBEVT1, DCBEVT2 – is selected for filtering. The blanking window, which filters out all event occurrences on the signal while it is active, will be aligned to either a CTR = PRD pulse or a CTR = 0 pulse (configured by the DCFCTL[PULSESEL] bits). An offset value in TBCLK counts is programmed into the DCFOFFSET register, which determines at what point after the CTR = PRD or CTR = 0 pulse the blanking window starts. The duration of the blanking window, in number of TBCLK counts after the offset counter expires, is written to the DCFWINDOW register by the application. During the blanking window, all events are ignored. Before and after the blanking window ends, events can generate soc, sync, interrupt, and force signals as before.

Figure 19-50 illustrates several timing conditions for the offset and blanking window within an ePWM period. Notice that if the blanking window crosses the CTR = 0 or CTR = PRD boundary, the next window still starts at the same offset value after the CTR = 0 or CTR = PRD pulse.

**Figure 19-49. Event Filtering**

**Figure 19-50. Blanking Window Timing Diagram**

### **19.2.10 Proper Interrupt Initialization Procedure**

When the ePWM peripheral clock is enabled it may be possible that interrupt flags may be set due to spurious events due to the ePWM registers not being properly initialized. The proper procedure for initializing the ePWM peripheral is as follows:

1. Disable global interrupts (CPU INTM flag)
2. Disable ePWM interrupts
3. Set TBCLKSYNC=0
4. Initialize peripheral registers
5. Set TBCLKSYNC=1
6. Clear any spurious ePWM flags (including interrupt flags)
7. Enable ePWM interrupts
8. Enable global interrupts

## 19.3 Application Examples

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

### 19.3.1 Overview of Multiple Modules

Previously in this user's guide, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in [Figure 19-51](#). This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

**Figure 19-51. Simplified ePWM Module**

### 19.3.2 Key Configuration Capabilities

The key configuration choices available to each module are as follows:

- Options for SyncIn
  - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
  - Do nothing or ignore incoming sync strobe—enable switch open
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)

For each choice of SyncOut, a module may also choose to load its own counter with a new phase value on a SyncIn strobe input or choose to ignore it, that is, via the enable switch. Although various combinations are possible, the two most common—master module and slave module modes—are shown in [Figure 19-52](#).

**Figure 19-52. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave**

### 19.3.3 Controlling Multiple Buck Converters With Independent Frequencies

One of the simplest power converter topologies is the buck. A single ePWM module configured as a master can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. [Figure 19-53](#) shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Masters and no synchronization is used. [Figure 19-54](#) shows the waveforms generated by the setup shown in [Figure 19-53](#); note that only three waveforms are shown, although there are four stages.

**Figure 19-53. Control of Four Buck Stages. Here  $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$**

NOTE:  $\Phi = X$  indicates value in phase register is a "don't care"

**Figure 19-54. Buck Waveforms for Figure 19-53 (Note: Only three bucks shown here)**

**Example 19-8. Configuration for Example in Figure 19-54**

```
//=====
// (Note: code for only 3 modules shown)
// Initialization Time
//=====
// EPWM Module 1 config
EPwm1Regs.TBPRD = 1200; // Period = 1201 TBCLK counts
EPwm1Regs.TBPHS.half.TBPHS = 0; // Set Phase register to zero
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP; // Asymmetrical mode
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Phase loading disabled
EPwm1Regs.TBCTL.bit.PRDL = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCSEL = TB_SYNC_DISABLE;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR=Zero
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on CTR=Zero
EPwm1Regs.AQCTLA.bit.PRDL = AQ_CLEAR;
EPwm1Regs.AQCTLA.bit.CAU = AQ_SET;
// EPWM Module 2 config
EPwm2Regs.TBPRD = 1400; // Period = 1401 TBCLK counts
EPwm2Regs.TBPHS.half.TBPHS = 0; // Set Phase register to zero
EPwm2Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP; // Asymmetrical mode
EPwm2Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Phase loading disabled
EPwm2Regs.TBCTL.bit.PRDL = TB_SHADOW;
EPwm2Regs.TBCTL.bit.SYNCSEL = TB_SYNC_DISABLE;
EPwm2Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm2Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm2Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR=Zero
EPwm2Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on CTR=Zero
EPwm2Regs.AQCTLA.bit.PRDL = AQ_CLEAR;
EPwm2Regs.AQCTLA.bit.CAU = AQ_SET;
// EPWM Module 3 config
EPwm3Regs.TBPRD = 800; // Period = 801 TBCLK counts
EPwm3Regs.TBPHS.half.TBPHS = 0; // Set Phase register to zero
EPwm3Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm3Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Phase loading disabled
EPwm3Regs.TBCTL.bit.PRDL = TB_SHADOW;
EPwm3Regs.TBCTL.bit.SYNCSEL = TB_SYNC_DISABLE;
EPwm3Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm3Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm3Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR=Zero
EPwm3Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on CTR=Zero
EPwm3Regs.AQCTLA.bit.PRDL = AQ_CLEAR;
EPwm3Regs.AQCTLA.bit.CAU = AQ_SET;
//
// Run Time (Note: Example execution of one run-time instant)
//=====
EPwm1Regs.CMPA.half.CMPA = 700; // adjust duty for output EPWM1A
EPwm2Regs.CMPA.half.CMPA = 700; // adjust duty for output EPWM2A
EPwm3Regs.CMPA.half.CMPA = 500; // adjust duty for output EPWM3A
```

### 19.3.4 Controlling Multiple Buck Converters With Same Frequencies

If synchronization is a requirement, ePWM module 2 can be configured as a slave and can operate at integer multiple (N) frequencies of module 1. The sync signal from master to slave ensures these modules remain locked. Figure 19-55 shows such a configuration; Figure 19-56 shows the waveforms generated by the configuration.

**Figure 19-55. Control of Four Buck Stages. (Note:  $F_{PWM2} = N \times F_{PWM1}$ )**

Figure 19-56. Buck Waveforms for Figure 19-55 (Note:  $F_{PWM2} = F_{PWM1}$ )

**Example 19-9. Code Snippet for Configuration in Figure 19-55**

```
//=====
// EPWM Module 1 config
    EPwm1Regs.TBPRD = 600;                // Period = 1200 TBCLK counts
    EPwm1Regs.TBPHS.half.TBPHS = 0;      // Set Phase register to zero
    EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UPDOWN; // Symmetrical mode
    EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Master module
    EPwm1Regs.TBCTL.bit.PRDL = TB_SHADOW;
    EPwm1Regs.TBCTL.bit.SYNCSEL = TB_CTR_ZERO; // Sync down-stream module
    EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
    EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
    EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR=Zero
    EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on CTR=Zero
    EPwm1Regs.AQCTLA.bit.CAU = AQ_SET;    // set actions for EPWM1A
    EPwm1Regs.AQCTLA.bit.CAD = AQ_CLEAR;
    EPwm1Regs.AQCTLB.bit.CBU = AQ_SET;    // set actions for EPWM1B
    EPwm1Regs.AQCTLB.bit.CBD = AQ_CLEAR;
// EPWM Module 2 config
    EPwm2Regs.TBPRD = 600;                // Period = 1200 TBCLK counts
    EPwm2Regs.TBPHS.half.TBPHS = 0;      // Set Phase register to zero
    EPwm2Regs.TBCTL.bit.CTRMODE = TB_COUNT_UPDOWN; // Symmetrical mode
    EPwm2Regs.TBCTL.bit.PHSEN = TB_ENABLE; // Slave module
    EPwm2Regs.TBCTL.bit.PRDL = TB_SHADOW;
    EPwm2Regs.TBCTL.bit.SYNCSEL = TB_SYNC_IN; // sync flow-through
    EPwm2Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
    EPwm2Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
    EPwm2Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR=Zero
    EPwm2Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on CTR=Zero
    EPwm2Regs.AQCTLA.bit.CAU = AQ_SET;    // set actions for EPWM2A
    EPwm2Regs.AQCTLA.bit.CAD = AQ_CLEAR;
    EPwm2Regs.AQCTLB.bit.CBU = AQ_SET;    // set actions for EPWM2B
    EPwm2Regs.AQCTLB.bit.CBD = AQ_CLEAR;
//
// Run Time (Note: Example execution of one run-time instance)
//=====
    EPwm1Regs.CMPA.half.CMPA = 400;      // adjust duty for output EPWM1A
    EPwm1Regs.CMPB = 200;                // adjust duty for output EPWM1B
    EPwm2Regs.CMPA.half.CMPA = 500;      // adjust duty for output EPWM2A
    EPwm2Regs.CMPB = 300;                // adjust duty for output EPWM2B
```

**Figure 19-58. Half-H Bridge Waveforms for Figure 19-57 (Note: Here  $F_{PWM2} = F_{PWM1}$  )**

**Example 19-10. Code Snippet for Configuration in Figure 19-57**

```
//=====

### 19.3.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase Inverter case. In such a case, six switching elements can be controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A master + two slaves configuration can easily address this requirement. [Figure 19-59](#) shows how six PWM modules can control two independent 3-phase Inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are masters as in [Figure 19-59](#)), or both inverters can be synchronized by using one master (module 1) and five slaves. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, 3 (also all equal).

**Figure 19-59. Control of Dual 3-Phase Inverter Stages as Is Commonly Used in Motor Control**

Figure 19-60. 3-Phase Inverter Waveforms for Figure 19-59 (Only One Inverter Shown)

### 19.3.7 Practical Applications Using Phase Control Between PWM Modules

So far, none of the examples have made use of the phase register (TBPHS). It has either been set to zero or its value has been a don't care. However, by programming appropriate values into TBPHS, multiple PWM modules can address another class of applications that rely on phase relationship between stages for correct operation. As described in the TB module section, a PWM module can be configured to allow a SyncIn pulse to cause the TBPHS register to be loaded into the TBCTR register. To illustrate this concept, [Figure 19-61](#) shows a master and slave module with a phase relationship of 120°, that is, the slave leads the master.

**Figure 19-61. Configuring Two PWM Modules for Phase Control**

[Figure 19-62](#) shows the associated timing waveforms for this configuration. Here, TBPRD = 600 for both master and slave. For the slave, TBPHS = 200 (that is,  $200/600 \times 360^\circ = 120^\circ$ ). Whenever the master generates a SyncIn pulse (CTR = PRD), the value of TBPHS = 200 is loaded into the slave TBCTR register so the slave time-base is always leading the master's time-base by 120°.

**Figure 19-62. Timing Waveforms Associated With Phase Control Between 2 Modules**

## 19.4 EPWM Registers

Table 19-22 lists the memory-mapped registers for the EPWM. All register offset addresses not listed in Table 19-22 should be considered as reserved locations and the register contents should not be modified.

**Table 19-22. EPWM REGISTERS**

These bits select the source of the EPWMxSYNCO signal.<br>0h = EPWMxSYNCO<br>1h = CTR = zero: Time-base counter equal to zero (TBCTR = 0x0000)<br>2h = CTR = CMPB : Time-base counter equal to counter-compare B (TBCTR = CMPB)<br>3h = Disable EPWMxSYNCO signal                                                                                                                                                                                                                  |
| 3   | PRDLD     | R/W  | 0h    | Active Period Register Load From Shadow Register Select<br>0h = The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCTR, is equal to 0. A write or read to the TBPRD register accesses the shadow register.<br>1h = Load the TBPRD register immediately without using a shadow register. A write or read to the TBPRD register directly accesses the active register.                                                                                                    |
| 2   | PHSEN     | R/W  | 0h    | Counter Register Load From Phase Register Enable<br>0h = Do not load the time-base counter (TBCTR) from the time-base phase register (TBPHS)<br>1h = Load the time-base counter with the phase register when an EPWMxSYNCl input signal occurs or when a software synchronization is forced by the SWFSYNC bit, or when a digital compare sync event occurs.                                                                                                                                                      |
| 1-0 | CTRMODE   | R/W  | 3h    | Counter Mode. The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change.<br>These bits set the time-base counter mode of operation as follows:<br>0h = Up-count mode<br>1h = Down-count mode<br>2h = Up-down-count mode<br>3h = Stop-freeze counter operation (default on reset) |

### 19.4.3 TBPHS Register (offset = 4h) [reset = 0h]

TBPHS is shown in [Figure 19-65](#) and described in [Table 19-25](#).

**Figure 19-65. TBPHS Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 19-25. TBPHS Register Field Descriptions**

| Bit  | Field | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|-------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | TBPHS | R/W  | 0h    | These bits set time-base counter phase of the selected ePWM relative to the time-base that is supplying the synchronization input signal. Valid values: 0-FFFFh<br>If TBCTL[PHSEN] = 0, then the synchronization event is ignored and the time-base counter is not loaded with the phase.<br>If TBCTL[PHSEN] = 1, then the time-base counter (TBCTR) will be loaded with the phase (TBPHS) when a synchronization event occurs. The synchronization event can be initiated by the input synchronization signal (EPWMxSYNCl) or by a software forced synchronization. |

### 19.4.4 TBPRD Register (offset = 8h) [reset = 0h]

TBPRD is shown in [Figure 19-66](#) and described in [Table 19-26](#).

**Figure 19-66. TBPRD Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 19-26. TBPRD Register Field Descriptions**

| Bit  | Field | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------|-------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | TBPRD | R/W  | 0h    | <p>These bits determine the period of the time-base counter. This sets the PWM frequency. Valid values: 0-FFFFh</p> <p>Shadowing of this register is enabled and disabled by the TBCTL[PRDL] bit. By default this register is shadowed.</p> <p>If TBCTL[PRDL] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the time-base counter equals 0.</p> <p>If TBCTL[PRDL] = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.</p> <p>The active and shadow registers share the same memory map address.</p> |

### 19.4.5 TBCTR Register (offset = Ah) [reset = 0h]

TBCTR is shown in [Figure 19-67](#) and described in [Table 19-27](#).

**Figure 19-67. TBCTR Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 19-27. TBCTR Register Field Descriptions**

| Bit  | Field | Type | Reset | Description                                                                                                                                                                                                                                                                                           |
|------|-------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | TBCTR | R/W  | 0h    | Reading these bits gives the current time-base counter value. Valid values: 0-FFFFh<br>Writing to these bits sets the current time-base counter value. The update happens as soon as the write occurs. The write is NOT synchronized to the time-base clock (TBCLK) and the register is not shadowed. |

### 19.4.6 CMPCTL Register (offset = Ch) [reset = 0h]

CMPCTL is shown in [Figure 19-68](#) and described in [Table 19-28](#).

**Figure 19-68. CMPCTL Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 19-28. CMPCTL Register Field Descriptions**

| Bit   | Field     | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |

### 19.4.7 CMPA Register (offset = 10h) [reset = 0h]

CMPA is shown in [Figure 19-69](#) and described in [Table 19-29](#).

**Figure 19-69. CMPA Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 19-29. CMPA Register Field Descriptions**

| Bit  | Field | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------|-------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | CMPA  | R/W  | 0h    | <p>The value in the active CMPA register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:</p> <p>Do nothing, the event is ignored.</p> <p>Clear: Pull the EPWMxA and/or EPWMxB signal low</p> <p>Set: Pull the EPWMxA and/or EPWMxB signal high</p> <p>Toggle the EPWMxA and/or EPWMxB signal</p> <p>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed. If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register. Before a write, the CMPCTL[SHDWAFULL] bit can be read to determine if the shadow register is currently full. If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. In either mode, the active and shadow registers share the same memory map address.</p> |

### 19.4.8 AQCTLA Register (offset = 14h) [reset = 0h]

AQCTLA is shown in [Figure 19-70](#) and described in [Table 19-30](#).

### 19.4.9 CMPB Register (offset = 16h) [reset = 0h]

CMPB is shown in [Figure 19-71](#) and described in [Table 19-31](#).

**Figure 19-71. CMPB Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 19-31. CMPB Register Field Descriptions**

| Bit  | Field | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------|-------|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | CMPB  | R/W  | 0h    | <p>The value in the active CMPB register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare B" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:</p> <p>Do nothing, event is ignored.</p> <p>Clear: Pull the EPWMxA and/or EPWMxB signal low</p> <p>Set: Pull the EPWMxA and/or EPWMxB signal high</p> <p>Toggle the EPWMxA and/or EPWMxB signal</p> <p>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWBMODE] bit. By default this register is shadowed. If CMPCTL[SHDWBMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADBMODE] bit field determines which event will load the active register from the shadow register. Before a write, the CMPCTL[SHDWBFULL] bit can be read to determine if the shadow register is currently full. If CMPCTL[SHDWBMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. In either mode, the active and shadow registers share the same memory map address.</p> |

### 19.4.10 AQSFRFC Register (offset = 18h) [reset = 0h]

AQSFRFC is shown in [Figure 19-72](#) and described in [Table 19-32](#).

|-----|----------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1-0 | OUT_MODE | R/W  | 0h    | <p>Dead-band Output Mode Control. Bit 1 controls the S1 switch and bit 0 controls the S0 switch shown in <a href="#">Figure 19-28</a>.</p> <p>This allows you to selectively enable or bypass the dead-band generation for the falling-edge and rising-edge delay.</p> <p>0h = Dead-band generation is bypassed for both output signals. In this mode, both the EPWMxA and EPWMxB output signals from the action-qualifier are passed directly to the PWM-chopper submodule. In this mode, the POLSEL and IN_MODE bits have no effect.</p> <p>1h = Disable rising-edge delay. The EPWMxA signal from the action-qualifier is passed straight through to the EPWMxA input of the PWM-chopper submodule. The falling-edge delayed signal is seen on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE].</p> <p>2h = The rising-edge delayed signal is seen on output EPWMxA. The input signal for the delay is determined by DBCTL[IN_MODE]. Disable falling-edge delay. The EPWMxB signal from the action-qualifier is passed straight through to the EPWMxB input of the PWM-chopper submodule.</p> <p>3h = Dead-band is fully enabled for both rising-edge delay on output EPWMxA and falling-edge delay on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE].</p> |

### 19.4.13 AQCSFRC Register (offset = 1Eh) [reset = 0h]

AQCSFRC is shown in [Figure 19-75](#) and described in [Table 19-35](#).

**Figure 19-75. AQCSFRC Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 19-35. AQCSFRC Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| 2    | OST      | R    | 0h    | Latched Status Flag for A One-Shot Trip Event. This bit is cleared by writing the appropriate value to the TZCLR register.<br>0h = No one-shot trip event has occurred.<br>1h = Indicates a trip event has occurred on a pin selected as a one-shot trip source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 1    | CBC      | R    | 0h    | Latched Status Flag for Cycle-By-Cycle Trip Event. This bit is cleared by writing the appropriate value to the TZCLR register.<br>0h = No cycle-by-cycle trip event has occurred.<br>1h = Indicates a trip event has occurred on a signal selected as a cycle-by-cycle trip source. The TZFLG.CBC bit will remain set until it is manually cleared by the user. If the cycle-by-cycle trip event is still present when the CBC bit is cleared, then CBC will be immediately set again. The specified condition on the signal is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x0000) if the trip condition is no longer present. The condition on the signal is only cleared when the TBCTR = 0x0000 no matter where in the cycle the CBC flag is cleared. |
| 0    | INT      | R    | 0h    | Latched Trip Interrupt Status Flag. No further EPWMx_TZINT VIM interrupts will be generated until this flag is cleared. If the interrupt flag is cleared when either CBC or OST is set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts. This bit is cleared by writing the appropriate value to the TZCLR register.<br>0h = Indicates no interrupt has been generated.<br>1h = Indicates an EPWMx_TZINT VIM interrupt was generated because of a trip condition.                                                                                                                                                                                                                                                                  |

### 19.4.22 ETSEL Register (offset = 30h) [reset = 0h]

ETSEL is shown in [Figure 19-84](#) and described in [Table 19-44](#).

## Enhanced Capture (eCAP) Module

The enhanced Capture (eCAP) module is essential in systems where accurate timing of external events is important. This microcontroller implements 6 instances of the eCAP module.

| Topic                                      | Page |

| 20.6 Application of the ECAP Module .....  | 846  |
| 20.7 Application of the APWM Mode .....    | 855  |

## 20.1 Introduction

Uses for eCAP include:

- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

The eCAP module described in this guide includes the following features:

- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single shot capture of up to four event time-stamps
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the ECAP module can be configured as a single channel PWM output

## 20.2 Description

In the context of this chapter, one eCAP channel has the following independent key resources:

- Dedicated input capture pin
- 32-bit time base (counter)
- 4 x 32-bit time-stamp capture registers (CAP1-CAP4)
- 4-stage sequencer (Modulo4 counter) that is synchronized to external events, ECAP pin rising/falling edges
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Input capture signal prescaling (from 2-62)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Control for continuous time-stamp captures using a 4-deep circular buffer (CAP1-CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

## 20.3 Capture and APWM Operating Mode

You can use the eCAP module resources to implement a single-channel PWM generator (with 32 bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and capture shadow registers, respectively. Figure 20-1 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

**Figure 20-1. Capture and APWM Modes of Operation**

- A A single pin is shared between CAP and APWM functions. In capture mode, it is an input; in APWM mode, it is an output.
- B In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

## 20.4 Capture Mode Description

Figure 20-2 shows the various components that implement the capture function.

**Figure 20-2. Capture Function Diagram**

### 20.4.1 Event Prescaler

- An input capture signal (pulse train) can be prescaled by  $N = 2-62$  (in multiples of 2) or can bypass the prescaler.

This is useful when very high frequency signals are used as inputs. [Figure 20-3](#) shows a functional diagram and [Figure 20-4](#) shows the operation of the prescale function.

**Figure 20-3. Event Prescale Control**

- A When a prescale value of 1 is chosen (that is,  $ECCTL1[13:9] = 0,0,0,0,0$ ) the input capture signal by-passes the prescale logic completely.

**Figure 20-4. Prescale Function Waveforms**

### 20.4.2 Edge Polarity Select and Qualifier

- Four independent edge polarity (rising edge/falling edge) selection MUXes are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to its respective CAPx register by the Mod4 counter. The CAPx register is loaded on the falling edge.

### 20.4.3 Continuous/One-Shot Control

- The Mod4 (2 bit) counter is incremented via edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output, and when equal stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. This occurs during one-shot operation.

The continuous/one-shot block controls the start/stop and reset (zero) functions of the Mod4 counter via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (that is, time-stamps).

Re-arming prepares the eCAP module for another capture sequence. Also re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

**Figure 20-5. Details of the Continuous/One-shot Block**

### 20.4.4 32-Bit Counter and Phase Control

This counter provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1-LD4 signals.

**Figure 20-6. Details of the Counter and Synchronization Block**

### 20.4.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (that is, capture a time-stamp) when their respective LD inputs are strobed.

Loading of the capture registers can be inhibited via control bit CAPLDEN. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, that is, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

CAP3 and CAP4 registers become the respective shadow registers (APRD and ACMP) for CAP1 and CAP2 during APWM operation.

### 20.4.6 Interrupt Control

An Interrupt can be generated on capture events (CEVT1-CEVT4, CTROVF) or APWM events (CTR = PRD, CTR = CMP).

A counter overflow event (FFFFFFFF->00000000) is also provided as an interrupt source (CTROVF).

The capture events are edge and sequencer qualified (that is, ordered in time) by the polarity select and Mod4 gating, respectively.

One of these events can be selected as the interrupt source (from the eCAPx module) going to the PIE.

Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CTR=PRD, CTR=CMP) can be generated. The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the PIE only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (ECCLR) before any other interrupt pulses are generated. You can force an interrupt event via the interrupt force register (ECFRC). This is useful for test purposes.

**Note:** The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP/APWM == 0]). The CTR=PRD, CTR=CMPEQ flags are only valid in APWM mode (ECCTL2[CAP/APWM == 1]). CNTOVF flag is valid in both modes.

**Figure 20-7. Interrupts in eCAP Module**

### 20.4.7 Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal, that is, CTR[31:0] = PRD[31:0]

## 20.4.8 APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers either immediately upon a write, or on a CTR = PRD trigger.
- In APWM mode, writing to CAP1/CAP2 active registers will also write the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 will invoke the shadow mode.
- During initialization, you must write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates, that is, during run-time, you only need to use the shadow registers.

**Figure 20-8. PWM Waveform Details Of APWM Mode Operation**

The behavior of APWM active high mode (APWMPOL == 0) is as follows:

CMP = 0x00000000, output low for duration of period (0% duty)

CMP = 0x00000001, output high 1 cycle

CMP = 0x00000002, output high 2 cycles

CMP = PERIOD, output high except for 1 cycle (<100% duty)

CMP = PERIOD+1, output high for complete period (100% duty)

CMP > PERIOD+1, output high for complete period

The behavior of APWM active low mode (APWMPOL == 1) is as follows:

CMP = 0x00000000, output high for duration of period (0% duty)

CMP = 0x00000001, output low 1 cycle

CMP = 0x00000002, output low 2 cycles

CMP = PERIOD, output low except for 1 cycle (<100% duty)

CMP = PERIOD+1, output low for complete period (100% duty)

CMP > PERIOD+1, output low for complete period

## 20.5 ECAP Registers

[Table 20-1](#) lists the memory-mapped registers for the ECAP. All register offset addresses not listed in [Table 20-1](#) should be considered as reserved locations and the register contents should not be modified.

**Table 20-1. ECAP REGISTERS**

| Offset | Acronym | Register Name                       | Section                         |

### 20.5.1 TSCTR Register (offset = 0h) [reset = 0h]

TSCTR is shown in [Figure 20-9](#) and described in [Table 20-2](#).

**Figure 20-9. TSCTR Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 20-2. TSCTR Register Field Descriptions**

| Bit  | Field | Type | Reset | Description                                                           |
|------|-------|------|-------|-----------------------------------------------------------------------|
| 31-0 | TSCTR | R/W  | 0h    | Active 32-bit counter register that is used as the capture time-base. |

## 20.5.2 CTRPHS Register (offset = 4h) [reset = 0h]

CTRPHS is shown in [Figure 20-10](#) and described in [Table 20-3](#).

**Figure 20-10. CTRPHS Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 20-3. CTRPHS Register Field Descriptions**

| Bit  | Field  | Type | Reset | Description                                                                                                                                                                                                                                                                          |
|------|--------|------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CTRPHS | R/W  | 0h    | Counter phase value register that can be programmed for phase lag/lead. This register shadows TSCTR and is loaded into TSCTR upon either a SYNCI event or S/W force via a control bit. Used to achieve phase control synchronization with respect to other eCAP and ePWM time-bases. |

### 20.5.3 CAP1 Register (offset = 8h) [reset = 0h]

CAP1 is shown in [Figure 20-11](#) and described in [Table 20-4](#).

**Figure 20-11. CAP1 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 20-4. CAP1 Register Field Descriptions**

| Bit  | Field | Type | Reset | Description                                                                                                                                                                                                          |
|------|-------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CAP1  | R/W  | 0h    | This register can be loaded (written) by:<br>Time-Stamp (that is, counter value) during a capture event<br>Software - may be useful for test purposes<br>APRD shadow register (that is, CAP4) when used in APWM mode |

### 20.5.4 CAP2 Register (offset = Ch) [reset = 0h]

CAP2 is shown in [Figure 20-12](#) and described in [Table 20-5](#).

In APWM mode, writing to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

**Figure 20-12. CAP2 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 20-5. CAP2 Register Field Descriptions**

| Bit  | Field | Type | Reset | Description                                                                                                                                                                                                          |
|------|-------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CAP2  | R/W  | 0h    | This register can be loaded (written) by:<br>Time-Stamp (that is, counter value) during a capture event<br>Software - may be useful for test purposes<br>APRD shadow register (that is, CAP4) when used in APWM mode |

### 20.5.5 CAP3 Register (offset = 10h) [reset = 0h]

CAP3 is shown in [Figure 20-13](#) and described in [Table 20-6](#).

**Figure 20-13. CAP3 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 20-6. CAP3 Register Field Descriptions**

| Bit  | Field | Type | Reset | Description                                                                                                                                                                                                 |
|------|-------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CAP3  | R/W  | 0h    | In CMP mode, this is a time-stamp capture register. In APWM mode, this is the period shadow (APRD) register. You update the PWM period value through this register. In this mode, CAP3 (APRD) shadows CAP1. |

### 20.5.6 CAP4 Register (offset = 14h) [reset = 0h]

CAP4 is shown in [Figure 20-14](#) and described in [Table 20-7](#).

**Figure 20-14. CAP4 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 20-7. CAP4 Register Field Descriptions**

| Bit  | Field | Type | Reset | Description                                                                                                                                                                                               |
|------|-------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CAP4  | R/W  | 0h    | In CMP mode, this is a time-stamp capture register. In APWM mode, this is the compare shadow (ACMP) register. You update the PWM compare value via this register. In this mode, CAP4 (ACMP) shadows CAP2. |

### 20.5.7 ECCTL2 Register (offset = 28h) [reset = 2h]

ECCTL2 is shown in [Figure 20-15](#) and described in [Table 20-8](#).

**Figure 20-15. ECCTL2 Register**

|           |    |          |           |        |           |          |             |

## 20.5.10 ECEINT Register (offset = 2Eh) [reset = 0h]

ECEINT is shown in Figure 20-18 and described in Table 20-11.

The interrupt enable bits (CEVT1, ...) block any of the selected events from generating an interrupt. Events will still be latched into the flag bit (ECFLG register) and can be forced/cleared via the ECFRC/ECCLR registers. The proper procedure for configuring peripheral modes and interrupts is as follows:

**Figure 20-18. ECEINT Register**

## 20.6 Application of the ECAP Module

The following sections will provide applications examples and code snippets to show how to configure and operate the eCAP module. For clarity and ease of use, the examples use the eCAP “C” header files. Below are useful #defines which will help in the understanding of the examples.

```
// ECCTL1 ( ECAP Control Reg 1)
//=====
// CAPxPOL bits
#define EC_RISING 0x0
#define EC_FALLING 0x1
// CTRRSTx bits
#define EC_ABS_MODE 0x0
#define EC_DELTA_MODE 0x1
// PRESCALE bits
#define EC_BYPASS 0x0
#define EC_DIV1 0x0
#define EC_DIV2 0x1
#define EC_DIV4 0x2
#define EC_DIV6 0x3
#define EC_DIV8 0x4
#define EC_DIV10 0x5
// ECCTL2 ( ECAP Control Reg 2)
//=====
// CONT/ONESHOT bit
#define EC_CONTINUOUS 0x0
#define EC_ONESHOT 0x1
// STOPVALUE bit
#define EC_EVENT1 0x0
#define EC_EVENT2 0x1
#define EC_EVENT3 0x2
#define EC_EVENT4 0x3
// RE-ARM bit
#define EC_ARM 0x1
// TSCTRSTOP bit
#define EC_FREEZE 0x0
#define EC_RUN 0x1
// SYNC0_SEL bit
#define EC_SYNCIN 0x0
#define EC_CTR_PRD 0x1
#define EC_SYNC0_DIS 0x2
// CAP/APWM mode bit
#define EC_CAP_MODE 0x0
#define EC_APWM_MODE 0x1
// APWMPOL bit
#define EC_ACTV_HI 0x0
#define EC_ACTV_LO 0x1
// Generic
#define EC_DISABLE 0x0
#define EC_ENABLE 0x1
#define EC_FORCE 0x1
```

### 20.6.1 Example 1 - Absolute Time-Stamp Operation Rising Edge Trigger

Figure 20-21 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (that is, time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFF FFFFh (that is, maximum value), it wraps around to 0000 0000h (not shown in Figure 20-21), if this occurs, the CTROVF (counter overflow) flag is set, and an interrupt (if enabled) occurs, CTROVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. Captured Time-stamps are valid at the point indicated by the diagram, that is, after the 4th event, hence event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPx registers.

**Figure 20-21. Capture Sequence for Absolute Time-stamp and Rising Edge Detect**

### 20.6.1.1 Code snippet for CAP mode Absolute Time, Rising Edge Trigger

```
// Code snippet for CAP mode Absolute Time, Rising edge trigger
// Initialization Time
//=====
// ECAP module 1 config
ECap1Regs.ECCTL1.bit.CAP1POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP2POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP3POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP4POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CTRRST1 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CTRRST2 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CTRRST3 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CTRRST4 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CAPLDEN = EC_ENABLE;
ECap1Regs.ECCTL1.bit.PRESCALE = EC_DIV1;
ECap1Regs.ECCTL2.bit.CAP_APWM = EC_CAP_MODE;
ECap1Regs.ECCTL2.bit.CONT_ONESHT = EC_CONTINUOUS;
ECap1Regs.ECCTL2.bit.SYNCO_SEL = EC_SYNCO_DIS;
ECap1Regs.ECCTL2.bit.SYNCI_EN = EC_DISABLE;
ECap1Regs.ECCTL2.bit.TSCTRSTOP = EC_RUN; // Allow TSCTR to run
// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECap1Regs.CAP1; // Fetch Time-Stamp captured at t1
TSt2 = ECap1Regs.CAP2; // Fetch Time-Stamp captured at t2
TSt3 = ECap1Regs.CAP3; // Fetch Time-Stamp captured at t3
TSt4 = ECap1Regs.CAP4; // Fetch Time-Stamp captured at t4
Period1 = TSt2-TSt1; // Calculate 1st period
Period2 = TSt3-TSt2; // Calculate 2nd period
Period3 = TSt4-TSt3; // Calculate 3rd period
```

## 20.6.2 Example 2 - Absolute Time-Stamp Operation Rising and Falling Edge Trigger

In Figure 20-22 the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is,  $\text{Period1} = t_3 - t_1$ ,  $\text{Period2} = t_5 - t_3$ , and so on;  $\text{Duty Cycle1 (on-time \%)} = (t_2 - t_1) / \text{Period1} \times 100\%$ , and so on;  $\text{Duty Cycle1 (off-time \%)} = (t_3 - t_2) / \text{Period1} \times 100\%$ , and so on.

**Figure 20-22. Capture Sequence for Absolute Time-stamp With Rising and Falling Edge Detect**

### 20.6.2.1 Code snippet for CAP mode Absolute Time, Rising & Falling Edge Triggers

```
// Code snippet for CAP mode Absolute Time, Rising & Falling edge triggers
// Initialization Time
//=====
// ECAP module 1 config
ECap1Regs.ECCTL1.bit.CAP1POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP2POL = EC_FALLING;
ECap1Regs.ECCTL1.bit.CAP3POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP4POL = EC_FALLING;
ECap1Regs.ECCTL1.bit.CTRRST1 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CTRRST2 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CTRRST3 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CTRRST4 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CAPLDEN = EC_ENABLE;
ECap1Regs.ECCTL1.bit.PRESCALE = EC_DIV1;
ECap1Regs.ECCTL2.bit.CAP_APWM = EC_CAP_MODE;
ECap1Regs.ECCTL2.bit.CONT_ONESHT = EC_CONTINUOUS;
ECap1Regs.ECCTL2.bit.SYNCO_SEL = EC_SYNCO_DIS;
ECap1Regs.ECCTL2.bit.SYNCI_EN = EC_DISABLE;
ECap1Regs.ECCTL2.bit.TSCTRSTOP = EC_RUN; // Allow TSCTR to run
// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECap1Regs.CAP1; // Fetch Time-Stamp captured at t1
TSt2 = ECap1Regs.CAP2; // Fetch Time-Stamp captured at t2
TSt3 = ECap1Regs.CAP3; // Fetch Time-Stamp captured at t3
TSt4 = ECap1Regs.CAP4; // Fetch Time-Stamp captured at t4
Period1 = TSt3-TSt1; // Calculate 1st period
DutyOnTime1 = TSt2-TSt1; // Calculate On time
DutyOffTime1 = TSt3-TSt2; // Calculate Off time
```

### 20.6.3 Example 3 - Time Difference (Delta) Operation Rising Edge Trigger

This example Figure 20-23 shows how the eCAP module can be used to collect Delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is Reset back to Zero on every valid event. Here Capture events are qualified as Rising edge only. On an event, TSCTR contents (that is, time-stamp) is captured first, and then TSCTR is reset to Zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFF FFFFh (that is, maximum value), before the next event, it wraps around to 0000 0000h and continues, a CINTOVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. The advantage of Delta-time Mode is that the CAPx contents directly give timing data without the need for CPU calculations, that is, Period1 =  $T_1$ , Period2 =  $T_2$ , and so on. As shown in the diagram, the CEVT1 event is a good trigger point to read the timing data,  $T_1$ ,  $T_2$ ,  $T_3$ ,  $T_4$  are all valid here.

**Figure 20-23. Capture Sequence for Delta Mode Time-stamp and Rising Edge Detect**

### 20.6.3.1 Code snippet for CAP mode Delta Time, Rising Edge Trigger

```
// Code snippet for CAP mode Delta Time, Rising edge trigger
// Initialization Time
//=====
// ECAP module 1 config
ECap1Regs.ECCTL1.bit.CAP1POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP2POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP3POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP4POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CTRRST1 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST2 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST3 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST4 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CAPLDEN = EC_ENABLE;
ECap1Regs.ECCTL1.bit.PRESCALE = EC_DIV1;
ECap1Regs.ECCTL2.bit.CAP_APWM = EC_CAP_MODE;
ECap1Regs.ECCTL2.bit.CONT_ONESHT = EC_CONTINUOUS;
ECap1Regs.ECCTL2.bit.SYNCO_SEL = EC_SYNCO_DIS;
ECap1Regs.ECCTL2.bit.SYNCI_EN = EC_DISABLE;
ECap1Regs.ECCTL2.bit.TSCTRSTOP = EC_RUN; // Allow TSCTR to run
// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Period value.
Period4 = ECap1Regs.CAP1; // Fetch Time-Stamp captured at T1
Period1 = ECap1Regs.CAP2; // Fetch Time-Stamp captured at T2
Period2 = ECap1Regs.CAP3; // Fetch Time-Stamp captured at T3
Period3 = ECap1Regs.CAP4; // Fetch Time-Stamp captured at T4
```

## 20.6.4 Example 4 - Time Difference (Delta) Operation Rising and Falling Edge Trigger

In Figure 20-24 the eCAP operating mode is almost the same as in previous section except Capture events are qualified as either Rising or Falling edge, this now gives both Period and Duty cycle information, that is,  $\text{Period1} = T_1 + T_2$ ,  $\text{Period2} = T_3 + T_4$ , and so on;  $\text{Duty Cycle1 (on-time \%)} = T_1 / \text{Period1} \times 100\%$ , and so on;  $\text{Duty Cycle1 (off-time \%)} = T_2 / \text{Period1} \times 100\%$ , and so on.

Figure 20-24. Capture Sequence for Delta Mode Time-stamp With Rising and Falling Edge Detect

During initialization, you must write to the active registers for both period and compare. This will then automatically copy the init values into the shadow values. For subsequent compare updates, during run-time, only the shadow registers must be used.

#### 20.6.4.1 Code snippet for CAP mode Delta Time, Rising and Falling Edge Triggers

```
// Code snippet for CAP mode Delta Time, Rising and Falling edge triggers
// Initialization Time
//=====
// ECAP module 1 config
ECap1Regs.ECCTL1.bit.CAP1POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP2POL = EC_FALLING;
ECap1Regs.ECCTL1.bit.CAP3POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP4POL = EC_FALLING;
ECap1Regs.ECCTL1.bit.CTRRST1 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST2 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST3 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST4 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CAPLDEN = EC_ENABLE;
ECap1Regs.ECCTL1.bit.PRESCALE = EC_DIV1;
ECap1Regs.ECCTL2.bit.CAP_APWM = EC_CAP_MODE;
ECap1Regs.ECCTL2.bit.CONT_ONESHT = EC_CONTINUOUS;
ECap1Regs.ECCTL2.bit.SYNCO_SEL = EC_SYNCO_DIS;
ECap1Regs.ECCTL2.bit.SYNCI_EN = EC_DISABLE;
ECap1Regs.ECCTL2.bit.TSCTRSTOP = EC_RUN; // Allow TSCTR to run
// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Duty cycle values.
DutyOnTime1 = ECap1Regs.CAP2; // Fetch Time-Stamp captured at T2
DutyOffTime1 = ECap1Regs.CAP3; // Fetch Time-Stamp captured at T3
DutyOnTime2 = ECap1Regs.CAP4; // Fetch Time-Stamp captured at T4
DutyOffTime2 = ECap1Regs.CAP1; // Fetch Time-Stamp captured at T1
Period1 = DutyOnTime1 + DutyOffTime1;
Period2 = DutyOnTime2 + DutyOffTime2;
```

## 20.7 Application of the APWM Mode

In this example, the eCAP module is configured to operate as a PWM generator. Here a very simple single channel PWM waveform is generated from output pin APWMx. The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time. Note here values are in hexadecimal (h) notation.

### 20.7.1 Simple PWM Generation (Independent Channel/s)

**Figure 20-25. PWM Waveform Details of APWM Mode Operation**

#### Example 20-1. Code Snippet for APWM Mode

```
// Code snippet for APWM mode Example 1
// Initialization Time
//=====
// ECAP module 1 config
ECap1Regs.CAP1 = 0x1000; // Set period value
ECap1Regs.CTRPHS = 0x0; // make phase zero
ECap1Regs.ECCTL2.bit.CAP_APWM = EC_APWM_MODE;
ECap1Regs.ECCTL2.bit.APWMPOL = EC_ACTV_HI; // Active high
ECap1Regs.ECCTL2.bit.SYNCR_EN = EC_DISABLE; // Synch not used
ECap1Regs.ECCTL2.bit.SYNCR_SEL = EC_SYNCR_DIS; // Synch not used
ECap1Regs.ECCTL2.bit.TSCTRSTOP = EC_RUN; // Allow TSCTR to run
// Run Time (Instant 1, e.g. ISR call)
//=====
ECap1Regs.CAP2 = 0x300; // Set Duty cycle i.e. compare value
// Run Time (Instant 2, e.g. another ISR call)
//=====
ECap1Regs.CAP2 = 0x500; // Set Duty cycle i.e. compare value
```

## ***Enhanced QEP (eQEP) Module***

The enhanced quadrature encoder pulse (eQEP) module is used for direct interface with a linear or rotary incremental encoder to get position, direction, and speed information from a rotating machine for use in a high-performance motion and position-control system. This microcontroller implements 2 instances of the eQEP module.

## 21.1 Introduction

A single track of slots patterns the periphery of an incremental encoder disk, as shown in [Figure 21-1](#). These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark/light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position, and zero reference

**Figure 21-1. Optical Encoder Disk**

To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is realized with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90° out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and vice versa as shown in [Figure 21-2](#).

**Figure 21-2. QEP Encoder Output Signal for Forward/Reverse Movement**

**Legend:** N = lines per revolution

The encoder wheel typically makes one revolution for every revolution of the motor or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 KHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 21-3. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

**Figure 21-3. Index Pulse Example**

Some typical applications of shaft encoders include robotics and even computer input in the form of a mouse. Inside your mouse you can see where the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

**General Issues:** Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$v(k) \approx \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (28)$$

$$v(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (29)$$

where

$v(k)$ : Velocity at time instant  $k$

$x(k)$ : Position at time instant  $k$

$x(k-1)$ : Position at time instant  $k-1$

$T$ : Fixed unit time or inverse of velocity calculation rate

$\Delta X$ : Incremental position movement in unit time

$t(k)$ : Time instant " $k$ "

$t(k-1)$ : Time instant " $k-1$ "

$X$ : Fixed unit position

$\Delta T$ : Incremental time elapsed for unit position movement.

Equation 28 is the conventional approach to velocity estimation and it requires a time base to provide unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity  $[x(k) - x(k-1)]$  is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant  $1/T$  (where  $T$  is the constant time between unit time events and is known in advance).

Estimation based on Equation 28 has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period  $T$ . For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position the quadrature encoder gives a four-fold increase in resolution, in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example, 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, Equation 29 provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. Equation 29 can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does Equation 28. A combination of relatively large motor speeds and high sensor resolution makes the time interval  $\Delta T$  small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use Equation 29 at low speed and have the DSP software switch over to Equation 28 when the motor speed rises above some specified threshold.

## 21.2 Description

This section provides the eQEP inputs, memory map, and functional description.

### 21.2.1 EQEP Inputs

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input.

- **QEPA/XCLK and QEPB/XDIR**

These two pins can be used in quadrature-clock mode or direction-count mode.

- **Quadrature-clock Mode**

The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase whose phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and vice versa. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.

- **Direction-count Mode**

In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The QEPA pin provides the clock input and the QEPB pin provides the direction input.

- **eQEPI: Index or Zero Marker**

The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.

- **QEPS: Strobe Input**

This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG)

**Figure 21-5. Functional Block Diagram of Decoder Unit**

### 21.3.1 Position Counter Input Modes

Clock and direction input to position counter is selected using QDECCTL[QSRC] bits, based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode

#### 21.3.1.1 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

**Direction Decoding**— The direction decoding logic of the eQEP circuit determines which one of the sequences (QEPA, QEPB) is the leading sequence and accordingly updates the direction information in QEPSTS[QDF] bit. [Table 21-2](#) and [Figure 21-6](#) show the direction decoding logic in truth table and state machine form. Both edges of the QEPA and QEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. [Figure 21-7](#) shows the direction decoding and clock generation from the eQEP input signals.

**Phase Error Flag**— In normal operating conditions, quadrature inputs QEPA and QEPB will be 90 degrees out of phase. The phase error flag (PHE) is set in the QFLG register when edge transition is detected simultaneously on the QEPA and QEPB signals to optionally generate interrupts. State transitions marked by dashed lines in [Figure 21-6](#) are invalid transitions that generate a phase error.

**Count Multiplication**— The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (QEPA and QEPB) as shown in [Figure 21-7](#).

**Reverse Count**— In normal quadrature count operation, QEPA input is fed to the QA input of the quadrature decoder and the QEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the QDECCTL register. This will swap the input to the quadrature decoder thereby reversing the counting direction.

**Table 21-2. Quadrature Decoder Truth Table**

| Previous Edge | Present Edge | QDIR   | QPOSCNT                |
|---------------|--------------|--------|------------------------|
| QA↑           | QB↑          | UP     | Increment              |
|               | QB↓          | DOWN   | Decrement              |
|               | QA↓          | TOGGLE | Increment or Decrement |
| QA↓           | QB↓          | UP     | Increment              |
|               | QB↑          | DOWN   | Decrement              |
|               | QA↑          | TOGGLE | Increment or Decrement |
| QB↑           | QA↑          | DOWN   | Increment              |
|               | QA↓          | UP     | Decrement              |
|               | QB↓          | TOGGLE | Increment or Decrement |
| QB↓           | QA↓          | DOWN   | Increment              |
|               | QA↑          | UP     | Decrement              |
|               | QB↑          | TOGGLE | Increment or Decrement |

**Figure 21-6. Quadrature Decoder State Machine**

**Figure 21-7. Quadrature-clock and Direction Decoding**

### 21.3.1.2 Direction-Count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. QEPA input will provide the clock for position counter and the QEPB input will have the direction information. The position counter is incremented on every rising edge of a QEPA input when the direction input is high and decremented when the direction input is low.

### 21.3.1.3 Up-Count Mode

The counter direction signal is hard-wired for up count and the position counter is used to measure the frequency of the QEPA input. Setting of the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by 2x factor.

### 21.3.1.4 Down-Count Mode

The counter direction signal is hardwired for a down count and the position counter is used to measure the frequency of the QEPA input. Setting of the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of a QEPA input, thereby increasing the measurement resolution by 2x factor.

## 21.3.2 eQEP Input Polarity Selection

Each eQEP input can be inverted using QDECCTL[8:5] control bits. As an example, setting of QDECCTL[QIP] bit will invert the index input.

## 21.3.3 Position-Compare Sync Output

The enhanced eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position counter register (QPOSCNT) and the position-compare register (QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the QDECCTL[SOEN] bit enables the position-compare sync output and the QDECCTL[SPSEL] bit selects either an eQEP index pin or an eQEP strobe pin.

## 21.4 Position Counter and Control Unit (PCCU)

The position counter and control unit provides two configuration registers (QEPCTL and QPOSCTL) for setting up position counter operational modes, position counter initialization/latch modes and position-compare logic for sync signal generation.

### 21.4.1 Position Counter Operating Modes

Position counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse and position counter provides rotor angle with respect to index pulse position.

Position counter can be configured to operate in following four modes

- Position Counter Reset on Index Event
- Position Counter Reset on Maximum Position
- Position Counter Reset on the first Index Event
- Position Counter Reset on Unit Time Out Event (Frequency Measurement)

In all the above operating modes, position counter is reset to 0 on overflow and to QPOS MAX register value on underflow. Overflow occurs when the position counter counts up after QPOS MAX value. Underflow occurs when position counter counts down after "0". Interrupt flag is set to indicate overflow/underflow in QFLG register.

### 21.4.1.1 Position Counter Reset on Index Event (QEPCTL[PCRM] = 00)

If the index event occurs during the forward movement, then position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of QEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of QEPB for the forward rotation and on the rising edge of QEPB for the reverse rotation as shown in Figure 21-8.

The position-counter value is latched to the QPOSILAT register and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (QEPSTS[PCEF]) and error interrupt flag (QFLG[PCE]) are set if the latched value is not equal to 0 or QPOSMAX. The position-counter error flag (QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (QFLG[PCE]) will be set on error that can be cleared only through software.

The index event latch configuration QEPCTL[IEL] bits are ignored in this mode and position counter error flag/interrupt flag are generated only in index event reset mode.

**Figure 21-8. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOSMAX = 3999 or 0xF9F)**

### 21.4.1.2 Position Counter Reset on Maximum Position (QEPCTL[PCRM] = 01)

If the position counter is equal to QPOS MAX, then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOS MAX on the next QEP clock for reverse movement and position counter underflow flag is set. Figure 21-9 shows the position counter reset operation in this mode.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers; it also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for the software index marker (QEPCTL[IEL]=11).

**Figure 21-9. Position Counter Underflow/Overflow (QPOS MAX = 4)**

### 21.4.1.3 Position Counter Reset on the First Index Event (QEPCTL[PCRM] = 10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position counter value is not reset on an index event; rather, it is reset based on maximum position as described in [Section 21.4.1.2](#).

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for software index marker (QEPCTL[IEL]=11).

### 21.4.1.4 Position Counter Reset on Unit Time out Event (QEPCTL[PCRM] = 11)

In this mode, the QPOSCNT value is latched to the QPOSILAT register and then the QPOSCNT is reset (to 0 or QPOSMAX, depending on the direction mode selected by QDECCTL[QSRC] bits on a unit time event). This is useful for frequency measurement.

## 21.4.2 Position Counter Latch

The eQEP index and strobe input can be configured to latch the position counter (QPOSCNT) into QPOSILAT and QPOSSLAT, respectively, on occurrence of a definite event on these pins.

### 21.4.2.1 Index Event Latch

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (QEPCTL[PCRM] = 01 and QEPCTL[PCRM] = 10 modes).

In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (QEPCTL[IEL]=01)
- Latch on Falling edge (QEPCTL[IEL]=10)
- Latch on Index Event Marker (QEPCTL[IEL]=11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (QFLG[IEL]) is set when the position counter is latched to the QPOSILAT register. The index event latch configuration bits (QEPCTZ[IEL]) are ignored when QEPCTL[PCRM] = 00.

**Latch on Rising Edge (QEPCTL[IEL]=01)**— The position counter value (QPOSCNT) is latched to the QPOSILAT register on every rising edge of an index input.

**Latch on Falling Edge (QEPCTL[IEL] = 10)**— The position counter value (QPOSCNT) is latched to the QPOSILAT register on every falling edge of index input.

**Latch on Index Event Marker/Software Index Marker (QEPCTL[IEL] = 11)**— The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for latching the position counter (QEPCTL[IEL]=11).

[Figure 21-10](#) shows the position counter latch using an index event marker.

**Figure 21-10. Software Index Marker for 1000-line Encoder (QEPCTL[IEL] = 1)**

#### 21.4.2.2 Strobe Event Latch

The position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input by clearing the QEPCTL[SEL] bit.

If the QEPCTL[SEL] bit is set, then the position counter value is latched to the QPOSSLAT register on the rising edge of the strobe input for forward direction and on the falling edge of the strobe input for reverse direction as shown in [Figure 21-11](#).

The strobe event latch interrupt flag (QFLG[SEL]) is set when the position counter is latched to the QPOSSLAT register.

**Figure 21-11. Strobe Event Latch (QEPCTL[SEL] = 1)**

### 21.4.3 Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization

**Index Event Initialization (IEI)**— The QEPI index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input. If the QEPCTL[IEI] bits are 10, then the position counter (QPOSCNT) is initialized with a value in the QPOSINIT register on the rising edge of index input. Conversely, if the QEPCTL[IEI] bits are 11, initialization will be on the falling edge of the index input.

**Strobe Event Initialization (SEI)**— If the QEPCTL[SEI] bits are 10, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input.

If QEPCTL[SEL] bits are 11, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

**Software Initialization (SWI)**— The position counter can be initialized in software by writing a 1 to the QEPCTL[SWI] bit. This bit is not automatically cleared. While the bit is still set, if a 1 is written to it again, the position counter will be re-initialized.

### 21.4.4 eQEP Position-compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. Figure 21-12 shows a diagram. The position-compare (QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the QPOSCTL[PSSHDW] bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

**Figure 21-12. eQEP Position-compare Unit**

In shadow mode, you can configure the position-compare unit (QPOSCTL[PCLOAD]) to load the shadow register value into the active register on the following events and to generate the position-compare ready (QFLG[PCR]) interrupt after loading.

- Load on compare match
- Load on position-counter zero event

The position-compare match (QFLG[PCM]) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare match to trigger an external device.

For example, if QPOSCMP = 2, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see [Figure 21-13](#)).

[Section 21.9.14](#) shows the layout of the eQEP Position-Compare Control Register (QPOSCTL) and describes the QPOSCTL bit fields.

**Figure 21-13. eQEP Position-compare Event Generation Points**

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in [Figure 21-14](#).

**Figure 21-14. eQEP Position-compare Sync Output Pulse Stretcher**

## 21.5 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in [Figure 21-15](#). This feature is typically used for low speed measurement using the following equation:

$$v(k) = \frac{X}{t(k) - t(k - 1)} = \frac{X}{\Delta T} \quad (30)$$

where,

- X - Unit position is defined by integer multiple of quadrature edges (see [Figure 21-16](#))
- $\Delta T$  - Elapsed time between unit position events
- $v(k)$  - Velocity at time instant "k"

The eQEP capture timer (QCTMR) runs from prescaled VCLK4 and the prescaler is programmed by the QCAPCTL[CCPS] bits. The capture timer (QCTMR) value is latched into the capture period register (QCPRD) on every unit position event and then the capture timer is reset, a flag is set in QEPSTS:UPEVNT to indicate that new value is latched into the QCPRD register. Software can check this status flag before reading the period register for low speed measurement and clear the flag by writing 1.

Time measurement ( $\Delta T$ ) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

The capture unit sets the eQEP overflow error flag (QEPSTS[COEF]) in the event of capture timer overflow between unit position events. If a direction change occurs between the unit position events, then an error flag is set in the status register (QEPSTS[CDEF]).

Capture Timer (QCTMR) and Capture period register (QCPRD) can be configured to latch on following events.

- CPU read of QPOSCNT register
- Unit time-out event

If the QEPCTL[QCLM] bit is cleared, then the capture timer and capture period values are latched into the QCTMRLAT and QCPRDLAT registers, respectively, when the CPU reads the position counter (QPOSCNT).

If the QEPCTL[QCLM] bit is set, then the position counter, capture timer, and capture period values are latched into the QPOSLAT, QCTMRLAT and QCPRDLAT registers, respectively, on unit time out.

[Figure 21-17](#) shows the capture unit operation along with the position counter.

Figure 21-15. eQEP Edge Capture Unit

**NOTE:** The QCAPCTL[UPPS] prescaler should not be modified dynamically (such as switching the unit event prescaler from QCLK/4 to QCLK/8). Doing so may result in undefined behavior. The QCAPCTL[CCPS] prescaler can be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLK/4 to SYSCLK/8) only after the capture unit is disabled.

Figure 21-16. Unit Position Event for Low Speed Measurement (QCAPCTL[UPPS] = 0010)

N = Number of quadrature periods selected using QCAPCTL[UPPS] bits

**Figure 21-17. eQEP Edge Capture Unit - Timing Details**

Velocity Calculation Equations:

$$v(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (31)$$

where

$v(k)$ : Velocity at time instant  $k$

$x(k)$ : Position at time instant  $k$

$x(k-1)$ : Position at time instant  $k-1$

$T$ : Fixed unit time or inverse of velocity calculation rate

$\Delta X$ : Incremental position movement in unit time

$X$ : Fixed unit position

$\Delta T$ : Incremental time elapsed for unit position movement

$t(k)$ : Time instant " $k$ "

$t(k-1)$ : Time instant " $k-1$ "

Unit time ( $T$ ) and unit period( $X$ ) are configured using the QUPRD and QCAPCTL[UPPS] registers. Incremental position output and incremental time output is available in the QPOSLAT and QCPRDLAT registers.

| Parameter  | Relevant Register to Configure or Read the Information                  |
|------------|-------------------------------------------------------------------------|
| T          | Unit Period Register (QUPRD)                                            |
| $\Delta X$ | Incremental Position = QPOSAT(k) - QPOSAT(K-1)                          |
| X          | Fixed unit position defined by sensor resolution and ZCAPCTL[Upps] bits |
| $\Delta T$ | Capture Period Latch (QCPRDLAT)                                         |

## 21.6 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer that monitors the quadrature-clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from VCLK4/64 and the quadrature clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match ( $QWDPRD = QWDTMR$ ), then the watchdog timer will time out and the watchdog interrupt flag will be set (QFLG[WTO]). The time-out value is programmable through the watchdog period register (QWDPRD).

**Figure 21-18. eQEP Watchdog Timer**

## 21.7 Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by VCLK4 to generate periodic interrupts for velocity calculations. The unit time out interrupt is set (QFLG[UTO]) when the unit timer (QUTMR) matches the unit period register (QUPRD).

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in [Section 21.5](#).

**Figure 21-19. eQEP Unit Time Base**

**Table 21-3. EQEP REGISTERS (continued)**

| Offset | Acronym  | Register Name                      | Section                         |
|--------|----------|------------------------------------|---------------------------------|
| 34h    | QFRC     | eQEP Interrupt Force Register      | <a href="#">Section 21.9.18</a> |
| 36h    | QCLR     | eQEP Interrupt Clear Register      | <a href="#">Section 21.9.19</a> |
| 38h    | QCTMR    | eQEP Capture Timer Register        | <a href="#">Section 21.9.20</a> |
| 3Ah    | QEPSTS   | eQEP Status Register               | <a href="#">Section 21.9.21</a> |
| 3Ch    | QCTMRLAT | eQEP Capture Timer Latch Register  | <a href="#">Section 21.9.22</a> |
| 3Eh    | QCPRD    | eQEP Capture Period Register       | <a href="#">Section 21.9.23</a> |
| 42h    | QCPRDLAT | eQEP Capture Period Latch Register | <a href="#">Section 21.9.24</a> |

### 21.9.1 QPOSCNT Register (offset = 0h) [reset = 0h]

QPOSCNT is shown in [Figure 21-21](#) and described in [Table 21-4](#).

**Figure 21-21. QPOSCNT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 21-4. QPOSCNT Register Field Descriptions**

| Bit  | Field   | Type | Reset | Description                                                                                                                                                                                                              |
|------|---------|------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | QPOSCNT | R/W  | 0h    | This 32-bit position counter register counts up/down on every eQEP pulse based on direction input. This counter acts as a position integrator whose count value is proportional to position from a give reference point. |

### 21.9.2 QPOSINIT Register (offset = 4h) [reset = 0h]

QPOSINIT is shown in [Figure 21-22](#) and described in [Table 21-5](#).

**Figure 21-22. QPOSINIT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 21-5. QPOSINIT Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description                                                                                                                                                                                  |
|------|----------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | QPOSINIT | R/W  | 0h    | This register contains the position value that is used to initialize the position counter based on external strobe or index event. The position counter can be initialized through software. |

### 21.9.3 QPOSMAX Register (offset = 8h) [reset = 0h]

QPOSMAX is shown in [Figure 21-23](#) and described in [Table 21-6](#).

**Figure 21-23. QPOSMAX Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 21-6. QPOSMAX Register Field Descriptions**

| Bit  | Field   | Type | Reset | Description                                                |
|------|---------|------|-------|------------------------------------------------------------|
| 31-0 | QPOSMAX | R/W  | 0h    | This register contains the maximum position counter value. |

### 21.9.4 QPOSCMP Register (offset = Ch) [reset = 0h]

QPOSCMP is shown in [Figure 21-24](#) and described in [Table 21-7](#).

**Figure 21-24. QPOSCMP Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 21-7. QPOSCMP Register Field Descriptions**

| Bit  | Field   | Type | Reset | Description                                                                                                                                            |
|------|---------|------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | QPOSCMP | R/W  | 0h    | The position-compare value in this register is compared with the position counter (QPOSCNT) to generate sync output and/or interrupt on compare match. |

### 21.9.5 QPOSILAT Register (offset = 10h) [reset = 0h]

QPOSILAT is shown in [Figure 21-25](#) and described in [Table 21-8](#).

**Figure 21-25. QPOSILAT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 21-8. QPOSILAT Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description                                                                                                    |
|------|----------|------|-------|----------------------------------------------------------------------------------------------------------------|
| 31-0 | QPOSILAT | R    | 0h    | The position-counter value is latched into this register on an index event as defined by the QEPCTL[IEL] bits. |

### 21.9.6 QPOSSLAT Register (offset = 14h) [reset = 0h]

QPOSSLAT is shown in [Figure 21-26](#) and described in [Table 21-9](#).

**Figure 21-26. QPOSSLAT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 21-9. QPOSSLAT Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description                                                                                                  |
|------|----------|------|-------|--------------------------------------------------------------------------------------------------------------|
| 31-0 | QPOSSLAT | R    | 0h    | The position-counter value is latched into this register on strobe event as defined by the QEPCTL[SEL] bits. |

### 21.9.7 QPOSLAT Register (offset = 18h) [reset = 0h]

QPOSLAT is shown in [Figure 21-27](#) and described in [Table 21-10](#).

**Figure 21-27. QPOSLAT Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 21-10. QPOSLAT Register Field Descriptions**

| Bit  | Field   | Type | Reset | Description                                                                      |
|------|---------|------|-------|----------------------------------------------------------------------------------|
| 31-0 | QPOSLAT | R    | 0h    | The position-counter value is latched into this register on unit time out event. |

### 21.9.8 QUTMR Register (offset = 1Ch) [reset = 0h]

QUTMR is shown in [Figure 21-28](#) and described in [Table 21-11](#).

**Figure 21-28. QUTMR Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 21-11. QUTMR Register Field Descriptions**

| Bit  | Field | Type | Reset | Description                                                                                                                                              |
|------|-------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | QUTMR | R/W  | 0h    | This register acts as time base for unit time event generation. When this timer value matches with unit time period value, unit time event is generated. |

### 21.9.9 QUPRD Register (offset = 20h) [reset = 0h]

QUPRD is shown in [Figure 21-29](#) and described in [Table 21-12](#).

**Figure 21-29. QUPRD Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 21-12. QUPRD Register Field Descriptions**

| Bit  | Field | Type | Reset | Description                                                                                                                                                                                    |
|------|-------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | QUPRD | R/W  | 0h    | This register contains the period count for unit timer to generate periodic unit time events to latch the eQEP position information at periodic interval and optionally to generate interrupt. |

### 21.9.10 QWDPRD Register (offset = 24h) [reset = 0h]

QWDPRD is shown in [Figure 21-30](#) and described in [Table 21-13](#).

**Figure 21-30. QWDPRD Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 21-13. QWDPRD Register Field Descriptions**

| Bit  | Field  | Type | Reset | Description                                                                                                                                                                                   |
|------|--------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | QWDPRD | R/W  | 0h    | This register contains the time-out count for the eQEP peripheral watchdog timer. When the watchdog timer value matches the watchdog period value, a watchdog timeout interrupt is generated. |

### 21.9.11 QWDTMR Register (offset = 26h) [reset = 0h]

QWDTMR is shown in [Figure 21-31](#) and described in [Table 21-14](#).

**Figure 21-31. QWDTMR Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 21-14. QWDTMR Register Field Descriptions**

| Bit  | Field  | Type | Reset | Description                                                                                                                                                                                                                                                    |
|------|--------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | QWDTMR | R/W  | 0h    | This register acts as time base for watchdog to detect motor stalls. When this timer value matches with watchdog period value, watchdog timeout interrupt is generated. This register is reset upon edge transition in quadrature-clock indicating the motion. |

## 21.9.12 QEPCCTL Register (offset = 28h) [reset = 0h]

QEPCCTL is shown in [Figure 21-32](#) and described in [Table 21-15](#).

## ***Analog To Digital Converter (ADC) Module***

This chapter describes the analog to digital converter (ADC) interface module.

---

**NOTE:** This chapter describes a superset implementation of the ADC module that includes features and functionality that require DMA. Since not all devices have DMA capability, consult your device-specific datasheet to determine applicability of these features and functions to your device being used.

## 22.1 Overview

This microcontrollers implements up to two instances of the ADC module. The main features of the ADC module are:

- Selectable 10-bit or 12-bit resolution
- Successive-approximation-register architecture
- Three conversion groups – Group1, Group2 and Event Group
- All three conversion groups can be configured to be hardware-triggered; group1 and group2 can also be triggered by software
- Conversion results are stored in a 64-word memory (SRAM)
  - These 64 words are divided between the three conversion groups and are configurable by software
  - Accesses to the conversion result RAM are protected by parity
- Flexible options for generating DMA requests for transferring conversion results
- Selectable channel conversion order
  - Sequential conversions in ascending order of channel number, OR
  - User-defined channel conversion order with the Enhanced Channel Selection Mode
- Single or continuous conversion modes
- Embedded self-test logic for input channel failure detection (open / short to power / short to ground)
- Embedded calibration logic for offset error correction
- Enhanced Power-down mode
- External event pin (ADEVT) to trigger conversions
  - ADEVT is also programmable as general-purpose I/O
- Eight hardware events to trigger conversions

The two instances of the 12-bit ADC modules on the microcontroller share 16 analog input channels. The connections are shown in [Figure 22-1](#).

**Figure 22-1. Channel Assignments of Two ADC Cores**

- ADC1 supports 24 channels.
- ADC2 supports 16 channels, all of which are shared with ADC1.
- The reference voltages as well as operating supply and ground are shared between the two ADC cores.

## 22.2 Introduction

This section presents a brief functional description of the analog-to-digital converter (ADC) module. [Figure 22-2](#) illustrates the components of the ADC module.

**Figure 22-2. ADC Block Diagram**

### 22.2.1 Input Multiplexor

The input multiplexor (MUX) connects the selected input channel to the AIN input of the ADC core. The ADC1 module supports up to 24 inputs as shown in [Figure 22-2](#). The ADC2 module supports up to 16 inputs. The sequencer selects the channel to be converted. Enabling the enhanced channel selection mode also allows one or more of the analog input channels to be connected to the output of an external analog switch or multiplexor.

### 22.2.2 Self-Test and Calibration Cell

The ADC includes specific hardware that allows a software algorithm to detect open/short on an ADC analog input. It also allows the application program to calibrate the ADC. Also see [Section 22.8.1](#) and [Section 22.8.2](#).

### 22.2.3 Analog-to-Digital Converter Core

The ADC core is a combination voltage scaling, charge redistribution Successive Approximation Register (SAR) based analog-to-digital converter. The core can be configured for operation in 10-bit resolution (default) or 12-bit resolution. This is controlled by the sequencer logic. This selection applies to all conversions performed by the ADC module. It is not possible to convert some channels with a 12-bit resolution and some with a 10-bit resolution.

A single conversion from an analog input to a digital conversion result occurs in two distinct periods:

- Sampling Period:
  - The sequencer generates a START signal to the ADC core to signal the start of the sampling period.
  - The analog input signal is sampled directly on to the switched capacitor array during this period, providing an inherent sample-and-hold function.
  - The sampling period ends one full ADCLK after the falling edge of the START signal.
  - The sequencer can control the sampling period duration by configuring the conversion group's sample time control register (ADEVSAMP, ADG1SAMP, ADG2SAMP). This register controls the time for which the START signal stays high.
- Conversion Period:
  - The conversion period starts one full ADCLK after the falling edge of START.
  - One bit of the conversion result is output on each rising edge of ADCLK in the conversion period, starting with the most-significant bit first.
  - The conversion period is 12 ADCLK cycles in case of a 12-bit ADC, and is 10 ADCLK cycles in case of a 10-bit ADC.
  - The ADC core generates an End-Of-Conversion (EOC) signal to the sequencer at the end of the conversion period. At this time the complete 12-, or 10-bit conversion result is available.
  - The sequencer captures the ADC core conversion result output as soon as EOC is driven High.

The analog conversion range is determined by the reference voltages:  $AD_{REFHI}$  and  $AD_{REFLO}$ .  $AD_{REFHI}$  is the top reference voltage and is the maximum analog voltage that can be converted. An analog input voltage equal to  $AD_{REFHI}$  results in an output code of 0x3FF for 10-bit resolution and 0xFFF for 12-bit resolution.  $AD_{REFLO}$  is the bottom reference voltage and is the minimum analog voltage that can be converted. Applying an input equal to  $AD_{REFLO}$  results in an output code of 0x000. Both  $AD_{REFHI}$  and  $AD_{REFLO}$  must be chosen not to exceed the analog power supplies:  $V_{CCAD}$  and  $V_{SSAD}$  respectively. Input voltages between  $AD_{REFHI}$  and  $AD_{REFLO}$  produce a conversion result given by ([Equation 32](#)) for 10-bit resolution and ([Equation 33](#)) for 12-bit resolution.

$$DigitalResult = \frac{1024 \times (InputVoltage - AD_{REFLO})}{AD_{REFHI} - AD_{REFLO}} - 0.5 \quad (32)$$

$$DigitalResult = \frac{4096 \times (InputVoltage - AD_{REFLO})}{(AD_{REFHI} - AD_{REFLO})} - 0.5 \quad (33)$$

### 22.2.4 Sequencer

The sequencer coordinates the operations of the ADC, including the input multiplexor, the ADC core, and the result memory. In addition, the logic of the sequencer sets the status register flags when the conversion is ongoing, stopped, or finished.

All the features of the sequencer are discussed in detail in the following sections of this document.

### 22.2.5 Conversion Groups

Several applications require groups of channels to be converted using a single trigger source for example. There could also be some groups of channels identified which require a specific setting of the acquisition time. The ADC module supports three conversion groups for this purpose – Group1, Group2 and the Event Group.

Any of the available analog input channels can be assigned to any of the conversion groups. This also allows a particular channel to be repeatedly sampled by selecting it in multiple groups. There is an inherent priority scheme used when multiple conversion groups are triggered at once. The Event Group is the highest-priority, followed by the Group1 and then the Group2.

The Event Group is always hardware event-triggered. Group1 and Group2 are software-triggered by default and can be configured to be hardware-, or event-triggered as well. The triggering of conversions in each group is discussed in [Section 22.3.6](#).

Each conversion group has a separate set of control registers to:

- Select the input channels to be converted
- Configure the mode of conversion: single conversion sequence or continuous conversions
- Configure the input channel sampling time
- Configure the interrupt and/or DMA request generation conditions

## 22.3 Basic Features and Usage of the ADC

This section describes the usage of the basic features of the ADC module.

### 22.3.1 How to Select Between 12-bit and 10-bit Resolutions

The 10/12-BIT field of the ADC Operating Mode Control Register (ADOPMODECR) configures the ADC to be in 10-bit or 12-bit resolution mode.

- If 10/12-BIT = 0, the module is in 10-bit resolution mode. This is the default mode of operation.
- If 10/12-BIT = 1, the module is in 12-bit resolution mode.

### 22.3.2 How to Set Up the ADCLK Speed

The ADC sequencer generates the clock for the ADC core, ADCLK. The ADC core uses the ADCLK signal for its timing. The ADCLK is generated by dividing down the input clock to the ADC module, which is the VBUSP interface clock, VCLK. A 5-bit field (PS) in the ADC Clock Control Register (ADCLOCKCR) is used to divide down the VCLK by 1 up to 32. The ADCLK valid frequency range is specified in the device datasheet.

$$f_{\text{ADCLK}} = f_{\text{VCLK}} / (\text{PS} + 1)$$

The maximum frequency for ADCLK is specified in the device datasheet.

### 22.3.3 How to Set Up the Input Channel Acquisition Time

The signal acquisition time for each group is separately configurable using the ADG1SAMP[11:0], ADG2SAMP[11:0], and ADEVSAMP[11:0] registers.

The acquisition time is specified in terms of ADCLK cycles and ranges from a minimum of 2 ADCLK cycles to a maximum of 4098 ADCLK cycles.

For example, Group1 acquisition time,  $t_{\text{ACQG1}} = \text{G1SAMP}[11:0] + 2$ , in ADCLK cycles.

The minimum acquisition time is specified in the device datasheet. This time also depends on the impedance of the circuit connected to the analog input channel being converted.

### 22.3.4 How to Select an Input Channel for Conversion

The ADC module needs to be enabled first before selecting an input channel for conversion. The ADC module can be enabled by setting the ADC EN bit in the ADC Operating Mode Control Register (ADOPMODECR). Multiple input channels can be selected for conversion in each group. Only one input channel is converted at a time. The channels to be converted are configured in one or more of the three conversion groups' channel selection registers. Channels to be converted in Group1 are configured in the Group1 Channel-Select Register (ADG1SEL), those to be converted in Group2 are configured in the Group2 Channel-Select Register (ADG2SEL), and those to be converted in the Event Group are configured in the Event Group Channel-Select Register (ADEVSEL).

The description in this section only refers to the case when the enhanced channel selection mode is not enabled. Input channel selection in the enhanced channel selection mode is defined in [Section 22.4](#).

### 22.3.5 How to Select Between Single Conversion Sequence or Continuous Conversions

Each group has its own mode control register. The CONV MODE field of these control registers allow the application to select between a single conversion sequence or continuous conversion mode.

---

**NOTE:** Selecting continuous conversion mode for all three groups

All three conversion groups cannot be configured to be in a continuous conversion mode. If the application configures the group mode control registers to enable continuous conversion mode for all three groups, then the Group2 will be automatically be configured to be in a single conversion sequence mode.

---

With conversions ongoing in continuous conversion mode, if the CONV MODE field of a group is cleared, then that group switches to the single conversion sequence mode. Conversions for this group will stop once all channels selected for that group have been converted.

### 22.3.6 How to Start a Conversion

The conversion groups Group1 and Group2 are software-triggered by default. A conversion in these groups can be started just by writing the desired channels to the respective Channel-Select Registers. For example, in order to convert channels 0, 1, 2, and 3 in Group1 and channels 8, 9, 10, and 11 in Group2, the application just has to write 0x0000000F to ADG1SEL and 0x00000F00 to ADG2SEL. The ADC module will start by servicing the group that was triggered first, Group1 in this example.

The conversions for all groups are performed in ascending order of the channel number. For the Group1 the conversions will be performed in the order: channel 0 first, followed by channel 1, then channel 2, and then channel 3. The Group2 conversions will be performed in the order: channels 8, 9, 10, and 11.

The Event Group is only hardware-triggered. There are up to eight hardware event trigger sources defined for the ADC module. Check the device datasheet for a complete listing of these eight hardware trigger options.

The trigger source to be used needs to be configured in the ADEVSR register. Similar registers also exist for the Group1 and Group2 as these can also be configured to be event-triggered.

The polarity of the event trigger is also configurable, with a falling edge being the default.

An Event Group conversion starts when at least one channel is selected for conversion in this group, and when the defined event trigger occurs.

If any conversion group is configured to be in a continuous conversion mode, then it needs to only be triggered once. All the channels selected for conversion in that group will be converted repeatedly.

### 22.3.7 How to Know When the Group Conversion is Completed

Each conversion group has a status flag to indicate when its conversion has ended. See ADEVSR, ADG1SR and ADG2SR. This bit is set when a conversion sequence for a group ends. This bit does is always set if a group is configured for continuous conversions.

### 22.3.8 How Results are Stored in the Results' Memory

The ADC stores the conversion results in three separate memory regions in the ADC Results' RAM, one region for each group. Each memory region is a stack of buffers, with each buffer capable of holding one conversion result. The number of buffers allocated for each group is programmed by configuring the ADC module registers ADBNDCR and ADBNDEND.

ADBNDCR contains two 9-bit pointers BNDA and BNDB. BNDA, BNDB and BNDEND are used to partition the total memory available into three memory regions as shown in [Figure 22-3](#). Both BNDA and BNDB are pointers referenced from the start of the results' memory. BNDA specifies the number of buffers allocated for the Event Group conversion results in units of two buffers; BNDB specifies the number of buffers allocated for the Event Group plus Group1 in units of two buffers. Refer to [Section 22.11.23](#) for more details on configuring the ADC results' memory.

ADBNDEND contains a 3-bit field called BNDEND that configures the total memory available. The ADC module can support up to 1024 buffers. The device supports a maximum of 64 buffers for both the ADC modules.

**Figure 22-3. FIFO Implementation**

- Number of buffers for Event Group =  $2 \times \text{BNDA}$
- Number of buffers for Group1 =  $2 \times (\text{BNDB} - \text{BNDA})$
- Number of buffers for Group2 = Total number of buffers –  $2 \times \text{BNDB}$

### 22.3.9 How to Read the Results from the Results' Memory

The CPU can read the conversion results in one of two ways:

- By using the conversion results memory as a FIFO queue, or
- By accessing the conversion results memory directly

#### 22.3.9.1 Reading Conversion Results from a FIFO

The conversion results for each group can be accessed via a range of addresses provided to facilitate the use of the ARM Cortex-R4 CPU's Load-Multiple (LDM) instruction. A single read performed using the LDR instruction can also be used to read out a single conversion result. The results are read out from the group's memory region as a FIFO queue by reading from any location inside this address range. The conversion result that got stored first gets read first. A result that is read from the memory in this method is removed from the memory. For example, a read from any address in the range ADEVBUFFER (offset 90h to AFh) pulls out one conversion result from the Event Group memory.

**Figure 22-4. Format of Conversion Result Read from FIFO, 12-bit ADC**

|                            | G2 EMPTY |    | G2 CHID |    |    |    |    | G2 DR |    |    |    |    |    |    |    |    |

#### Option to read channel id along with conversion result:

The application has an option to read the channel id along with the conversion result. This is controlled by the CHID field of the group's mode control register. If the option to read the channel id is not selected, the channel id field of the conversion result reads as zeros.

#### Protection against reading from empty FIFO:

There is also a hardware mechanism to protect the application from reading past the number of new conversion results held in the FIFO. Once all available conversion results have been read out of the FIFO by the application, a subsequent read from the FIFO causes the mechanism to indicate that the FIFO is empty by setting the EMPTY field.

#### Debug / Emulation Support:

For debug purposes, each conversion group also provides an address that the application can read from for extracting the group's conversion results. However, no status flags for a conversion group are affected by reading from these emulation buffer addresses. For example, reading from ADEVEMUBUFFER (offset 0xF0) returns the next result in the Event Group buffer but does not actually remove that result from the buffer or change the amount of data held in the buffer.

### 22.3.9.2 Reading Conversion Results Directly from the Conversion Results' Memory

The conversion result memory is part of the device's memory map. The base address for the ADC1 result memory is 0xFF3E0000, while that for the ADC2 result memory is 0xFF3A0000.

**Figure 22-6. ADC Memory Mapping**

The application can identify the address ranges for each of the three memory regions for the three conversion groups after performing the segmentation as described in [Section 22.3.8](#). It is up to the application to read the desired results from the three conversion groups. The formats of the conversion results when reading from RAM directly are shown in [Figure 22-7](#) and [Figure 22-8](#).

**Figure 22-7. Format of Conversion Result Directly Read from ADC RAM, 12-bit ADC**

|-----------------|----------|------------------|----------|----------|----------|----------|--------------------------|---------|---------|---------|---------|---------|---------|---------|---------|---------|
|                 | 31<br>15 | 30<br>14         | 29<br>13 | 28<br>12 | 27<br>11 | 26<br>10 | 25<br>9                  | 24<br>8 | 23<br>7 | 22<br>6 | 21<br>5 | 20<br>4 | 19<br>3 | 18<br>2 | 17<br>1 | 16<br>0 |
| ADC RAM address | Reserved |                  |          |          |          |          |                          |         |         |         |         |         |         |         |         |         |
|                 | Rsvd     | channel id [4–0] |          |          |          |          | 10-bit conversion result |         |         |         |         |         |         |         |         |         |

Note that there is no EMPTY field to protect the application from reading data that has been previously read.

Each group does have a separate register which holds the address in the group's result memory where the ADC will write the next conversion result. These are the ADEV RAMWRADDR, ADG1RAMWRADDR and ADG2RAMWRADDR registers. The application can use this information to calculate how many valid conversion results are available to be read.

#### **Benefit of reading conversion results directly from ADC RAM:**

The application does not have to read out conversion results sequentially as in the case of reading from a FIFO. As a result, the application can selectively read the conversion results for any particular input channel of interest without having to read other channels' conversion results.

### 22.3.9.3 Example

Suppose that channels 0, 1, and 2 are selected for conversion in the Event Group, channels 4, 7, and 8 are selected for conversion in group 1, and channels 3, 5, and 6 are selected for conversion in group 2. The conversion results will get stored in the three memory regions as shown in Figure 22-9.

Suppose that the CPU wants to read out the results for the Event Group from a FIFO queue. The CPU needs to read from any address in the range ADEVBUFFER (offset 0x90 to 0xAF) multiple times, or do a "load multiple" from this range of addresses. This will cause the ADC to return the results for channel 0, then channel 1, then channel 2, then channel 0, and so on for each read access to this address range.

Now suppose that the application wants to read out the results for the group 1 from the RAM directly. The conversion results for the group 1 are accessible starting from address ADC RAM Base Address + BNDA. Also, it is known that the first result at this address is for the input channel 4, the next one is for input channel 7, and so on. So the application can selectively read the conversion results for only one channel if so desired.

**Figure 22-9. Conversion Results Storage**

### 22.3.10 How to Stop a Conversion

A group's conversion can be stopped by clearing the group's channel select register.

### 22.3.11 Example Sequence for Basic Configuration of ADC Module

The following sequence is necessary to configure the ADC to convert channels 0, 2, 4, and 8 in single-conversion mode using Group1:

1. Write 0 to the Reset Control Register (ADRSTCR) to release the module from the reset state
2. Write 1 to the ADC EN bit of the Operating Mode Control Register (ADOPMODECR) to enable the ADC state machine
3. Configure the ADCLK frequency by programming the desired divider into the Clock Control Register (ADCLOCKCR)
4. Configure the acquisition time for the group that is to be used. For example, configure the Group1 Sampling Time Control Register (ADG1SAMP) to set the acquisition time for Group1.
5. Select the channels that need to be converted in Group1 by writing to the Group1 Channel Select Register (ADG1SEL). In this example, a value of 0x115 needs to be written to ADG1SEL in order to select channels 0, 2, 4, and 8 for conversion in Group1.
  - The ADC sequencer will start the Group1 conversions as soon as the write to the ADG1SEL register is completed.
6. Wait for the GP1 END bit to be set in the Group1 Conversion Status Register (ADG1SR). This bit gets set when all the channels selected for conversion in Group1 are converted and the results are stored in the Group1 memory.
7. Read the conversion results by reading from the Group1 FIFO access location (ADG1BUFFER) or by reading directly from the Group1 results' memory.

Figure 22-10 shows the operating mode control registers and the status registers for each of the three conversion groups. The register addresses shown are offsets from the base address. The ADC1 register frame base address is FFF7 C000h and the ADC2 register frame base address is FFF7 C200h.

## 22.4.2 Analog Input Channel Selection Mode Options

The ADC modules on this device support two different modes for selecting the analog input channel to be converted. These are the sequential channel selection mode (default), and the enhanced channel selection mode. These two modes are now described:

### 22.4.2.1 Sequential Channel Selection Mode

This is the default mode and allows the ADC module to be used in a backwards compatible mode to the ADC module on other Hercules™ ARM® Safety MCUs from Texas Instruments. As discussed in [Section 22.3.4](#), an analog input channel can be selected for conversion in one or more conversion groups by setting the bit corresponding to that channel number in the group's channel select register.

### 22.4.2.2 Enhanced Channel Selection Mode

There are some important concepts related to the enhanced channel selection mode. These are defined first:

- **Look-Up Table**  
This is a 32-word deep memory-mapped region used to define the analog input channel number to be converted. The LUTs for the three groups are stacked together so that the entire LUT occupies 96 words. Each word is aligned on a 32-bit boundary. The LUTs for ADC1 start at 0xFF3E2000 and the LUTs for ADC2 start at 0xFF3A2000.
- **Conversion Group Sub-Sequence**  
A group sub-sequence is defined as the conversion for a set of channels that is converted on each conversion trigger. The number of channels selected for conversion in a group sub-sequence is defined by the number of bits that are set in the group's channel select register. For example, setting bits 0, 1, 29 and 31 in ADG1SEL means that each Group1 conversion sub-sequence consists of 4 conversions.
- **LUT Index**  
A "CURRENT\_COUNT" register for each group is maintained as an index into that group's LUT. This register increments each time a channel conversion is completed. Therefore, as its name suggests, a read from this register returns the number of conversions completed since the last write to the group's channel select register. The CURRENT\_COUNT register resets to all zeros under either of the following conditions:
  1. The ADC peripheral is reset via a global peripheral reset, OR
  2. The ADC peripheral is reset via the ADC Reset Control Register, [Section 22.11.1](#), OR
  3. The CURRENT\_COUNT becomes equal to the MAX\_COUNT defined for that conversion group, OR
  4. The application writes zeros to the CURRENT\_COUNT register, OR
  5. The conversion group's result RAM is reset
- **Maximum Number of Conversions**  
A "MAX\_COUNT" register for each conversion group stores the maximum number of conversions to be performed before the index into a group's LUT is reset to zero. This register can be programmed to a value between 0 and 31. It is recommended to program the MAX\_COUNT register with a value that is one less than a multiple of the number of channels in that group's conversion sub-sequence (number of bits that are set in the group's channel select register).

### 22.4.2.2.1 Look-Up Table Details

As described earlier, each conversion group has a look-up table (LUT) which is used when the enhanced channel selection mode is enabled. This look-up table starts at an offset of 8kB from the base of the ADC results RAM. The LUT holds 32 entries for each of the three conversion groups. The first 32 entries are for the event group, the next 32 entries are for Group1 and the last 32 entries are for Group2. [Figure 22-11](#) shows an example LUT entry for the Event group.

**Figure 22-11. Example Look-Up Table Entry**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 22-1. ADC Look-Up Table Field Descriptions**

| Bit   | Field              | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|--------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–13 | Reserved           | 0     | Reads return zeros, writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 12–8  | EV_EXT_CHN_MUX_SEL |       | This field defines the external analog mux select that is output from the ADC module when the Event group CURRENT_COUNT register points to this LUT entry, and when the Event group conversion is triggered with the enhanced channel selection mode enabled.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 7–5   | Reserved           | 0     | Reads return zeros, writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 4–0   | EV_INT_CHN_MUX_SEL |       | <p>This field defines the internal analog mux select that is output from the ADC module when the Event group CURRENT_COUNT register points to this LUT entry, and when the Event group conversion is triggered with the enhanced channel selection mode enabled.</p> <p>This can be a value between 0 and 31, which corresponds to the internal analog input channel number between 0 and 31. Note that this device only supports 24 input channels for ADC1 and 16 input channels for ADC2. If the application configures an unavailable channel number in the EV_INT_CHN_MUX_SEL field, the ADC will still perform the conversion and the result will be indeterminate.</p> |

Now suppose that the application has enabled the enhanced channel selection mode for Group1 with the G1\_MAX\_COUNT register configured to be 3. Also suppose that the application has programmed the Group1 LUT as shown in [Figure 22-12](#). Now suppose that the application triggers Group1 conversions by writing 0x80000001 to ADG1SEL, that is, bits 0 and 31 are set and all others are zeros. The ADC conversions will proceed in the following sequence:

- **Input Channel Selection**

The initial value of G1\_CURRENT\_COUNT is 0, which is used as the index into the Group1 LUT. The row 0 of Group1's LUT has values of 1 for the G1\_EXT\_CHN\_MUX\_SEL and a value of 1 for the G1\_INT\_CHN\_MUX\_SEL. The 5-bit external channel id of 0b00001 is driven out on the AWM\_EXT\_SEL terminals. This selects channel 1 for all the connected external analog multiplexors, as shown in [Figure 22-12](#). The ADC module also outputs an enable signal to the external analog multiplexors via the AWM\_EXT\_ENA terminal.

Now consider the fact that the internal channel id is also configured to be 1 in row 0 of the Group1 LUT. This causes the switch for ADC's internal channel 1 (ADIN1) to be closed. All other internal ADC input switches (ADIN0, ADIN2, ADIN3, ..., ADIN31) will be open. Note that the ADIN1 input channel is actually connected to the output of an 8:1 analog multiplexor.

In effect, the ADC will convert channel 1 of the 8:1 analog multiplexor connected to the ADIN1 terminal of the microcontroller.

- **After Completion of Conversion**

Once the first conversion is completed, the CURRENT\_COUNT value of 0 is stored in the "channel id" field of the conversion result RAM of Group1 along with the actual conversion result from the ADC core. Then the G1\_CURRENT\_COUNT value of 0 is compared against the G1\_MAX\_COUNT value of 3. The values do not match, so that G1\_CURRENT\_COUNT is incremented from 0 to 1.

- **Next Channel Selection**

There are two bits set in the ADG1SEL register, so that the ADC module now uses the G1\_CURRENT\_COUNT value of 1 to index the Group1 LUT. As shown in [Figure 22-12](#), this row in Group1 LUT contains 4 as the G1\_EXT\_CHN\_MUX\_SEL and 2 as the G1\_INT\_CHN\_MUX\_SEL.

ADC input channel ADIN2 is not connected to any external analog multiplexor and is connected directly to the analog signal to be converted. Note that the ADC module still drives the AWM\_EXT\_ENA and the AWM\_EXT\_SEL (value of 4, that is, 0b00100) to all the external analog multiplexors connected to the microcontroller.

- **End of Conversion Sub-Sequence**

Once the conversion of the internal channel ADIN2 is completed, the G1\_CURRENT\_COUNT of 1 is stored in the "channel id" field of the Group1 result RAM along with the actual conversion result. This value of 1 is compared against the G1\_MAX\_COUNT value of 3. The values do not match, so that G1\_CURRENT\_COUNT is incremented from 1 to 2.

There are no more conversions required in this sub-sequence as only two bits are set in ADG1SEL.

- **Continuation on Next Group1 Trigger**

When the ADC Group1 is triggered again or if Group1 is in continuous conversion mode, the G1\_CURRENT\_COUNT of 2 is again used to index the Group1 LUT. Following the same reasoning as before, this will cause the channel 1 of the 8:1 analog multiplexor connected to ADIN1 to be converted.

Once this conversion is done, the G1\_CURRENT\_COUNT value of 2 is stored in the "channel id" field of the result RAM along with the conversion result. This still does not match the G1\_MAX\_COUNT of 3, so that G1\_CURRENT\_COUNT is now incremented from 2 to 3.

This index value of 3 is used to again convert channel ADIN2, following the same reasoning as before.

When this conversion is completed, the G1\_CURRENT\_COUNT of 3 is stored as the "channel id" field of the result RAM along with the conversion result.

Also, now this G1\_CURRENT\_COUNT value of 3 matches the G1\_MAX\_COUNT. This resets the G1\_CURRENT\_COUNT to zero.

The above sequence proceeds as described whenever Group1 is next triggered, or if Group1 is configured to be in a continuous conversion mode.

### 22.4.3 Single or Continuous Conversion Modes

The EV MODE, G1 MODE, and G2 MODE bits are used to select between either single or continuous conversion mode for each of the three groups.

#### 22.4.3.1 Single Conversion Mode

A conversion group configured to be in single-conversion mode gets serviced only once by the ADC for each group trigger. The trigger can be a software trigger as in the case of Group1 and Group2 by default, or it could be a hardware event trigger as in the case of the Event Group or Group1 or Group2.

The entire conversion sequence, from the acceptance of the group conversion request to the end of the last channel's conversion, is flagged for each group by the corresponding BUSY bit in that group's status register. After single-conversion mode is started, the BUSY bit is read as 1 until the conversion of the last channel is complete. The END bit for the group is set once all the channels in that group are converted.

For example, say channels 0, 2, 4, and 6 are selected for conversion in Group1 in single-conversion mode. When the Group1 gets serviced, the ADC will start conversion for channel 0, then channel 2, then channel 4, and then channel 6. It will then stop servicing the Group1, set the GP1 END status bit, and look to service the Event Group or the Group2, if required.

#### 22.4.3.2 Continuous Conversion Mode

A conversion group configured to be in continuous-conversion mode gets serviced by the ADC continuously. The group still needs to be triggered appropriately for the first conversion to start. The conversions are performed continuously thereafter.

The entire conversion sequence, from the acceptance of the group conversion request to the end of the last channel's conversion, is flagged for each group by the corresponding BUSY bit in that group's status register. After continuous-conversion mode is started, the BUSY bit is read as 1 as long as the continuous-conversion mode for this group is selected.

As an example, say the channels 0, 2, 4, and 6 are selected for conversion in Group1, now in continuous-conversion mode. When the Group1 gets serviced, the ADC will complete conversions for channels 0, 2, 4 and 6, and then look to service the Event Group or the Group2. Once it is done servicing the Event Group or the Group2, it will return to service the Group1 again. The Group1 does not need to be triggered again for the repeated conversion.

---

**NOTE: Configuring all conversion groups in continuous conversion mode**

All the three groups cannot operate in continuous-conversion mode at the same time. If the application program configures all three groups to be in continuous-conversion mode, the Group2 is automatically reset to single-conversion mode, and the G2 MODE bit in the ADG2MODECR register is cleared to reflect the single-conversion mode of Group2.

---

### 22.4.4 Conversion Group Freeze Capability

The ADC module has an inherent priority order between the three conversion groups. This group priority determines the order of conversion in case multiple groups are triggered. The priority of conversions between the three groups in descending order is:

1. Event Group
2. Group1
3. Group2

Examples of conversion group priority:

- If an Event Group conversion is ongoing in single conversion sequence mode and Group2 and Group1 conversions are requested, then the ADC will finish conversion of channels selected in Event Group, then switch over to converting channels selected in Group1, and then convert channels selected in Group2.
- If Group1 conversions are ongoing in continuous conversion mode and Group2 conversion is requested, then the ADC will complete converting the current channel for Group1 and switch over to converting channels selected in Group2. The new conversion request for Group2 has a higher priority than the pending continuous conversion request for Group1.

The conversion group freeze capability allows the application to override this default priority between the conversion groups. Enabling the freeze capability allows the ADC to freeze a higher-priority conversion group's conversions whenever there is a request for conversion in another (lower-priority) group.

For example, setting the FRZ EV bit in the ADEVMODECR register will allow the ADC to freeze ongoing Event Group conversions whenever there is a pending request, or a new request for a Group1 or Group2 conversion. The conversions for the Event Group will be frozen as long as the Group1 or Group2 conversions are active. Once the Group1 or Group2 conversions are completed, the Event Group conversions start from where they were frozen.

While a group's conversions are frozen, the group's STOP status bit is set. This bit is cleared once the group's conversions are restarted.

#### 22.4.5 Conversion Group Memory Overrun Option

An overrun condition occurs when the ADC module tries to store more conversion results to a group's results' memory which is already full. In this case, the ADC allows two options.

If the OVR RAM IGN bit in the group's operating mode control register (ADEVMODECR, ADG1MODECR, ADG2MODECR) is set, then the ADC module ignores the contents of the group's results' memory and wraps around to overwrite the memory with the results of new conversions.

If the OVR RAM IGN bit is not set, then the application program has to read out the group's results' memory upon an overrun condition; only then can the ADC continue to write new results to the memory.

#### 22.4.6 Response on Writing Non-Zero Value to Conversion Group's Channel Select Register

If the application writes a non-zero value to a group's channel select register while that group's conversions are already being serviced, then that group's conversions will be restarted with the new configuration programmed in the channel select registers.

The following rules apply in terms of the effect on the ADC conversion sequence:

- If the new conversion request comes from the same group as the ongoing conversion, then the ongoing conversion will be stopped in whichever stage it is in, and the new sequence of conversions will be started.
- If the new conversion request comes from a separate group, then the ongoing channel's conversion will be completed before starting the new sequence of conversions.

The following rules apply in terms of the effect on the group's results memory:

- If a group conversion is ongoing or is frozen, writing a non-zero value to the group's channel select register will also reset its results FIFO. This does not clear the contents of the results FIFO; only the ADC module is allowed to overwrite the FIFO's contents with new conversion results starting from the first location.
- If the group conversion is completed (CONV <GRP> END flag is set), or the group is not being used, then writing a non-zero value to the group's channel select register will either be reset or not depending on the value of the NoResetOnChnSel bit for that group (ADEVMODECR, ADG1MODECR, ADG2MODECR).
  - If the NoResetOnChnSel bit is 0, then the group's FIFO will be reset.
  - If the NoResetOnChnSel bit is 1, then the group's FIFO will not be reset.

## 22.4.7 Conversion Result Size on Reading: 8-bit, 10-bit, or 12-bit

Some applications do not need the full 12-bit resolution of the ADC modules on the device and can work with 8-bit or 10-bit conversion results.

### 22.4.7.1 ADC Configured in 12-bit Resolution

The mode control register for each conversion group contains a field called DATA\_FMT, which defines the format of the conversion result read out of the result RAM, when accessed as a FIFO.

The DATA\_FMT field is encoded as follows:

- If DATA\_FMT = 00, the complete 12-bit conversion result is read out of the FIFO.
- If DATA\_FMT = 01, the 12-bit conversion result is right-shifted by 2 and the resulting 10-bit result is read out of the FIFO.
- If DATA\_FMT = 10, the 12-bit conversion result is right-shifted by 4 and the resulting 8-bit result is read out of the FIFO.

This control field is not effective when the application chooses to access the conversion result memory directly. In that case, the application can choose to mask off the number of bits as required.

### 22.4.7.2 ADC Configured in 10-bit Resolution

The DATA\_FMT field is not effective in this mode and the application has the choice to read either the full 10-bit conversion result or an 8-bit conversion result. This is controlled by the 8BIT field of the group's operating mode control register.

- If 8BIT = 0, the complete 10-bit conversion result is read out of the FIFO.
- If 8BIT = 1, the 10-bit conversion result is right-shifted by 2 and the resulting 8-bit result is read out of the FIFO.

## 22.4.8 Option to Read Group Channel Id Along With Conversion Result

The ADC module allows the application program to also read out the analog input channel number along with its conversion result. This capability is enabled by setting the CHID bit in the group's operating mode control register.

If the CHID bit is not set, the bits [14-10] are forced to 00000 when the conversion results are read out from the group's results' FIFO.

If the CHID bit is set, the bits [14-10] in the group's results' memory contain the input channel number to which the conversion result belongs.

---

#### NOTE: Actual Storage of Channel Id

Regardless of whether the CHID bit is set or not, the channel number is **always stored** in the memory along with the conversion result. The CHID bit only affects whether the channel number is available with the conversion result **when the group's memory is read**. Therefore, the CHID bit for a group can be changed dynamically without affecting that group's ongoing conversions.

---

## 22.5 ADC Module Basic Interrupts

This section describes the basic interrupts generated by the ADC module.

### 22.5.1 Group Conversion End Interrupt

The ADC module sets the group's conversion end flag (EV END, G1 END, or G2 END) in that group's interrupt flag register (ADEVINTFLG, ADG1INTFLG, ADG2INTFLG) when all the channels selected for conversion in that group are converted. This causes a group conversion end interrupt to be generated if this interrupt is enabled by setting the group's END INT EN control bit (EV END INT EN, G1 END INT EN, or G2 END INT EN).

This interrupt can be easily used for conversion groups configured to be in the single-conversion mode. The application program can read out the conversion results, change the group's configuration if necessary, and restart the conversions by triggering the group from within the interrupt service routine.

For groups configured to be in continuous conversion mode, this interrupt condition is not practical as the conversions are always in progress. In this case, the Group Memory Threshold Interrupt is more practical as the application can allow a programmable number of conversion results to accumulate before interrupting the CPU.

### 22.5.2 Group Memory Threshold Interrupt

The ADC module has the ability to generate an interrupt for a fixed number of conversions for each group. A group memory threshold register determines how many conversion results must be in a group's memory region before the CPU is interrupted. This feature can be used to significantly reduce the CPU load when using interrupts for reading the conversion results.

The group's threshold register needs to be configured before the group conversions are triggered. This threshold register value behaves like a down-counter, which decrements each time the ADC writes a conversion result to this group's memory. This counter is incremented each time the application program reads a conversion result from the results' memory by accessing the FIFO queue. Simultaneous read (by application program) and write (by ADC module) operations from the group's results' memory leave the threshold counter unchanged.

The threshold counter can decrement past 0 and become negative. It always increments back to its original value when the memory region is emptied. To determine how many samples are in the memory region at a given moment, the threshold counter can be subtracted from the originally configured threshold count.

Whenever the threshold counter transitions from +1 to 0, it sets the group's threshold interrupt flag, and the CPU is interrupted if the group's threshold interrupt is enabled. The CPU is expected to clear the interrupt flag after reading the conversion results from the memory.

The interrupt flag is not set when the threshold counter stays at 0 or transitions from -1 to 0.

### 22.5.3 Group Memory Overrun Interrupt

An interrupt can be generated for each group if the number of ADC conversions for that group exceed the number of buffers allocated for that conversion group. The application program can choose to read out all the conversion results using the CPU or the DMA. Alternatively, the application program can set the group's OVR RAM IGN bit and allow the ADC module to overwrite the group's results' memory contents with new conversion results.

## 22.6 ADC Module DMA Requests

This section describes the capabilities of the ADC module to take advantage of the Platform DMA controller module. The ADC module can generate a DMA request under two conditions:

### 22.6.1 DMA Request for Each Conversion Result Written to the Results' Memory

In this mode, the ADC module will generate the first DMA request as soon as a conversion result gets written to the group's results' memory. Subsequent writes to the results' memory will cause DMA requests to be generated. This mode allows a smaller amount of ADC results' memory to suffice for an application.

This DMA request generation is enabled by setting the group's DMA EN bit in the group's DMA control register. The BLOCK XFER bit in this register must be left cleared (default) if a DMA request is desired to be generated for new results getting written to the results' memory.

### 22.6.2 DMA Request for a Fixed Number of Conversion Results

This mode is enabled by setting both the group's DMA EN and the group's BLOCK XFER bits in the group's DMA control registers.

In this mode, a DMA request will be generated for a specified number of conversion results being available in the group's results' memory. The number of conversion results desired are configured using the group's BLOCKS field in the control registers.

For example, if the BLOCK count is configured for 10, then ADC module will generate a DMA request at the end of 10th conversion. DMA controller should complete reading out 10 data before next set of 10 conversions complete.

---

**NOTE: Usage of Block DMA transfers with Threshold Interrupts**

It is not recommended to enable the block DMA transfers for a group at the same time as the group threshold interrupt. The group's BLOCKS field is essentially the same as the group's THRESHOLD field in the group's interrupt control register described in [Section 22.5.2](#).

---

## 22.7 ADC Magnitude Threshold Interrupts

The ADC allows up to three magnitude threshold interrupts to be generated. The comparison parameters are programmed via the Magnitude Threshold Control Register (ADMAGINTxCR).

### 22.7.1 Magnitude Threshold Interrupt Configuration

The following fields are configurable for each of the three available magnitude threshold interrupts:

1. CHN/THR COMP: Specifies whether to compare two channels' conversion results, or to compare a channel's conversion result to a programmable threshold value. A value of 0 will select the programmable threshold to be compared, and a value of 1 will select the conversion result of the channel identified by the COMP CHID field to be compared.
2. MAG CHID: Specifies the channel number from 0 to 23 whose conversion result needs to be monitored.
3. COMP CHID: Specifies the channel number from 0 to 23 whose last conversion result is used for the comparison with the conversion result of the channel being monitored.
4. MAG THRESHOLD: Specifies the value for comparison with the conversion result of the channel identified by the MAG CHID field.
5. CMP GE/LT: Specifies whether the conversion result of the channel identified by MAG CHID is compared to be "greater than or equal to", or "less than" the reference value. The reference value can be the conversion result of another channel identified by the COMP CHID field, or it could be a threshold value specified in the MAG THRESHOLD field. A value of 0 in the CMP GE/LT field indicates a "less than" comparison and a value of 1 indicates a "greater than or equal to" comparison.

### 22.7.2 Magnitude Threshold Interrupt Comparison Mask Configuration

There is also a separate comparison mask register (ADMAGINTxMASK) for each of the three magnitude threshold interrupts. This register is used to specify the bits that are masked off for the sake of the comparison. For example, the lower 4 bits of the conversion result can be masked off by writing 0xf to the interrupt comparison mask register, allowing a gross comparison to be made. By default, the full 10/12-bit conversion results are compared.

### 22.7.3 Magnitude Threshold Interrupt Enable / Disable Control

Each of the three magnitude interrupts also have separate interrupt enable set (ADMAGTHRINTENASET) and clear (ADMAGTHRINTENACLR) registers. These are used to respectively enable and disable that particular magnitude threshold interrupt from being generated. To enable a magnitude threshold interrupt, write a 1 to the corresponding bit of the interrupt enable set register. Conversely, to disable a magnitude threshold interrupt, write a 1 to the corresponding bit of the interrupt enable clear register.

### 22.7.4 Magnitude Threshold Interrupt Flags

There is a separate Magnitude Interrupt Flag register (ADMAGINTFLG) that holds the flags for these three interrupts. This flag gets set whenever the comparison condition for the corresponding interrupt is met. A magnitude threshold interrupt is generated if the corresponding flag is set inside the flag register, and the interrupt generation is enabled. This flag can be cleared by writing a 1 to the flag or by reading from the interrupt offset register in case of this interrupt being the current highest-priority pending interrupt.

### 22.7.5 Magnitude Threshold Interrupt Offset Register

It is possible to have multiple magnitude threshold interrupts pending at the same time. The magnitude threshold interrupt offset register (ADMAGINTOFF) holds the index of the currently pending highest priority magnitude threshold interrupt. The magnitude threshold interrupt 1 has the highest priority while the magnitude threshold interrupt 3 has the lowest priority. This is a read-only register and returns zeros if none of the magnitude threshold interrupts are pending. Writes to this register have no effect.

A read from this register updates the register to the next highest-priority pending magnitude threshold interrupt. This read also clears the corresponding flag from the magnitude threshold interrupt flag register. However, a read from the magnitude threshold interrupt offset register in emulation mode does not affect the interrupt flag register or the interrupt offset register.

## 22.8 ADC Special Modes

The ADC module supports some special modes for diagnostics and power saving purposes.

### 22.8.1 ADC Error Calibration Mode

The application program can activate a calibration sequence any time self-test mode is disabled (SELF TEST = 0). This calibration sequence includes the conversion of an embedded calibration reference voltage followed by the calculation of an offset error correction value.

#### NOTE: Disable Self-Test Mode Before Calibration

To avoid errors during the calibration operation, self-test mode must *not* be enabled during a calibration sequence. In addition, to ensure accurate results, calibrate the ADC in an environment with minimum noise.

Calibration mode is enabled by setting the CAL EN bit (ADCALCR.0). The application needs to ensure that no conversion group is being serviced when the calibration mode is enabled.

The input multiplexor gets disabled and only the reference voltage is connected to the ADC core input. Switch S5 of Figure 22-13 is opened. In addition, the digital result issued from a conversion is output from the ADC core to the calibration and offset error correction register, ADCALR. The ADC results' memory is not affected by the calibration conversion.

When calibration mode is disabled, the ADC can be configured for normal conversions.

**Figure 22-13. Self-Test and Calibration Logic**

#### 22.8.1.1 Calibration Conversion

The calibration conversion also needs to meet the minimum sampling time specification for the ADC. This value is typically 1  $\mu$ s. The Event Group sample time register (ADEVSAMP) is used to specify the number of ADCLK cycles for the calibration conversion.

The BRIDGE EN and HILO bits (ADCALCR.9:8) control the voltage to the calibration reference device shown in Figure 22-15. The positions of the switches in calibration mode are listed in Table 22-2.

**Table 22-2. Calibration Reference Voltages<sup>(1)</sup>**

| CAL EN | BRIDGE EN | HILO | S1 | S2 | S3 | S4 | S5 | Reference Voltage                                 |
|--------|-----------|------|----|----|----|----|----|---------------------------------------------------|
| 1      | 0         | 0    | 1  | 0  | 1  | 0  | 0  | $(AD_{REFHI} * R1 + AD_{REFLO} * R2) / (R1 + R2)$ |
| 1      | 0         | 1    | 0  | 1  | 0  | 1  | 0  | $(AD_{REFLO} * R1 + AD_{REFHI} * R2) / (R1 + R2)$ |
| 1      | 1         | 0    | 0  | 1  | 1  | 0  | 0  | $AD_{REFLO}$                                      |
| 1      | 1         | 1    | 1  | 0  | 0  | 1  | 0  | $AD_{REFHI}$                                      |
| 0      | X         | X    | 0  | 0  | 0  | 0  | 1  | $V_{in}$                                          |

<sup>(1)</sup> The state of the switches in this table assumes that self-test mode is not enabled.

When CAL ST (ADCALCR.16) is set, a calibration conversion is started. The voltage source selected via the bits BRIDGE EN and HILO is converted once (single conversion mode) and the digital result is returned to the calibration and correction register, ADCALR, where it can be read by the CPU. The CAL ST bit acts as a flag and must be polled by the CPU. It is held set during the conversion process and automatically clears to indicate the end of the reference voltage conversion.

**NOTE: No Interrupt for end of calibration**

The ADC does not generate an interrupt to signal the end of the calibration conversion. The application must poll the CAL ST bit to determine the end of the calibration conversion.

After the CAL ST bit is set by the application program, it can only be reset by the end of the ongoing conversion generated by the ADC core. If the calibration conversion is interrupted (CAL EN bit is cleared), the CAL ST bit is held at 1 until a new calibration conversion has been set and completed. Setting the CAL ST bit while calibration is disabled (CAL EN = 0) has no effect; however, in this situation, setting CAL EN immediately starts a calibration conversion. When the calibration conversion is interrupted by an ADC enable (ADC EN = 0, CAL EN = 1, and CAL ST = 1), a new conversion is automatically restarted as soon as the ADC enable bit is released (ADC EN = 1).

### 22.8.1.2 Calibration and Offset Error Correction Sequences

The number of measurements and the source to measure for an ADC calibration are application dependent. The CAL ST bit must be set for each calibration source to be measured. While calibration mode is enabled, any available calibration sources can be converted according to the BRIDGE EN and HILO bits (see Table 22-2). The digital results of the calibration measurements should be read from ADCALR by the application after each reference conversion so that a correction value can be computed and written back into ADCALR.

When the application has the necessary calibration data, it should compute the offset error correction value and load it into the calibration and correction register, ADCALR. After the CAL EN bit is cleared, normal conversion mode restarts, continuing from where it was frozen, but with the addition of self-correction data.

In normal mode, the self-correction system adds the correction value stored in ADCALR to each digital result before it is written to the respective group's FIFO.

The basic calibration routine is as follows:

1. Enable calibration via CAL EN (ADCALCR.0).
2. Select the voltage source via BRIDGE EN and HILO (ADCALCR.9:8).
3. Start the conversion with CAL ST (ADCALCR.16).
4. Wait for CAL ST to go to 0.
5. Get the results from ADCALR and save to memory.
6. Loop to step 2 until the calibration conversion data is collected for the desired reference voltages.
7. Compute the error correction value using calibration data saved in memory.
8. Load the ADCALR register with the 2s complement of the computed error correction value.
9. Disable calibration mode.

At this point, the ADC can be configured for normal operation, and it corrects each digital result with the error correction value loaded in ADCALR.

---

**NOTE: Prevent ADC Calibration Data From Being Overwritten**

In calibration mode, the conversion result is written to ADCALR which overwrites any previous calibration data; therefore, the ADCALR register must be read before a new conversion is started.

---

For no correction, a value of 0x0000 must be written to ADCALR. In noncalibration mode, the ADCALR register can be read and written. Any value written to ADCALR in normal mode (CAL EN = 0) is added to each digital result from the ADC core.

### 22.8.1.3 Mid-Point Calibration

Because of its connections to the ADC's reference voltage (VrefHi, VrefLo), the precision of the calibration reference is voltage independent. On the other hand, the accuracy of the switched bridge resistor (R1 & R2) relies on the manufacturing process deviation. Consequently, the mid-point voltage's accuracy can be affected due to the imperfections in the two resistors (expected mismatch error is around 1.5%).

The switched reference voltage device has been specially designed to support a differential measurement of its mid-point voltage. This ensures the accuracy of the mid-point reference, and hence the efficiency of the calibration.

The differential mid-point calibration is software controlled; the algorithm (voltage source measurements and associated calculation) is inserted within the calibration software module included in the application program.

The basic differential mid-point calibration flow is illustrated here after:

1. The application program connects the voltage VrefHi to R1 and VrefLo to R2, (BRIDGE\_EN=0, HILO=0), launches a conversion of the input voltage V(cal1), and stores the digital result D(cal1) into the memory.
2. Then the application program switches the voltage VrefHi to R2 and VrefLo to R1 (BRIDGE\_EN=0, HILO=1), converts this new input voltage V(cal2) and again stores the issued digital result D(cal2) into the memory.
3. The actual value of the real middle point is obtained by computing the average of these two results.  $[D(cal1)+D(cal2)] / 2$ ; [Figure 22-14](#) below summarizes the mid-point calibration flow.

**Figure 22-14. Mid-point Value Calculation**

$$V(\text{cal1}) = [V_{\text{REFHI}} \cdot R1 + V_{\text{REFLO}} \cdot R2] / (R1 + R2)$$

$$V(\text{cal2}) = [V_{\text{REFLO}} \cdot R1 + V_{\text{REFHI}} \cdot R2] / (R1 + R2)$$

$$[V(\text{cal1}) + V(\text{cal2})] / 2 = (V_{\text{REFHI}} - V_{\text{REFLO}}) / 2$$

## 22.8.2 ADC Self-Test Mode

The ADC module supports a self-test mode which can be used to detect an open or a short on the ADC input channels. Self-test mode is enabled by setting the SELF TEST bit (ADCALCR.24). Any conversion type (continuous or single conversion, freeze enabled or non-freeze enabled, interrupts enabled or disabled) can be performed in this mode.

In normal mode, setting the self-test mode while a conversion sequence is in process can corrupt the current channel conversion results. However, the next channel in the sequence is converted correctly during the additional self-test cycle. The logic associated with both self-test and calibration is shown in Figure 22-15.

**Figure 22-15. Self-Test and Calibration Logic**

In self-test mode, a test voltage defined by the HILO bit (ADCALCR.8) is provided to the ADC core input through a resistor (see Table 22-3). To change the test source, this bit can be toggled before any single conversion mode request. Changing this bit while a conversion is in progress can corrupt the results if the source switches during the acquisition period.

Note that the switch S5 shown in the above figure is only for the purpose of explaining the self-test sequence. There is no physical switch.

**Table 22-3. Self-Test Reference Voltages<sup>† (1)</sup>**

| SELF TST | HILO | S1 | S2 | S3 | S4 | S5 | Reference Voltage                     |
|----------|------|----|----|----|----|----|---------------------------------------|
| 1        | 0    | 0  | 1  | 1  | 0  | 1  | ADREFLO via R1    R2 connected to Vin |
| 1        | 1    | 1  | 0  | 0  | 1  | 1  | ADREFHI via R1    R2 connected to Vin |
| 0        | X    | 0  | 0  | 0  | 0  | 1  | Vin                                   |

<sup>(1)</sup> Switches refer to Figure 22-15.

Conversions in self-test mode are started just as they are in the normal operating mode (see Section 22.3.6). The conversion starts according to the configuration set in the three mode control registers (ADEVMODECR, ADG1MODECR, ADG2MODECR) and the sampling time control registers (ADEVSAMP, ADG1SAMP, ADG2SAMP). The acquisition time for each conversion in self-test mode is extended to twice the normal configured acquisition time. The selected reference voltage and the input voltage from the ADINx input channel are both connected to the ADC internal sampling capacitor throughout this extended acquisition period. Figure 22-16 shows the self-test mode timing when the ADREFLO is chosen as the reference voltage for the self-test mode conversion. It also assumes an external capacitor connected to the ADC input channel.

**Figure 22-16. Timing for Self-Test Mode**

### 22.8.2.1 Use of Self-Test Mode to Determine Open/Short on ADC Input Channels

The following sequence needs to be used to deduce the ADC pin status:

- Convert the channel with self test enabled and with the reference voltage as Vreflo. Store the conversion result, say Vd.
- Convert the channel with self test enabled and with the reference voltage as Vrefhi. Store the conversion result, say Vu.
- Convert the channel with self test disabled. Store the conversion result, say Vn.

The results can be interpreted using the following table.

**Table 22-4. Determination of ADC Input Channel Condition**

| Normal Conversion Result, Vn | Self-test Conversion Result, Vu | Self-test Conversion Result, Vd | Pin Condition           |
|------------------------------|---------------------------------|---------------------------------|-------------------------|
| Vn                           | $Vn < Vu < AD_{REFHI}$          | $AD_{REFLO} < Vd < Vn$          | Good                    |
| $AD_{REFHI}$                 | $AD_{REFHI}$                    | approx. $AD_{REFHI}$            | Shorted to $AD_{REFHI}$ |
| $AD_{REFLO}$                 | approx. $AD_{REFLO}$            | $AD_{REFLO}$                    | Shorted to $AD_{REFLO}$ |
| Unknown                      | $AD_{REFHI}$                    | $AD_{REFLO}$                    | Open                    |

### 22.8.3 ADC Power-Down Mode

This is an inactive mode in which the clocks to the ADC module are stopped leaving the module in a static state. The clock to the ADC core (ADCLK) is stopped whenever there are no ongoing conversions. This is the clock-gating implementation requirement. Also, the ADC module places the ADC core into the power down mode such that there is minimal current drawn from the ADC operating and reference supplies.

#### 22.8.3.1 Powering Down Just The ADC Core

The ADC core can be individually powered down without stopping the clocks to the ADC module. This can be done by setting the POWERDOWN bit of the ADC Operating Mode Control Register (ADOPMODECR.3). Whenever a conversion is required the POWERDOWN bit must be cleared, and a minimum time  $t_{d(PU-ADV)}$ , (see the specific device data sheet for actual value) has to be allowed before starting a new conversion. This wait must be implemented in the application software.

### 22.8.3.2 Enhanced Power-Down Mode

A bit in the ADC operating mode control register, IDLE PWRDN (ADOPMODECR.4) enables the enhanced power-down mode of the ADC.

Once this bit is set, the ADC module will power down the ADC core whenever there are no more ongoing or pending ADC conversions. The ADC core will be powered down regardless of the state of the POWERDOWN bit (ADOPMODECR.3).

The ADC module releases the ADC core from power down mode as soon as a new conversion is requested. The ADC logic state machine then has to wait for at least  $t_{d(PU-ADV)}$  (see the device data sheet for actual value) before starting a new conversion. The IDLE PWRDN bit will remain set at all times. The logic state machine can use this bit to determine that it needs to wait for a programmable number of VCLK cycles before it allows the input channel to be sampled. This time is configured by the ADC Power Up Delay Control register (ADPWRUPDLYCTRL).

If IDLE PWRDN is not set, the ADC module does not wait for any additional delay before sampling the input channel and the application software has to take account of this required delay.

### 22.8.3.3 Managing Clocks to the ADC Module

The clock to the ADC module can be turned off via the appropriate Peripheral Central Resource (PCR) controller PSPWRDNSET register (check the specific device datasheet to identify the register and the bit to be set). If a conversion is ongoing when this bit is set, the ADC module will wait until the current conversion completes before allowing the ADC module clock to be stopped.

### 22.8.4 ADC Sample Capacitor Discharge Mode

This mode allows the charge on the ADC core's internal sampling capacitor to be discharged before starting the sampling phase of the next channel.

**Figure 22-17. Timing for Sample Capacitor Discharge Mode**

The ADC Sample Cap Discharge Mode is enabled by setting the SAMP DIS EN bit of the group's ADSAMPDISEN register. A discharge period for the sampling capacitor is added before the sampling period for each channel as shown in Figure 22-17. The duration of this discharge period is configurable via the corresponding group's SAMP DIS CYC field in the ADSAMPDISEN register. The discharge time is specified in terms of number of ADCLK cycles.

During the sample capacitor discharge period, the  $V_{REFLO}$  reference voltage is connected to the input voltage terminal of the ADC core. This allows any charge collected on the sampling capacitor from the previous conversion to be discharged to ground. The  $V_{REFLO}$  reference voltage is usually connected to ground.

## 22.9 ADC Results' RAM Special Features

The following sections describe some of the special features supported by the ADC module to enhance the results' RAM testability and integrity.

### 22.9.1 ADC Results' RAM Auto-Initialization

The ADC module allows the application to auto-initialize the ADC results' RAM to all zeros. The application must ensure that the ADC module is not in any of the conversion modes before triggering off the auto-initialization process.

The auto-initialization sequence is as follows:

1. Enable the global hardware memory initialization key by programming a value of 1010 to the bits [3-0] of the MINITGCR register of the System module.
2. Set the control bit for the ADC results' RAM in the MSINENA System module register. The bit 8 of the MSINENA register is used to control the initialization of the ADC1 results' RAM, while bit 14 controls the initialization of the ADC2 results' RAM. This starts the initialization process. The BUF INIT ACTIVE flag in the ADC module ADBNDEND register will get set to reflect that the initialization is ongoing.
3. When the memory initialization is completed, the corresponding status bit in the MINISTAT register will be set. Also, the BUF INIT ACTIVE flag will get cleared.

### 22.9.2 ADC Results' RAM Test Mode

In the defined conversion modes of the ADC, the application can only read from the ADC results' RAM. Only the ADC module is allowed to write to the results' RAM. A special test mode is defined to allow the application to also write into the ADC results' RAM - this mode is the ADC Results' RAM Test Mode. Only 32-bit reads and writes are allowed to the ADC results' RAM in this test mode.

---

**NOTE: Contention on access to ADC Results' RAM**

The ADC module cannot handle a contention between the application write to the results' RAM and the ADC writing a conversion result to the results' RAM. The application must ensure that the ADC is not likely to write a new conversion result to the results' RAM when the ADC Results' RAM Test Mode is enabled.

---

The ADC Results' RAM Test Mode is enabled by setting the RAM TEST EN bit in the ADC OP MODE CR.

### 22.9.3 ADC Results' RAM Parity

The below shows the ADC Results' RAM parity control registers.

Parity checking is implemented using parity on a per-half word basis for the ADC RAM. That is, there is one parity bit for 16 bits of the ADC RAM. The polarity of the ADC RAM parity is controlled by the DEVCR1 register in the system module (address = 0xFFFFFDC). The parity checking is enabled by the ADPARCR register. After reset, the parity checking is disabled and must be enabled if parity protection is required.

During a read access, the parity is calculated based on the data read from the ADC RAM and compared with the good parity value stored in the parity bits. If any word fails the parity check then the ADC generates an error signal hooked up to the Error Signaling Module (ESM). The ADC RAM address which generated the parity error is captured for host system debugging, and is frozen from being updated until it is read by the application.

#### Testing the Parity Checking Mechanism:

To test the parity checking mechanism itself, the parity RAM is made writable by the CPU in a special test mode. This is done by a control bit called TEST in the AD PAR CR register. Once this bit is set, the parity bits are mapped to an address starting at an address offset of 4KB from the base address of the ADC RAM. See [Figure 22-18](#). The CPU can now manually insert parity errors. Note that the ADC RAM only supports 32-bit accesses.

**Figure 22-18. ADC Memory Map in Parity Test Mode**

## 22.10 ADEVt Pin General Purpose I/O Functionality

The AD1EVT pin for ADC1 and AD2EVT pin for ADC2 can be configured as general-purpose I/O signals. The following sections describe the different ways in which the application can configure the ADxEVT pins.

### 22.10.1 GPIO Functionality

Figure 22-19 illustrates the GPIO functionality of the ADxEVT pin.

**Figure 22-19. GPIO Functionality of ADxEVT**

Once the device power-on reset is released, the ADC module controls the state of the ADxEVT pin.

- **Pull control:** The pull control can either be enabled or disabled by default (while system reset is active and after it is released). The actual default state of the pull control is specified in the device datasheet. The application can enable pull control by clearing the PDIS (pull control disable) bit in the ADEVTPDIS register. In this case, if the PSEL (pull select) bit in the ADEVTPSEL register is set, the pin will have a pull-up. If the PSEL bit is cleared, the pin will have a pull-down. If the PDIS bit is set in the control register, there is no pull-up or pull-down on the pin.

---

**NOTE: Pull Behavior when ADxEVT is configured as output**

If the ADxEVT pin is configured as output, then the pulls are disabled automatically. If the pin is configured as input, the pulls are enabled or disabled depending on bit PDIS in the pull disable register ADEVTPDIS.

---

- **Output buffer:** The ADxEVT pin can be driven as an output pin if the ADEVTDIR bit is set in the pin direction control register.
- **Open-Drain Feature:** The open drain output capability is enabled via the ADEVTPDR control register. The ADxEVT pin must be also configured to be an output pin for this mode.
  - The output buffer is enabled if a low signal is being driven on to the pin.
  - The output buffer is disabled if a high signal is being driven on to the pin.

## 22.10.2 Summary

The behavior of the output buffer, and the pull control is summarized in [Table 22-5](#). The input buffer for the ADxEVT pins are enabled once the device power-on reset is released.

**Table 22-5. Output Buffer, and Pull Control Behavior for ADxEVT as GPIO Pins <sup>(1)</sup>**

| System Reset Active? | Pin Direction (DIR) | Pull Disable (PDIS) | Pull Select (PSEL) | Pull Control | Output Buffer |
|----------------------|---------------------|---------------------|--------------------|--------------|---------------|
| Yes                  | X                   | X                   | X                  | Enabled      | Disabled      |
| No                   | 0                   | 0                   | 0                  | Pull down    | Disabled      |
| No                   | 0                   | 0                   | 1                  | Pull up      | Disabled      |
| No                   | 0                   | 1                   | 0                  | Disabled     | Disabled      |
| No                   | 0                   | 1                   | 1                  | Disabled     | Disabled      |
| No                   | 1                   | X                   | X                  | Disabled     | Enabled       |

(1)

- X = Don't care
- DIR = 0 for input, 1 for output
- PDIS = 0 for enabling pull control, 1 for disabling pull control
- PSEL = 0 for pull-down functionality, 1 for pull-up functionality

## 22.11 ADC\_CONTROL Registers

[Table 22-6](#) lists the memory-mapped registers for the ADC\_CONTROL. All register offset addresses not listed in [Table 22-6](#) should be considered as reserved locations and the register contents should not be modified.

**Table 22-6. ADC\_CONTROL REGISTERS**

| Offset | Acronym    | Register Name                                   | Section                         |
|--------|------------|-------------------------------------------------|---------------------------------|

| 2   | EV_SBIT        | R/W  | 0h    | <p>Event Group 8-bit result mode. This bit allows the Event Group conversion results to be read out in an 8-bit format. This bit only applies to the read from FIFO mode. The lower 2 bits of the 10-bit conversion result are discarded and the upper 8 bits are shifted right two places to form the 8-bit conversion result.</p> <p>Any operation mode:</p> <p>0h = The Event Group conversion result is read out as a 10-bit value in the read from Event Group FIFO mode.</p> <p>1h = The Event Group conversion result is read out as an 8-bit value in the read from Event Group FIFO mode.</p>                                                                                                                                                                                                                                                                                                                  |
| 1   | EV_MODE        | R/W  | 0h    | <p>Event Group Conversion Mode. This bit defines whether the input channels selected for conversion in the Event Group are converted only once per trigger, or are continuously converted.</p> <p>Any operation mode:</p> <p>0h = The channels selected for conversion in the Event Group are converted only once when the selected event trigger condition occurs.</p> <p>1h = The channels selected for conversion in the Event Group are converted continuously when the selected event trigger condition occurs.</p>                                                                                                                                                                                                                                                                                                                                                                                                |
| 0   | FRZ_EV         | R/W  | 0h    | <p>Event Group Freeze Enable. This bit allows an Event Group conversion sequence to be frozen if a Group1 or a Group2 conversion is requested. The Event Group conversion is kept frozen until the Group1 or Group2 conversion is active, and continues from where it was frozen once the Group1 or Group2 conversions are completed.</p> <p>While the Event Group conversion is frozen, the EV_STOP status flag in the ADEVSR register indicates that the Event Group conversions have stopped. This bit gets cleared when the Event Group conversions resume.</p> <p>Any operation mode:</p> <p>0h = Event Group conversions cannot be frozen. All the channels selected for conversion in the Event Group are converted before the ADC can switch over to servicing any other conversion group.</p> <p>1h = Event Group conversions are frozen whenever there is a request for conversion from Group1 or Group2.</p> |

### 22.11.6 ADG1MODECR Register (offset = 14h) [reset = 0h]

ADG1MODECR is shown in Figure 22-25 and described in Table 22-12.

**Figure 22-25. ADG1MODECR Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 22-12. ADG1MODECR Register Field Descriptions**

| Bit   | Field             | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| 16    | No_Reset_on_ChSel | R/W  | 0h    | No Group1 Results Memory Reset on New Channel Select. This bit determines whether the group1 results RAM is reset whenever a non-zero value is written to the group1 channel select register. If the group1 conversions are ongoing (active or frozen), then writing a nonzero value to the group1 channel select register will always reset the group1 results RAM.<br>Any operation mode:<br>0h = Group1 results RAM is reset when a non-zero value is written to group1 channel select register, even if group1 conversions are completed.<br>1h = Group1 results RAM is not reset when a non-zero value is written to group1 channel select register, and group1 conversions are completed.                                                                                                                                                                                                                          |
| 15-10 | RESERVED          | R    | 0h    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 9-8   | G1_DATA_FMT       | R/W  | 0h    | Group1 Read Data Format. This field is only applicable when the ADC module is configured to be in the 12-bit resolution mode. This field is reserved when the module is configured as a 10-bit ADC module. This field determines the format in which the conversion results are read out of the group1 results RAM when using the FIFO interface, that is, when reading from the ADG1BUFFER or ADG1EMUBUFFER locations.<br>Any operation mode:<br>0h = Conversion results are read out in full 12-bit format. This is the default mode.<br>1h = Conversion results are read out in 10-bit format. Bits 11-2 of the 12-bit conversion result are returned as the 10-bit conversion result.<br>2h = Conversion results are read out in 8-bit format. Bits 11-4 of the 12-bit conversion result are returned as the 8-bit conversion result.<br>3h = Reserved. The full 12-bit conversion result is returned if programmed. |

**Table 22-12. ADG1MODECR Register Field Descriptions (continued)**

| Bit | Field          | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----|----------------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | G1_CHID        | R/W  | 0h    | <p>Enable Channel Id for the Group1 conversion results to be read. This bit only affects the read from FIFO mode. The ADC always stores the channel id in the results RAM. Any 16-bit read performed in the read from RAM mode will return the 5-bit channel id along with the 10-bit conversion result.</p> <p>Any operation mode:</p> <p>0h = Bits 14-10, the channel id field, of the data read from the Group1 results FIFO is read as 00000b.</p> <p>1h = Bits 14-10, the channel id field, of the data read from the Group1 results FIFO contains the number of the ADC analog input to which the conversion result belongs.</p>                                                                                                                     |
| 4   | OVR_G1_RAM_IGN | R/W  | 0h    | <p>This bit allows the ADC module to overwrite the contents of the Group1 results memory under an overrun condition.</p> <p>Any operation mode:</p> <p>0h = The ADC cannot overwrite the contents of the Group1 results memory. When an overrun of this memory occurs, the software needs to read out all the contents of this memory before the ADC is able to write a new conversion result for the Group1.</p> <p>1h = When an overrun of the Group1 results memory occurs, the ADC proceeds to overwrite the contents with any new conversion results for the Group1, starting with the first location in this memory.</p>                                                                                                                             |
| 3   | G1_HW_TRIG     | R/W  | 0h    | <p>Group1 Hardware Triggered. This bit allows the Group1 to be hardware triggered. The Group1 is software triggered by default. For more details on how to trigger a conversion group, refer to <a href="#">Section 22.3.6</a>.</p> <p>Any operation mode:</p> <p>0h = The Group1 is software-triggered. A Group1 conversion starts whenever the Group1 channel select register (ADG1SEL) is written with a non-zero value.</p> <p>1h = The Group1 is hardware-triggered. A Group1 conversion starts whenever the Group1 channel select register has a non-zero value, and the specified hardware trigger occurs. The hardware trigger for the Group1 is specified in the Group1 Trigger Source register (ADG1SRC).</p>                                    |
| 2   | G1_SBIT        | R/W  | 0h    | <p>Group1 8-bit result mode. This field is only applicable when the ADC module is configured to be in the 10-bit resolution mode. This field is reserved when the module is configured as a 12-bit ADC module. This bit allows the Group1 conversion results to be read out in an 8-bit format. This bit only applies to the read from FIFO mode. The lower 2 bits of the 10-bit conversion result are discarded and the upper 8 bits are shifted right two places to form the 8-bit conversion result.</p> <p>Any operation mode:</p> <p>0h = The Group1 conversion result is read out as a 10-bit value in the read from Group1 FIFO mode.</p> <p>1h = The Group1 conversion result is read out as an 8-bit value in the read from Group1 FIFO mode.</p> |
| 1   | G1_MODE        | R/W  | 0h    | <p>Group1 Conversion Mode. This bit defines whether the input channels selected for conversion in the Group1 are converted only once, or are continuously converted.</p> <p>Any operation mode:</p> <p>0h = The channels selected for conversion in the Group1 are converted only once.</p> <p>1h = The channels selected for conversion in the Group1 are converted continuously.</p>                                                                                                                                                                                                                                                                                                                                                                     |

**Table 22-12. ADG1MODECR Register Field Descriptions (continued)**

| Bit | Field  | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----|--------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | FRZ_G1 | R/W  | 0h    | <p>Group1 Freeze Enable. This bit allows a Group1 conversion sequence to be frozen if an Event Group or a Group2 conversion is requested. The Group1 conversion is kept frozen until the Event Group or Group2 conversion is active, and continues from where it was frozen once the Event Group or Group2 conversions are completed. While the Group1 conversion is frozen, the G1_STOP status flag in the ADG1SR register indicates that the Group1 conversions have stopped. This bit gets cleared when the Group1 conversions resume.</p> <p>Any operation mode:</p> <p>0h = Group1 conversions cannot be frozen. All the channels selected for conversion in the Group1 are converted before the ADC can switch over to servicing any other conversion group.</p> <p>1h = Group1 conversions are frozen whenever there is a request for conversion from Event Group or Group2.</p> |

### 22.11.7 ADG2MODECR Register (offset = 18h) [reset = 0h]

ADG2MODECR is shown in Figure 22-26 and described in Table 22-13.

**Table 22-13. ADG2MODECR Register Field Descriptions**

| Bit   | Field             | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|-------------------|------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-17 | RESERVED          | R    | 0h    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 16    | No_Reset_on_ChSel | R/W  | 0h    | No Group2 Results Memory Reset on New Channel Select. This bit determines whether the group2 results RAM is reset whenever a non-zero value is written to the group2 channel select register. If the group2 conversions are ongoing (active or frozen), then writing a nonzero value to the group2 channel select register will always reset the group2 results RAM.<br>Any operation mode:<br>0h = Group2 results RAM is reset when a non-zero value is written to group2 channel select register, even if group2 conversions are completed.<br>1h = Group2 results RAM is not reset when a non-zero value is written to group2 channel select register, and group2 conversions are completed.                                                                                                                                                                                                                          |
| 15-10 | RESERVED          | R    | 0h    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 9-8   | G2_DATA_FMT       | R/W  | 0h    | Group2 Read Data Format. This field is only applicable when the ADC module is configured to be in the 12-bit resolution mode. This field is reserved when the module is configured as a 10-bit ADC module. This field determines the format in which the conversion results are read out of the group1 results RAM when using the FIFO interface, that is, when reading from the ADG2BUFFER or ADG2EMUBUFFER locations.<br>Any operation mode:<br>0h = Conversion results are read out in full 12-bit format. This is the default mode.<br>1h = Conversion results are read out in 10-bit format. Bits 11-2 of the 12-bit conversion result are returned as the 10-bit conversion result.<br>2h = Conversion results are read out in 8-bit format. Bits 11-4 of the 12-bit conversion result are returned as the 8-bit conversion result.<br>3h = Reserved. The full 12-bit conversion result is returned if programmed. |
| 7-6   | RESERVED          | R    | 0h    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Table 22-13. ADG2MODECR Register Field Descriptions (continued)**

| Bit | Field          | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----|----------------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | G2_CHID        | R/W  | 0h    | <p>Enable Channel Id for the Group2 conversion results to be read. This bit only affects the read from FIFO mode. The ADC always stores the channel id in the results RAM. Any 16-bit read performed in the read from RAM mode will return the 5-bit channel id along with the 10-bit conversion result.</p> <p>Any operation mode:</p> <p>0h = Bits 14-10, the channel id field, of the data read from the Group2 results FIFO is read as 00000b.</p> <p>1h = Bits 14-10, the channel id field, of the data read from the Group2 results FIFO contains the number of the ADC analog input to which the conversion result belongs.</p>                                                                                                                     |
| 4   | OVR_G2_RAM_IGN | R/W  | 0h    | <p>This bit allows the ADC module to overwrite the contents of the Group2 results memory under an overrun condition.</p> <p>Any operation mode:</p> <p>0h = The ADC cannot overwrite the contents of the Group2 results memory. When an overrun of this memory occurs, the software needs to read out all the contents of this memory before the ADC is able to write a new conversion result for the Group2.</p> <p>1h = When an overrun of the Group2 results memory occurs, the ADC proceeds to overwrite the contents with any new conversion results for the Group2, starting with the first location in this memory.</p>                                                                                                                             |
| 3   | G2_HW_TRIG     | R/W  | 0h    | <p>Group2 Hardware Triggered. This bit allows the Group2 to be hardware triggered. The Group2 is software triggered by default. For more details on how to trigger a conversion group, refer to <a href="#">Section 22.3.6</a>.</p> <p>Any operation mode:</p> <p>0h = The Group2 is software-triggered. A Group2 conversion starts whenever the Group2 channel select register (ADG2SEL) is written with a non-zero value.</p> <p>1h = The Group2 is hardware-triggered. A Group2 conversion starts whenever the Group2 channel select register has a non-zero value, and the specified hardware trigger occurs. The hardware trigger for the Group2 is specified in the Group2 Trigger Source register (ADG2SRC).</p>                                    |
| 2   | G2_SBIT        | R/W  | 0h    | <p>Group2 8-bit result mode. This field is only applicable when the ADC module is configured to be in the 10-bit resolution mode. This field is reserved when the module is configured as a 12-bit ADC module. This bit allows the Group2 conversion results to be read out in an 8-bit format. This bit only applies to the read from FIFO mode. The lower 2 bits of the 10-bit conversion result are discarded and the upper 8 bits are shifted right two places to form the 8-bit conversion result.</p> <p>Any operation mode:</p> <p>0h = The Group2 conversion result is read out as a 10-bit value in the read from Group2 FIFO mode.</p> <p>1h = The Group2 conversion result is read out as an 8-bit value in the read from Group2 FIFO mode.</p> |
| 1   | G2_MODE        | R/W  | 0h    | <p>Group2 Conversion Mode. This bit defines whether the input channels selected for conversion in the Group2 are converted only once, or are continuously converted.</p> <p>Any operation mode:</p> <p>0h = The channels selected for conversion in the Group2 are converted only once.</p> <p>1h = The channels selected for conversion in the Group2 are converted continuously.</p>                                                                                                                                                                                                                                                                                                                                                                     |

**Table 22-13. ADG2MODECR Register Field Descriptions (continued)**

| Bit | Field  | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----|--------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | FRZ_G2 | R/W  | 0h    | <p>Group2 Freeze Enable. This bit allows a Group2 conversion sequence to be frozen if an Event Group or a Group1 conversion is requested. The Group2 conversion is kept frozen until the Event Group or Group1 conversion is active, and continues from where it was frozen once the Event Group or Group1 conversions are completed.</p> <p>While the Group2 conversion is frozen, the G2_STOP status flag in the ADG2SR register indicates that the Group2 conversions have stopped. This bit gets cleared when the Group2 conversions resume.</p> <p>Any operation mode:</p> <p>0h = Group2 conversions cannot be frozen. All the channels selected for conversion in the Group2 are converted before the ADC can switch over to servicing any other conversion group.</p> <p>1h = Group2 conversions are frozen whenever there is a request for conversion from Event Group or Group1.</p> |

### 22.11.8 ADEVSRC Register (offset = 1Ch) [reset = 0h]

ADEVSRC is shown in [Figure 22-27](#) and described in [Table 22-14](#).

| 8-0   | EV_THR         | R/W  | 0h    | <p>Event Group Threshold Counter.</p> <p>Before ADC conversions begin on the Event Group, this field is initialized to the number of conversion results that the Event Group memory should contain before interrupting the CPU. This counter decrements when the ADC module writes a new conversion result to the Event Group results memory. The counter increments for each read of a conversion result from the Event Group results memory in the read from FIFO mode. The threshold counter is not affected for a direct read from the Event Group results memory. Also, a simultaneous ADC write and a CPU and DMA read from the Event Group FIFO will leave the threshold counter unchanged. In case of an Event Group Results memory overrun condition, if new conversion results are not allowed to overwrite the existing memory contents, then the Event Group threshold counter is not decremented.</p> <p>Refer to <a href="#">Section 22.5.2</a> for more details on the threshold interrupts.</p> |

### 22.11.18 ADG1THRINTCR Register (offset = 44h) [reset = 0h]

ADG1THRINTCR is shown in [Figure 22-37](#) and described in [Table 22-24](#).

**Figure 22-37. ADG1THRINTCR Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 22-24. ADG1THRINTCR Register Field Descriptions**

| Bit   | Field          | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| 8-0   | G2_THR         | R/W  | 0h    | Group2 Threshold Counter.<br>Before ADC conversions begin on the Group2, this field is initialized to the number of conversion results that the Group2 memory should contain before interrupting the CPU. This counter decrements when the ADC module writes a new conversion result to the Group2 results memory. The counter increments for each read of a conversion result from the Group2 results memory in the read from FIFO mode. The threshold counter is not affected for a direct read from the group2 results memory. Also, a simultaneous ADC write and a CPU and DMA read from the Group2 FIFO will leave the threshold counter unchanged. In case of an Group2 Results memory overrun condition, if new conversion results are not allowed to overwrite the existing memory contents, then the Grou21 threshold counter is not decremented.<br>Refer to <a href="#">Section 22.5.2</a> for more details on the threshold interrupts. |

### 22.11.20 ADEVDMACR Register (offset = 4Ch) [reset = 0h]

ADEVDMACR is shown in [Figure 22-39](#) and described in [Table 22-26](#).

### 22.11.23 ADBNDCR Register (offset = 58h) [reset = 0h]

ADBNDCR is shown in [Figure 22-42](#) and described in [Table 22-29](#).

Refer to [Section 22.3.8](#) for further details on how the conversion results are stored in the ADC results RAM.

| 24-16 | BNDA     | R/W  | 0h    | Buffer Boundary A. These bits determine the memory available for the Event Group conversion results. The memory available is specified in terms of pairs of result buffers. A total of (2 x BNDA) buffers are available in the ADC results memory for storing Event Group conversion results from 0 to 1FFh.<br>Any operation mode:<br>0h = Event Group conversions are not required. If Event Group conversions are performed with the BNDA value of zero, then the Event Group memory size will default to 1024 words. For proper usage of the ADC results memory, configure the BNDA value to be non-zero and lower than the BNDB value. |

### 22.11.31 ADEVSEL Register (offset = 78h) [reset = 0h]

ADEVSEL is shown in [Figure 22-50](#) and described in [Table 22-37](#).

Clearing ADEVSEL During a Conversion: Writing 0000h to ADEVSEL stops the Event Group conversions. This does not cause the ADC Event Group results Memory pointer or the Event Group Threshold Register to be reset. Writing A Non-Zero Value To ADEVSEL During a Conversion: Writing a new value to ADEVSEL while a Channel in Event Group is being converted results in a new conversion sequence starting immediately with the highest priority channel in the new ADEVSEL selection. This also causes the ADC Event Group Results Memory pointer to be reset so that the memory allocated for storing the Event Group conversion results gets overwritten. Care should be taken to re-program the corresponding Interrupt Threshold Counter or DMA Threshold Counter again so that correct number of conversions happen before a Threshold interrupt or Block DMA request is generated. ADC1 supports up to 24 channels and ADC2 supports up to 16 channels on the microcontroller.

### 22.11.32 ADG1SEL Register (offset = 7Ch) [reset = 0h]

ADG1SEL is shown in [Figure 22-51](#) and described in [Table 22-38](#).

Clearing ADG1SEL During a Conversion: Writing 0000h to ADG1SEL stops the Group1 conversions. This does not cause the ADC Group1 Results Memory pointer or the Group1 Threshold Register to be reset. Writing A Non-Zero Value To ADG1SEL During a Conversion: Writing a new value to ADG1SEL while a Channel in Group1 is being converted results in a new conversion sequence starting immediately with the highest priority channel in the new ADG1SEL selection. This also causes the ADC Group1 Results Memory pointer to be reset so that the memory allocated for storing the Group1 conversion results gets overwritten. Care should be taken to re-program the corresponding Interrupt Threshold Counter or DMA Threshold Counter again so that correct number of conversions happen before a Threshold interrupt or Block DMA request is generated. ADC1 supports up to 24 channels and ADC2 supports up to 16 channels on the microcontroller.

### 22.11.33 ADG2SEL Register (offset = 80h) [reset = 0h]

ADG2SEL is shown in [Figure 22-52](#) and described in [Table 22-39](#).

**Clearing ADG2SEL During a Conversion:** Writing 0000h to ADG2SEL stops the Group2 conversions. This does not cause the ADC Group2 Results Memory pointer or the Group2 Threshold Register to be reset.

**Writing A Non-Zero Value To ADG2SEL During a Conversion:** Writing a new value to ADG2SEL while a Channel in Group2 is being converted results in a new conversion sequence starting immediately with the highest priority channel in the new ADG2SEL selection. This also causes the ADC Group2 Results Memory pointer to be reset so that the memory allocated for storing the Group2 conversion results gets overwritten. Care should be taken to re-program the corresponding Interrupt Threshold Counter or DMA Threshold Counter again so that correct number of conversions happen before a Threshold interrupt or Block DMA request is generated. ADC1 supports up to 24 channels and ADC2 supports up to 16 channels on the microcontroller.

| 20-12 | G2_CHID  | R    | 0h    | Group2 Channel Id. These bits are also applicable only when the "read from FIFO" mode is used for reading the Group2 conversion results. The conversion result in the G2_DR field of this buffer is from the ADC input channel number denoted by the G2_CHID field from 1h to 17h. Any operation mode read:<br>0h = The conversion result in the G2_DR field of this buffer is from the ADC input channel 0, or the channel id mode is disabled in the Group2 mode control register (ADG2MODECR). |
| 11-0  | G2_DR    | R    | 0h    | Group2 Digital Conversion Result. The Group2 results FIFO location is aliased eight times, so that any word-aligned read from the address range D0h to EFh results in one conversion result to be read from the Group2 results memory. This allows the ARM LDMIA instruction to read out up to 8 conversion results from the Group2 results memory with just one instruction.                                                                                                                     |

### 22.11.40 ADEVEMUBUFFER Register (offset = F0h) [reset = 80000000h]

ADEVEMUBUFFER is shown in [Figure 22-59](#) and described in [Table 22-46](#).

A read from this location also gives out one conversion result from the Event Group results memory along with the EV\_EMPTY status bit and the optional channel id. However, this read will not affect any of the status flags in the Event Group interrupt flag register or the Event Group status register. This register is useful for debuggers.

### 22.11.55 ADMAGINT1MASK Register (offset = 12Ch) [reset = 0h]

ADMAGINT1MASK is shown in [Figure 22-74](#) and described in [Table 22-61](#).

The ADC module supports up to three magnitude compare interrupts.

**Figure 22-74. ADMAGINT1MASK Register**

| 0    | EV_FIFO_RESET | R/W  | 0h    | <p>ADC Event Group FIFO Reset. The application can set this bit in case of an overrun condition. This allows the ADC module to overwrite the contents of the Event Group results memory starting from the first location.</p> <p>The EV_FIFO_RESET bit will only have the desired effect when the Event Group results memory is in an overrun condition. It must be used when the data already available in the results memory can be discarded.</p> <p>If the application needs the Event Group memory to always be overwritten with the latest available conversion results, then the OVR_EV_RAM_IGN bit in the Event Group operating mode control register (ADEVMODECR) needs to be set to 1.</p> <p>1h = The ADC module resets its internal Event Group results memory pointers. Then this bit automatically gets cleared, so that the ADC module allows the Event Group results memory to be overwritten only once each time this bit is set to 1. As a result, the EV_FIFO_RESET bit will always be read as a 0.</p> |

### 22.11.65 ADG1FIFORESETCR Register (offset = 16Ch) [reset = 0h]

ADG1FIFORESETCR is shown in [Figure 22-84](#) and described in [Table 22-71](#).

| 0    | G2_FIFO_RESET | R/W  | 0h    | <p>ADC Group2 FIFO Reset. The application can set this bit in case of an overrun condition. This allows the ADC module to overwrite the contents of the Group2 results memory starting from the first location from 0 to 1.</p> <p>The G2_FIFO_RESET bit will only have the desired effect when the Group2 results memory is in an overrun condition. It must be used when the data already available in the results memory can be discarded.</p> <p>If the application needs the Group2 memory to always be overwritten with the latest available conversion results, then the OVR G2_RAM_IGN bit in the Group2 operating mode control register (ADG2MODECR) needs to be set to 1.</p> <p>1h = The ADC module resets its internal Group2 results memory pointers. Then this bit automatically gets cleared, so that the ADC module allows the Group2 results memory to be overwritten only once each time this bit is set to 1. As a result, the G2_FIFO_RESET bit will always be read as a 0.</p> |

### 22.11.67 ADEVRAMWRADDR Register (offset = 174h) [reset = 0h]

ADEVRAMWRADDR is shown in [Figure 22-86](#) and described in [Table 22-73](#).

**Figure 22-86. ADEVRAMWRADDR Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 22-73. ADEVRAMWRADDR Register Field Descriptions**

## High-End Timer (N2HET) Module

This chapter provides a general description of the High-End Timer (N2HET). The N2HET is a software-controlled timer with a dedicated specialized timer micromachine and a set of 30 instructions. The N2HET micromachine is connected to a port of up to 32 input/output (I/O) pins.

---

**NOTE:** This chapter describes a superset implementation of the N2HET module that includes features and functionality that require DMA. Since not all devices have DMA capability, consult your device-specific datasheet to determine the applicability of these features and functions to your device being used.

---

## 23.1 Features

- Programmable timer for input and output timing functions
- Reduced instruction set (30 instructions) for dedicated time and angle functions
- Up to maximum of 128 96-bit words of instruction RAM protected by parity. Check your datasheet for the actual number of words implemented.
- User defined configuration of 25-bit virtual counters for timer, event counters and angle counters
- 7-bit hardware counters for each pin allow up to 32-bit resolution in conjunction with the 25-bit virtual counters
- Up to 32 pins usable for input signal measurements or output signal generation
- Programmable suppression filter for each input pin with adjustable suppression window
- Low CPU overhead and interrupt load
- Efficient data transfer to or from the CPU memory with dedicated High-End-Timer Transfer Unit (HTU) or DMA
- Diagnostic capabilities with different loopback mechanisms and pin status readback functionality
- Hardware Angle Generator (HWAG) - (more information will be available in future User's Guide Revision)

### 23.1.1 Overview

The N2HET is a fifth-generation Texas Instruments (TI) advanced intelligent timer module. It provides an enhanced feature set compared to previous generations.

This timer module provides sophisticated timing functions for real-time applications such as engine management or motor control. The high resolution hardware channels allow greater accuracy for widely used timing functions such as period and pulse measurements, output compare, and PWMs.

The reduced instruction set, based mostly on very simple, but comprehensive instructions, improves the definition and development cycle time of an application and its derivatives. The N2HET breakpoint feature, combined with various stop capabilities, makes the N2HET software application easy to debug.

#### 23.1.1.1 Major Advantages

In addition to classic time functions such as input capture or multiple PWMs, higher-level time functions can be easily implemented in the timer program main loop. Higher-level time functions include angle driven wave forms, angle- and time-driven pulses, and input pulse width modulation (PWM) duty cycle measurement.

Because of these high-level functions, data exchanges with the CPU are limited to the fundamental parameters of the application (periods, pulse widths, angle values, etc.); and the real-time constraints for parameter communication are dramatically minimized; for example, few interrupts are required and asynchronous parameter updates are allowed.

The reduced instruction set and simple execution flow control make it simple and easy to develop and modify programs. Simple algorithms can embed the entire flow control inside the N2HET program itself. More complex algorithms can take advantage of the CPU access to the N2HET RAM. With this, the CPU program can make calculations and can modify the timer program flow by changing the data and control fields of the N2HET RAM. CPU access to the N2HET RAM also improves the debug and development of timer programs. The CPU program can stop the N2HET and view the contents of the program, control, and data fields that reside in the N2HET RAM.

Finally, the modular structure provides maximum flexibility to address a wide range of applications. The timer resolution can be selected from two cascaded prescalers to adjust the loop resolution and HR clocks. The 32 I/O pins can provide any combination of input, period or pulse capture, and output compare, including high resolution for each channel.

### 23.1.1.2 Timer Module Structure and Execution

The timer consists of a specialized micromachine that operates a reduced instruction set. Two 25-bit registers and three 32-bit registers are available to manipulate information such as time, event counts, and angle values. System performance is improved by a wide instruction format (96 bits) that allows the N2HET to fetch the instructional operation code and data in one system cycle, thus increasing the speed at which data can be processed. The typical operations performed in the ALU are additions (count), compares, and magnitude compares (higher or same).

Each instruction is made up of a 32-bit program field, a 32-bit control field and a 32-bit data field. The N2HET execution unit fetches the complete 96-bit instruction in one cycle and executes it. All instructions include a 9-bit field for specifying the address of the next instruction to be executed. Some instructions also include a 9-bit conditional address, which is used as the next address whenever a particular condition is true. This makes controlling the flow of an N2HET program inexpensive; in many cases a separate branch instruction is not required.

The interface to the host CPU is based on both communication memory and control registers. The communication memory includes timer instructions (program and data). This memory is typically initialized by the CPU or DMA after reset before the timer starts execution. Once the timer program is loaded into the memory, the CPU starts the timer execution, and typically data parameters are then read or written into the timer memory. The control registers include bits for selecting timer clock, configuring I/O pins, and controlling the timer module.

The programmer implements timer functions by combining instructions in specific sequences. For instance, a single count (CNT) instruction implements a timer. A simple PWM generator can be implemented with a two instruction sequence: CNT and compare (ECMP or MCMP). A complex time function may include many instructions in the sequence. The total timer program is a set of instructions executed sequentially, one after the other. Reaching the end, the program must roll to the first instruction so that it behaves as a loop. The time for a loop to execute is referred to as a *loop resolution clock cycle* or *loop resolution period (LRP)*. When the N2HET rolls over to the first instruction, the timer waits for the loop resolution clock to restart the execution of the loop to ensure that only one loop is executed for each loop resolution clock.

The longest path through an N2HET program must be completed within the loop resolution clock (LRP). Otherwise, the program will execute unpredictably because some instructions will not be executed each time through the loop. This effect creates a strong link between the accuracy of the timer functions and the number of functions (the number of instructions) the timer can perform. High resolution (HR) hardware timer extensions are available for each of the N2HET pins to help overcome this limitation.

The high resolution hardware timers operate from the *high resolution clock*, which may be configured for frequency multiples between 2 and 128 times the loop resolution clock frequency. This extending the resolution of timer events and measurements well beyond what is possible with only loop resolution instructions.

Most of the commonly used N2HET instructions can operate either at loop resolution or high resolution; with the restriction that for each pin at most one high resolution instruction can be executed per loop resolution period.

Certain instructions (MOV32, ADM32, ...) can modify the data fields of other instructions. This feature enables the N2HET program to implement double buffering on capture and compare functions. For example, an ECMP compare instruction can be followed by a MOV32 instruction that is conditionally executed when the ECMP instruction matches. The host CPU can update the next compare value by writing asynchronously to the data field of the MOV32 instruction instead of writing directly to the data field of the ECMP instruction. The copy from the buffer (MOV32 data field) to the compare register (ECMP data field) will occur when the MOV32 instruction is actually executed which occurs after the ECMP instruction matches its current compare value. This is the same behavior as one would expect from a double buffered hardware compare register.

Other instructions (MOV64, RADM64) can modify both the control and data fields of other instructions. This allows the N2HET to implement toggle functionality. For example, an ECMP instruction can be followed by a pair of MOV64 instructions. The MOV64 instruction updates the data field of the ECMP instruction to implement the double buffering behavior. But it also updates the control field of the ECMP instruction which allows it to change things like pin action and the conditional address. If one MOV64 instruction configures the ECMP pin action to SET while the second changes it to CLEAR, and the two MOV64 instructions update the conditional address to point to each other, then a single ECMP instruction can be used to toggle a pin each time the compare match occurs.

### 23.1.1.3 Performance

Most instructions execute in one cycle, but a few take two or three cycles.

The N2HET can generate many complex output waveforms without CPU interrupts. Where special algorithms are needed following a specific event (for example, missing teeth or a short/long input signal), a minimal number of interrupts to the CPU are needed freeing the CPU for other tasks.

### 23.1.1.4 N2HET Compared to NHET

N2HET Enhancements from NHET include:

- Eight new instructions: ADD, ADC, SUB, SBB, AND, OR, XOR, RCNT
- Full set of ALU flags Carry (C), Negative (N), Zero (Z), Overflow (V)
- Branch instruction (BR) extended to support signed and unsigned arithmetic comparison conditions
- Two additional 32-bit temporary working registers R, S.
- New HETAND register for AND-Sharing of High Resolution structure between pairs of pins
- Improved high resolution PCNT instruction

### 23.1.1.5 NHET and N2HET Compared to HET

Compared to the HET module, the N2HET contains all of the enhancements described in [Section 23.1.1.4](#) plus the following additional enhancements:

- New Interrupt Enable Set and Clear registers
- Capability to generate requests to the DMA module or the HET Transfer Unit (HTU) including new Request Enable Set and Clear registers
- NHET RAM parity error detection
- Suppression filters for each of the 32 I/O channel and control register to configure the limiting frequency and counter clock
- Enhanced edge detection hardware that does not rely on the previous bit field in the control word of the NHET instruction.
- The next, conditional and remote addresses are extended from 8 to 9 bits
- The loop resolution data fields are extended from 20 to 25 bits
- The high resolution data fields are extended from 5 to 7 bits
- Instructions with an adequate condition are able to specify the number of the request line, which triggers either the HET Transfer Unit (HTU) or the DMA module
- The CNT instruction provides a bit, which allows to configure either an equal comparison or a greater or equal comparison when comparing the selected register value with the Max-value
- The MOV32 instruction provides a new bit. If set to one the MOV32 will only perform the move, when the Z-flag is set. If set to zero the MOV32 will perform the move whenever it is executed (independent on the state of the Z-flag)
- There is a new instruction WCAPE, which is a combination of a time stamp and an edge counter
- New Open Drain, Pull Disable, and Pull Select registers

#### 23.1.1.6 Instructions Features

The N2HET has the following instructions features:

- N2HET uses a RISC-based specialized timer micromachine to carry out a set of 30 instructions
- Instructions are implemented in a Very Long Instruction Word (VLIW) format (96 bits wide)
- The N2HET program execution is self-driven by external or internal events, branching to special routines based on input edges or output compares
- Instructions point to the next instruction executed, eliminating the need for a program counter
- Several instructions can change the program flow based on internal or external conditions

#### 23.1.1.7 Program Usage

The N2HET instructions/program can be assembled with the N2HET assembler. The assembler generates a C-structure which can be included into the main application program. The application has to copy the content of the structure into the N2HET RAM, set up necessary registers and start the N2HET program execution. In addition to the C-structure, the assembler generates also a header file which makes it easy for the main application to access the different instructions and change for example the duty cycle of a PWM or read out the captured value of a specific signal edge.

#### 23.1.2 Block Diagram

The N2HET module (see [Figure 23-1](#)) comprises four separate components:

- Host interface
- N2HET RAM
- Specialized timer micromachine
- I/O control (the N2HET is attached to an I/O port of up to 32 pins)

Figure 23-1. N2HET Block Diagram

## 23.2 N2HET Functional Description

The N2HET contains RAM into which N2HET code is loaded. The N2HET code is run by the specialized timer micromachine. The host interface and I/O control provide an interface to the CPU and external pins respectively.

### 23.2.1 Specialized Timer Micromachine

The N2HET has its own instruction set, detailed in [Section 23.5.1](#). The timer micromachine reads each instruction from the N2HET RAM. The program and control fields contain the instructions for how the specialized timer micromachine executes the command. For most instructions, the data field stores the information that needs to be manipulated.

The specialized timer micromachine executes the instructions stored in the N2HET RAM sequentially. The N2HET program execution is self-driven by external or internal events. This means that input edges or output compares may force the program to branch to special routines using a conditional address.

[Figure 23-2](#) shows some of the major operations that the N2HET can carry out, namely compares, captures, angle functions, additions, and shifts. The N2HET contains five registers (A, B, R, S, and T) used to hold compare or counter values and are used by the N2HET instructions. Data may be taken from the registers or the data field for manipulation; likewise, the data may be returned to the registers or the data field.

**Figure 23-2. Specialized Timer Micromachine**

### 23.2.1.1 Time Slots and Resolution Loop

Each instruction requires a specific number of cycles or time slots to execute. The resolution specified in the prescaler bitfields determines the timer accuracy. All input captures, event counts, and output compares are executed once in each resolution loop. HR captures and compares are possible (up to N2HET clock accuracy) on the HR I/O pins. For more information about the HR I/O structure, see [Section 23.2.5](#).

### 23.2.1.2 Program Loop Time

The program loop time is the sum of all cycles used for instruction execution. This time may vary from one loop to another if the N2HET program includes conditionally executed instructions.

The timer program restarts on every resolution loop. The start address is fixed at N2HET RAM address 00h. The longest path through a program must fit within one loop resolution period to guarantee complete accuracy.

The last instruction of a program must branch back to the fixed start address (next program address=00h). When an N2HET program branches back to address 00h before the end of a loop resolution period, the N2HET detects this and pauses instruction execution until the beginning of the next loop resolution period.

The timing diagram below illustrates the program flow execution.

**Figure 23-3. Program Flow Timings**

### 23.2.1.3 Instruction Execution Sequence

The execution of a N2HET program begins with the first occurrence of the loop resolution clock, after the N2HET is turned on. At the first and subsequent occurrences of the loop resolution, the instruction at location address 00h is prefetched. The program execution begins at the occurrence of the loop resolution clock and continues executing the instructions until the program branches to 00h location. The instruction is prefetched at location 00h and execution flag is reset. The N2HET pauses instruction execution until the occurrence of the loop resolution clock and resumes normal execution.

N2HET programs must be written so that they complete execution and return to address 00h before the occurrence of the next loop resolution clock. If the N2HET program exceeds this execution time limit, then a program overflow condition occurs as described in [Section 23.2.1.4](#).

### 23.2.1.4 Program Overflow Condition

If the number of time slots used in a program loop exceeds the number available time slots in one loop resolution, the timer sets the program overflow interrupt flag located in the HETEXC2 register. To maintain synchronization of the I/Os, this condition should never be allowed to occur in a normal operation. The HETEXC2.PRGMOVRFLAG flag provides a mechanism for checking that the condition does not occur during the debug and validation phases.

As Figure 23-4 illustrates, when a program overflow occurs, the currently executing N2HET program sequence is interrupted and restarted at N2HETAddress 0 for the beginning of the next loop resolution clock period. Also, HETEXC2.PRGMOVRFLFLAG is set.

If the instruction that caused the overflow (instruction at address 0xC in Figure 23-4) has any pin actions selected, these pin actions will not be performed. However other actions of the instruction including register and RAM updates will still be performed.

**Figure 23-4. Use of the Overflow Interrupt Flag (HETEXC2)**

#### 23.2.1.5 Architectural Restrictions on N2HET Programs

Certain architectural restrictions apply to N2HET programs:

1. The size of an N2HET program must be greater than one instruction.
2. An extra wait state is incurred by any instruction that modifies a field in the next instruction to be executed.
3. Only one instruction (using high resolution) is allowed per high resolution pin.
4. Consecutive break points are not supported. Instructions with break points must have at least a distance of two instructions (for example, at addresses 1, 3, 5, 7, and so on, assuming the program executes linearly)

**NOTE:** While it would be unusual to code an N2HET program that is only one instruction long, it is trivial to modify such a program to meet the requirement of restriction 1. Simply add a second instruction to the program, which may be a simple branch to zero.

To enforce restriction 3, the high resolution pin structures respond only to the first instruction that is executed matching their pin number with `hr_lr=HIGH`, regardless of whether or not the `en_pin_action` field is ON. Subsequent instructions are ignored by the high resolution pin structure for the remainder of the loop resolution period.

#### 23.2.1.6 Multi-Resolution Scheme

The N2HET has the capability to virtually extend the counter width by executing instructions only once every N loop resolution periods. This decreases the timer resolution, but extends the counter range which may be useful when generating or measuring slow signals. Figure 23-5 illustrates how a multi-resolution scheme may be implemented in an N2HET program. An unconditional Branch instruction and an index sequence, using a MOV64 instruction in each low resolution loop, is required to control this particular program flow.

**NOTE:** HR instructions must be placed in the main (full resolution) loop to ensure proper operation.

**Figure 23-5. Multi-Resolution Operation Flow Example**

### 23.2.1.7 Debug Capability

The N2HET supports breakpoints to allow you to more easily debug your N2HET program. [Figure 23-6](#) provides an illustration of the breakpoint mechanism.

The steps to enable an N2HET breakpoint are:

1. Make sure the device nTRST pin is high, since N2HET breakpoints are disabled whenever this pin is low. (Normally this is handled automatically when a JTAG debugger is attached).
2. Attach a JTAG debugger and connect to the device that has been already programmed with the N2HET code that needs to be debugged. (downloading to on-chip flash is outside the scope of this section).
3. Execute the CPU program at least until the point where the N2HET program RAM has been initialized by the CPU.
4. Open a memory window in the N2HET registers.
5. Make sure NHETEXC2.DEBUGSTATUSFLAG is cleared.
6. Open a memory window on the N2HET RAM
7. Set bit 22 in the program field of the instruction(s) on which you wish to break. Note that this instruction will be executed **before** the N2HET is halted - slightly different from how CPU breakpoints behave.
8. Make sure the CPU and N2HET are running, if they are halted then restart the CPU through the JTAG emulator (N2HET will start when the CPU starts).
9. Both the CPU and N2HET will halt when breakpoint is reached.

When the N2HET is halted, its state machines are frozen but all of the N2HET control registers can be accessed through the JTAG emulator interface.

The current N2HET instruction address can be inspected by reading the HETADDR register; this should be pointing to the instruction that caused the breakpoint.

The N2HET internal working registers (A,B,R,S,T) are not directly visible through the JTAG emulator interface. If the content of these registers needs to be inspected, it is best to add an instruction like MOV32 which copies the register value to the N2HET RAM. This RAM location can be inspected when the N2HET halts.

To restart execution of both the CPU and the N2HET from the halted state:

1. Clear NHETEXC2.DEBUGSTATUSFLAG.
2. Clear bit 22 in the program field of the instruction on which the breakpoint was reached.
3. Restart the CPU through the normal JTAG emulator procedure ('Run' or 'Go'). The N2HET will automatically start executing when it sees that the CPU has exited the debug state.

**Figure 23-6. Debug Control Configuration**

**NOTE:** Consecutive break points are not supported. Instructions with break points must have at least a distance of two instructions (for example, at N2HET addresses 1, 3, 5, 7, and so on)

### 23.2.2 N2HET RAM Organization

The N2HET RAM is organized into two sections. The first contains the N2HET program itself. The second contains parity protection bits for the N2HET program.

Each N2HET instruction is 96-bits wide but aligned to a 128-bit boundary. Instructions consist of three 32-bit fields: Program, Control, and Data. Instructions are separated by a fourth unimplemented address to force alignment to 128-bit boundaries.

The integrity of the N2HET program can be protected by Parity. Parity protection is enabled through the N2HET Parity Control Register (HETPCR).

Table 23-1 shows the base addresses for N2HET RAM and N2HET Parity RAM.

**Table 23-1. N2HET RAM Base Addresses**

| N2HET1 Base Address | N2HET2 Base Address | Memory                                       |
|---------------------|---------------------|----------------------------------------------|
| 0xFF46_0000         | 0xFF44_0000         | N2HET Instruction RAM (Program/Control/Data) |
| 0xFF46_2000         | 0xFF44_2000         | N2HET Parity RAM                             |

### 23.2.2.1 N2HET RAM Banking

Because the CPU must make updates to the N2HET RAM while the N2HET is executing, for example to update the duty cycle value of a PWM, it is important to understand how the N2HET RAM organization facilitates simultaneous accesses by both the HOST CPU and the N2HET.

The N2HET RAM is implemented as 4 banks of 96-bit wide two port RAM. This means that there a total of 8 ports available; four read and four write. Normally the N2HET will use up to two of these ports at a time. One read port is used to allow the N2HET to prefetch the next N2HET instruction while a write port may be used to update the data or control fields that have changed as a result of executing the current instruction.

N2HET accesses to its own internal RAM are given priority over accesses from an external host (CPU or DMA), this makes N2HET program execution deterministic which is a critical requirement for a timer.

Most N2HET instructions execute in a single cycle. Cases where a wait state impacts the N2HET program execution time are:

- The current N2HET instruction writes data back to the next N2HET in the execution sequence.
- The external host reads from an N2HET instruction where the automatic read-clear option is set, while the N2HET is executing from/on the same address (See [Section 23.2.4.3](#)).

Except for the case of automatic read-clear, the external host is stalled when the host and N2HET have a bank conflict. However this will typically only result in a stall of one cycle, due to the N2HET bank ordering which is organized on the N2HET Address least significant bit boundaries (See [Table 23-2](#)).

Assuming most of the N2HET program executes linearly through the N2HET Address space; if a bank conflict does exist it is usually resolved in the next cycle as the N2HET program moves to the next bank. N2HET programmers should avoid writing a program that accesses the same bank of N2HET RAM on every cycle, as this could lock the external host out of the N2HET memory completely.

[Table 23-2](#) describes the N2HET memory map, as viewed by the N2HET as well as from the memory space of the host CPU and DMA.

**Table 23-2. N2HET RAM Bank Structure**

| N2HET Address | Host CPU or DMA Address Space |                       |                    |                  | N2HET RAM Bank |
|---------------|-------------------------------|-----------------------|--------------------|------------------|----------------|
|               | Program Field Address         | Control Field Address | Data Field Address | Reserved Address |                |
| 000h          | XX0000h                       | XX0004h               | XX0008h            | XX000Ch          | A              |
| 001h          | XX0010h                       | XX0014h               | XX0018h            | XX001Ch          | B              |
| 002h          | XX0020h                       | XX0024h               | XX0028h            | XX002Ch          | C              |
| 003h          | XX0030h                       | XX0034h               | XX0038h            | XX003Ch          | D              |
| 004h          | XX0040h                       | XX0044h               | XX0048h            | XX004Ch          | A              |
| :             | :                             | :                     | :                  | :                | :              |
| 03Fh          | XX03F0h                       | XX03F4h               | XX03F8h            | XX03FCh          | D              |
| 040h          | XX0400h                       | XX0404h               | XX0408h            | XX040Ch          | A              |
| :             | :                             | :                     | :                  | :                | :              |
| 1FFh          | XX1FF0h                       | XX1FF4h               | XX1FF8h            | XX1FFCh          | D              |

**NOTE:** The external host interface supports any access size for reads, but only 32-bit writes to the N2HET RAM are supported. Reserved addresses should not be accessed, the result of doing so is indeterminate.

### 23.2.2.2 Parity Checking

The N2HET module can detect parity errors in N2HET RAM. As described in [Section 23.2.2](#) the N2HET allows 32-bit writes only. Therefore N2HET RAM parity checking is implemented using one parity bit per 32-bit field in N2HET RAM.

Even or odd parity selection for N2HET parity detection can be configured in the system module. Parity calculation and checking can be enabled/disabled by a 4-bit key in HETPCR.

During a read access to the N2HET RAM, the parity is calculated based on the data read from the RAM and compared with the good parity value stored in the parity bits. The parity check is performed when the N2HET execution unit makes a read access to N2HET RAM, but also when a different master (for example, CPU, HTU, DMA) performs the read access. If any 32-bit-word fails the parity check then an error is signaled to the ESM module. The N2HET address, which generated the error is detected and is captured in HETPAR for host system debugging. The address is frozen from being updated until it is read by the bus master.

The N2HET execution unit reads the instructions, which are 96-bit wide. They contain the program-, control- and data-field whereby each is 32-bit wide. So when fetching N2HET instructions parity checking is performed on three words in parallel.

If a parity error is detected in two or more words in the same cycle then only one address (word at the lower address) is captured. The captured N2HET address is always aligned to a 32-bit word boundary.

During debug, parity checking is still performed on accesses originating from the on-chip host CPU and DMA. However, parity errors that are detected during an access initiated by the debugger itself are ignored.

### 23.2.2.3 Parity Error Detection Actions

Detection of a N2HET parity error causes the following actions:

1. An error is signaled to the ESM module.
2. The Parity Address Register (HETPAR) is loaded with the address of the faulty N2HET field.
3. N2HET execution immediately stops. (The instruction that triggered the parity error is not executed.)
4. The Turn-On/Off-Bit in the N2HET Global Configuration Register (HETGCR) is automatically cleared.
5. All N2HET internal flags are cleared.
6. All N2HET pins selected by N2HET Parity Pin Register (HETPPR) enter a predefined safe state.
7. Register HETDOUT is also updated to reflect changes in pin state due to HETPPR.

The safe state for N2HET pins selected through the HETPPR register depends on how the pin is configured in the HETDIR, HETPDR, and HETPSL registers. [Table 23-3](#) explains how the safe state is determined.

**Table 23-3. Pin Safe State Upon Parity Error Detection**

| Safe State     | HETDIR | HETPDR | HETPSL |
|----------------|--------|--------|--------|
| Drive Low      | 1      | 0      | 0      |
| Drive High     | 1      | 0      | 1      |
| High Impedance | 1      | 1      | x      |

### 23.2.2.4 Testing Parity Detection Logic

To test the parity detection logic, the parity RAM has to be made accessible to the CPU in order to allow a diagnostic program to insert parity errors. The control register bit HETPCR.TEST must be set in order to make the parity RAM accessible. Once HETPCR.TEST is set, the parity bits are accessible as described in [Table 23-4](#).

**Table 23-4. N2HET Parity Bit Mapping**

| Address<br>N2HET1 | Address<br>N2HET2 | Bits                           |                                        |
|-------------------|-------------------|--------------------------------|----------------------------------------|
|                   |                   | [31:1]                         | [0]                                    |
| 0xFF46_2000       | 0xFF44_2000       | Reads 0, Writes have no effect | Instruction 0 Program Field Parity Bit |
| 0xFF46_2004       | 0xFF44_2004       | Reads 0, Writes have no effect | Instruction 0 Control Field Parity Bit |
| 0xFF46_2008       | 0xFF44_2008       | Reads 0, Writes have no effect | Instruction 0 Data Field Parity Bit    |
| 0xFF46_200C       | 0xFF44_200C       | Reads 0, Writes have no effect | Read 0                                 |

**Table 23-4. N2HET Parity Bit Mapping (continued)**

| Address<br>N2HET1 | Address<br>N2HET2 | Bits                           |                                        |
|-------------------|-------------------|--------------------------------|----------------------------------------|
|                   |                   | [31:1]                         | [0]                                    |
| 0xFF46_2010       | 0xFF44_2010       | Reads 0, Writes have no effect | Instruction 1 Program Field Parity Bit |
| ....              | ....              | ...                            | ...                                    |

Each 32-bit N2HET field has its own parity bit in the N2HET Parity RAM as shown in [Table 23-4](#). There are no parity bits for the reserved fields, since there is no physical N2HET RAM for these fields.

### 23.2.2.5 Initialization of Parity RAM

After device power up, the N2HET RAM contents including the parity bits cannot be guaranteed. In order to avoid false parity failures due to the random state in which RAM powers up, the RAM has to be initialized.

Before initializing the N2HET RAM, enable the N2HET parity logic by writing to HETPCR. Then the N2HET Instruction RAM should be initialized. With parity enabled, the N2HET parity RAM will be initialized automatically by N2HET at the same time that the N2HET instruction RAM is initialized by the CPU. Note that loading the N2HET program with parity enabled is also effective.

Another possibility to initialize the N2HET memory and its parity bits is, to use the system module to start the automatic initialization of all RAMs on the microcontroller. The RAMs will be initialized to '0'. Depending on the even/odd parity selection, the parity bit will be calculated accordingly.

### 23.2.3 Time Base

All N2HET timings are derived from VCLK2 (see [Figure 23-7](#)). Internally N2HET instructions execute at the VCLK2 rate; but the timer loop clock and the high-resolution hardware timer clock can be scaled down from VCLK2. Two prescalers are available to adjust the timer loop resolution clock for the program loop, and the high resolution (HR) clock for the HR I/O counters.

- **Time Slots:** The number of cycles available for instruction execution per loop. Time Slots is the number of VCLK2 cycles in a Loop Resolution Clock.
- **High Resolution Clock:** The high resolution clock is the smallest time increment with which a pin can change it's state or can be measured in the case of input signals. A 6-bit prescaler dividing VCLK2 by a user-defined HR prescale divide rate (hr) stored in the 6-bit HR prescale factor code (HETPFR). See [Table 23-5](#).
- **Loop Resolution Clock:** The loop resolution clock defines the timebase for executing all instructions in a N2HET program. Since instructions can be conditionally executed, the longest path through the N2HET program must fit into one loop resolution clock period (LRP). A 3-bit prescaler dividing the HR clock by a user-defined loop-resolution prescale divide rate (lr) stored in the 3-bit loop-resolution prescale factor code (HETPFR). See [Table 23-5](#).

**Figure 23-7. Prescaler Configuration**

The following abbreviations and relations are used in this document:

1. hr: high resolution prescale factor (1, 2, 3, 4,..., 63, 64)
2. lr: loop resolution prescale factor (1, 2, 4, 8, 16, 32, 64,128)
3. ts: Time slots (cycles) available for instruction execution per loop.  $ts = hr \times lr$
4. HRP = high resolution clock period  $HRP = hr \cdot T_{VCLK2} \text{ (ns)}$
5. LRP = loop resolution clock period  $LRP = lr \cdot HRP \text{ (ns)}$

The loop resolution period (LRP) must be selected to be larger than the number of Time slots (VCLK2 cycles) required to complete the worst-case execution path through the N2HET program. Otherwise a program overflow condition may occur (see [Section 23.2.1.4](#)). Because of the relationship of time slots to the hr and lr prescalers as described in item 3 above, increasing either hr or lr increases the number of time slots available for program execution. However, lr would typically be increased first, since increasing hr results in a decrease in timer resolution since it reduces the clock to the High Resolution IO structures.

The divide rates hr and lr can be defined in the HETPFR register. [Table 23-5](#) lists the bit field encodings for the prescale options.

**Table 23-5. Prescale Factor Register Encoding**

| LRPFC - Loop Resolution |                    | HRPFC - High Resolution |                    |
|-------------------------|--------------------|-------------------------|--------------------|
| HETPFR[10:8]            | Prescale Factor lr | HETPFR[5:0]             | Prescale Factor hr |
| 000                     | /1                 | 000000                  | /1                 |
| 001                     | /2                 | 000001                  | /2                 |
| 010                     | /4                 | 000010                  | /3                 |
| 011                     | /8                 | 000011                  | /4                 |
| 100                     | /16                | .....                   | :                  |
| 101                     | /32                | 111101                  | /62                |
| 110                     | /64                | 111110                  | /63                |
| 111                     | /128               | 111111                  | /64                |

### 23.2.3.1 Determining Loop Resolution

As an example, consider an application that requires high resolution of HRP = 62.5 ns, and loop resolution of LRP = 8 µs, and needs at least 250 time slots for the N2HET application program.

Assuming VCLK2 = 32 MHz, the following shows which divide-by rates and which value in the Prescale Factor Register (HETPFR) is required for the above requirements:

$$hr = 2 \rightarrow HRP = \frac{hr}{VCLK2} = \frac{2}{32MHz} = 62.5ns$$

$$lr = 128 \rightarrow lr \times HRP = 128 \times 62.5ns = 8 \mu s$$

$$ts = hr \times lr = 2 \times 128 = 256$$

$$hr = 2, lr = 128 \rightarrow HETPFR[31:0] = 0x00000701 \quad (34)$$

In the example above, if the loop resolution period needs to decrease from 8 µs to 4 µs, then only 128 time slots will be available for program execution. The program may need to be restructured as suggested in [Section 23.2.1.6](#), *Multi-Resolution Scheme*.

### 23.2.3.2 The 7-Bit HR Data Field

The instruction execution examples of ECMP ([Section 23.2.5.9](#)), MCMP ([Section 23.2.5.10](#)), PCNT ([Section 23.2.5.12](#)), PWCNT ([Section 23.2.5.11](#)), and WCAP ([Section 23.2.5.13](#)) show that the 7-bit HR data field can generate or measure high resolution delays (HR delay) relative to the start of an LRP within one N2HET loop LRP. The last section showed that:

$$LRP = lr \times HRP$$

There are lr high resolution clock periods (HRP) within the N2HET loop resolution clock period (LRP). If lr = 128 then the HR delay can range from 0 to 127 HRP clocks within LRP and all 7 bits of the HR data field are needed. Instead of being limited to measuring and triggering events based on the loop resolution clock period (LRP) the HR extension allows measurements and events to be described in terms fractions of an LRP (down to 1/128 of an LRP). The only limitation is that a maximum of one HR delay can be specified per pin during each loop resolution period.

Table 23-6 shows which bits of the HR data field are not used by the high resolution IO structures if  $I_r$  is less than 128. In this case the non-relevant bits (LSBs) of the HR data fields will be one of the following:

- Written as 0 for HR capture (for PCNT, WCAP)
- Or interpreted as 0 for HR compare (for ECMP, MCMP, PWCNT)

**Table 23-6. Interpretation of the 7-Bit HR Data Field**

| Loop Resolution<br>Prescale divide rate ( $I_r$ ) | Bits of the HR data field <sup>(1)</sup> |             |           |         |       |      |       | HRP Cycles delay range |
|---------------------------------------------------|------------------------------------------|-------------|-----------|---------|-------|------|-------|------------------------|
|                                                   | D[6]                                     | D[5]        | D[4]      | D[3]    | D[2]  | D[1] | D[0]  |                        |
| 1                                                 | X X X X X X X                            |             |           |         |       |      |       | 0                      |
| 2                                                 | 1/2                                      | X X X X X X |           |         |       |      |       | 0 to 1                 |
| 4                                                 | 1/2                                      | 1/4         | X X X X X |         |       |      |       | 0 to 3                 |
| 8                                                 | 1/2                                      | 1/4         | 1/8       | X X X X |       |      |       | 0 to 7                 |
| 16                                                | 1/2                                      | 1/4         | 1/8       | 1/16    | X X X |      |       | 0 to 15                |
| 32                                                | 1/2                                      | 1/4         | 1/8       | 1/16    | 1/32  | X X  |       | 0 to 31                |
| 64                                                | 1/2                                      | 1/4         | 1/8       | 1/16    | 1/32  | 1/64 | X     | 0 to 63                |
| 128                                               | 1/2                                      | 1/4         | 1/8       | 1/16    | 1/32  | 1/64 | 1/128 | 0 to 127               |

<sup>(1)</sup> X = Non-relevant bit (treated as '0')

#### 23.2.3.2.1 Example:

Prescale Factor Register (HETPFR) = 0x0300

→  $I_r = 8$  → LRP =  $8 \cdot \text{HRP}$

Assumption: HR data field = 0x50 = 1010000b

$I_r = 8$  → Bits D[3:0] are ignored → HR delay = 101b = 5 HRP

or by using the calculation with weight factors:

HR Delay

$$\begin{aligned}
 &= I_r \cdot (D[6] \cdot 1/2 + D[5] \cdot 1/4 + D[4] \cdot 1/8 + D[3] \cdot 1/16 + D[2] \cdot 1/32 + D[1] \cdot 1/64 + D[0] \cdot 1/128) \\
 &= 8 \cdot (1 \cdot 1/2 + 0 \cdot 1/4 + 1 \cdot 1/8 + 0 \cdot 1/16 + 0 \cdot 1/32 + 0 \cdot 1/64 + 0 \cdot 1/128) \\
 &= 5 \text{ HRP}
 \end{aligned}$$

### 23.2.4 Host Interface

The host interface controls all communications between timer-RAM and masters accessing the N2HET RAM. It includes following components:

#### 23.2.4.1 Host Accesses to N2HET RAM

The host interface supports the following types of accesses to N2HET RAM:

- Read accesses of 8, 16, or 32 bits
- Read accesses of 64-bits that follow the shadow register sequence described in [Section 23.2.4.2](#).
- Write accesses of 32 bits

Writes of 8 or 16 bits to N2HET RAM by an external host are not supported.

#### 23.2.4.2 64-bit Read Access

The consecutive read of a control field CF(n) and a data field DF(n) of the same instruction (n) performed by the same master (for example, CPU, DMA, or any other master) is always done as a simultaneous 64-bit read access. This means that at the same time CF(n) is read, DF(n) is loaded in a shadow register. So the second access will read DF(n) from the shadow register instead of the N2HET RAM.

In general a 64-bit read access of one master could be interrupted by a 64-bit read access of another master. A total of three shadow registers are available. Therefore up to three masters can perform 64-bit reads in an interleaved manner (Master1 CF, Master2 CF, Master3 CF, Master1 DF, Master2 DF, Master3 DF).

If all three shadow registers are activated and a 4th master performs a CF or DF read it will result in an address error and the RAM access will not happen. Other access types by a fourth master (reads from the PF field or writes to any of the fields) will occur because these access types do not require an available shadow register resource to complete.

#### 23.2.4.3 Automatic Read Clear Feature

The N2HET provides a feature allowing to automatically clear the data field immediately after the data field is read by the external host CPU (or DMA). This feature is implemented via the *control bit*, which is located in the control field (bit C26). This is a static bit that can be used by any instruction, and specified in the N2HET program by adding the option (control = ON) to the N2HET instruction. The automatic read clear feature works for both 32 and 64 bit reads that follow the sequence described in [Section 23.2.4.2](#).

When the host CPU reads the data field of that instruction, the current data value is returned to the host CPU but the field is cleared automatically as a side effect of the read. In case the master reads data from an instruction currently executing, any new capture result is stored and this takes priority over the automatic read clear feature, so that the new capture result is not lost.

As an example of where the automatic read clear feature is useful, consider the PCNT instruction. If this instruction is configured for automatic read clear, then when the host CPU reads the PCNT data field it will be cleared automatically. The host CPU can then poll the PCNT data field again, and as long as the field returns a value of zero the host CPU program knows a new capture event has not occurred. If the data field were not cleared, it would be impossible for the host CPU to determine whether the data field holds data from the previous capture event, or if it happens to be data from a new capture event with the same value.

#### 23.2.4.4 Emulation Mode

Emulation mode, used by the software debugger, is specified in the global configuration register. When the host CPU debugger hits a breakpoint, the CPU sends a suspend signal to the modules. Two modes of operation are provided: suspend and ignore suspend.

- Suspend

When a suspend is issued, the timer operation stops at the end of the current timer instruction. However, the CPU accesses to the timer RAM or control registers are freely executed.

- Ignore suspend

The timer RAM ignores the suspend signal and operates real time as normal.

#### 23.2.4.5 Power-Down

After setting the turn-off bit in the Global Configuration Register (HETGCR), it is required to delay until the end of the timer program loop before putting the N2HET in power-down mode. This can be done by waiting until the N2HET Current Address (HETADDR) becomes zero, before disabling the N2HET clock source in the device's Global Clock Module (GCM).

### 23.2.5 I/O Control

The N2HET has up to 32 pins. Refer to device specific data sheets for information concerning the number of N2HETIO available. All of the N2HET pins available are programmable as either inputs or outputs.

These 32 I/Os have an identical structure connected to pins HET[31] to HET[0]. See [Figure 23-8](#) for an illustration of the I/O control. In addition all 32 I/Os have a special HR structure based on the HR clock. This structure allows any N2HET instruction to use any of these I/Os with an accuracy of either loop resolution or high resolution accuracy.

**Figure 23-8. I/O Control**

Pins N2HET [31] to N2HET [0] can be used by the CPU as general purpose inputs or outputs using the N2HET Data Input Register (HETDIN) for reading and N2HET Data Output Register (HETDOUT), N2HET Data Set Register (HETDSET) or N2HET Data Clear Register (HETDCLR) for writing, depending on the type of action to perform. The N2HET pins used as general purpose inputs are sampled on each VCLK2 period.

### 23.2.5.1 Using General Purpose I/O Data Set and Clear Registers

The N2HET Data Clear Register (HETDCLR) and N2HET Data Set Register (HETDSET) can be used to minimize the number of accesses to the peripheral to modify the output register and output pins. When the application needs to set or to reset some N2HET pins without changing the value of the others pins, the first possibility is to read N2HET Data Output Register (HETDOUT), modify the content (AND, OR, etc.), and write the result into N2HET Data Output Register (HETDOUT). However, this read-modify-write sequence could be interrupted by a different function modifying the same register which will result in a data coherency problem.

Using the N2HET Data Set Register (HETDSET) or N2HET Data Clear Register (HETDCLR), the application program must write the mask value (same mask value for the first option) to the register to set or reset the desired pins. Any bits written as 0 to HETDSET and HETDCLR are left unchanged, which avoids the possible coherency problem of the read-modify-write approach.

Coding Example (C program): Set pins using the 2 methods.

```
unsigned int MASK;                                /* Variable that content the bit mask */
volatile unsigned int *HETDOUT,*HETDSET;          /* Pointer to HET registers */
...
*HETDOUT = *HETDOUT | MASK;                       /* Read-modify-write of HETDOUT */
*HETDSET = MASK;                                   /* Set the pin without reading HETDOUT */
```

### 23.2.5.2 Loop Resolution Structure

The N2HET uses the pins N2HET [31:0] as input and/or output by the way of the instruction set. Actually, each pin could monitor the N2HET program or could be monitored by the N2HET program. By using the I/O register of the N2HET, the CPU is able to interact with the N2HET program flow.

When an action (set or reset) is taken on a pin by the N2HET program, the N2HET will modify the pin at the rising edge of the next loop resolution clock.

When an event occurs on a N2HET I/O pin, it is taken into account at the next rising edge of the loop resolution clock.

The structure of each pin is shown in [Figure 23-9](#).

Figure 23-9. N2HET Loop Resolution Structure for Each Bit

The example in Figure 23-10 shows a simple PWM generation with loop resolution accuracy. The corresponding program is:

HETPFR[31:0] register = 0x201 --> lr=4 and hr=2 --> ts = 8

**N2HET Program:**

```
L00 CNT { next= L01, reg=A, irq=OFF, max = 4 }
L01 ECMP { next= L00, cond_addr= L00, hr_lr=LOW, en_pin_action=ON, pin=0,
          action=PULSEHI, reg=A, irq=OFF, data= 1, hr_data = 0x0 }
```

; 25 bit compare value is 1 and the 7-bit HR compare value is 0

The CNT and ECMP instructions are executed once each loop resolution cycle. When the CNT instruction is executed, the specified register (A) and the CNT instruction data field are both incremented by one. Next the ECMP is executed and the data field of the ECMP is compared with the specified register (A). If both values match, then the pin action (PULSEHI in this case) will be performed in the next loop resolution cycle. The CNT continues incrementing each loop resolution cycle. When the data field overflows (max + 1), then the Z-flag is set by the CNT instruction. In the next loop resolution cycle, the Z-flag is evaluated and the opposite pin action is performed if it is set. The Z-flag will only be active for one loop resolution cycle.

Figure 23-10. Loop Resolution Instruction Execution Example

### 23.2.5.3 High Resolution Structure

All 32 I/Os provide the HR structure based on the HR clock. The HR clock frequency is programmed through the Prescale Factor Register (HETPFR). In addition to the standard I/O structure, all pins have HR hardware so that these pins can be used as HR input captures (using the HR instructions PCNT or WCAP) or HR output compares (using the HR instructions ECMP, MCMP or PWCNT).

All five HR instructions (PCNT, WCAP, ECMP, MCMP and PWCNT) have a dedicated `hr_lr` bit (high resolution/low resolution; program field bit 8) allowing operation either in HR mode or in standard resolution mode by ignoring the HR field. By default, the `hr_lr` bit value is 0 which implies HR operation mode. However, setting this bit to one allows the use of several HR instructions on a single HR pin. Only one instruction is allowed to operate in HR mode (bit cleared to 0), but the other instructions can be used in standard resolution mode (bit set to 1).

### 23.2.5.4 HR Block Diagram

Each time an HR instruction is executed on a given pin, the HR structure for that pin is programmed (which HR function to perform and on which edges it should take an action) with the information given by the instruction. The HR structure for each pin decodes the pin select field of the instruction and programs its HR structure if it matches.

**NOTE:** For each N2HET pin, only one instruction specifying a high resolution operation (`hr_lr=HIGH`) is allowed to execute per loop resolution period. This includes any instructions where (`hr_lr=HIGH`) but (`en_pin_action=OFF`).

The first high resolution instruction that executes and specifies a particular pin locks out subsequent high resolution instructions from operating on the same pin until the end of the current loop resolution period.

**Figure 23-11. HR I/O Architecture**

### 23.2.5.5 HR Structures Sharing (Input)

The HR Share Control Register (HETHRSH) allows two HR structures to share the same pin **for input capture only**. If these bits are set, the HR structures N and N+1 are connected to pin N. In this structure, pin N+1 remains available for general purpose input/output. See [Figure 23-12](#).

**Figure 23-12. Example of HR Structure Sharing for N2HET Pins 0/1**

The following program gives an example how the HR share feature (HET[0] HR structure and HET[1] HR structure shared) can be used for the PCNT instruction:

```
L00 PCNT { next=L01, type=rise2fall, pin=0 }
L01 PCNT { next=L00, type=fall2rise, pin=1 }
```

The HET[1] HR structure is also connected to the HET[0] pin. The L00\_PCNT data field is able to capture a high pulse and the L01\_PCNT captures a low pulse on the **same** pin (N2HET [0] pin).

### 23.2.5.6 AND / XOR-shared HR Structure (Output)

Usually the N2HET design allows only one HR structure to generate HR edges on a pin configured as output pin. The HETXOR register allows a logical XOR of the output signals of two consecutive HR structures N (even) and N+1 (odd). See [Figure 23-13](#). In this way, it is possible to generate pulses smaller than the loop resolution clock since both edges can be generated by two independent HR structures. This is especially required for symmetrical PWM. See [Figure 23-14](#).

The hardware provides a XOR gate that is connected to the outputs of the HR structure of two consecutive pins. In this structure, pin N+1 remains available for general purpose input/output.

**Figure 23-13. XOR-shared HR I/O**

The following N2HET program gives an example for **one** channel of the symmetrical PWM. The generated timing is given in [Figure 23-14](#).

```
MAXC .equ 22
A_ .equ 0 ; HR structure HR0
B_ .equ 1 ; HR structure HR1

CN CNT { next=EA, reg=A, max=MAXC }

EA ECMP { next=EB, cond_addr=MA, hr_lr=HIGH, en_pin_action=ON, pin=A_,
          action=PULSE0, reg=A, data=17, hr_data=115 }

MA MOV32 { next=EB, remote=EA, type=IMTOREG&REM, reg=NONE, data=17, hr_data=19 }

EB ECMP { next=CN, cond_addr=MB, hr_lr=HIGH, en_pin_action=ON, pin=B_,
          action=PULSE0, reg=A, data=5, hr_data=13 }

MB MOV32 { next=CN, remote=EB, type=IMTOREG&REM, reg=NONE, data=5, hr_data=13 }
```

N2HET Settings and output signal calculation for this example program:

- Pin HET[0] and HET[1] are XOR-shared.
- HETPFR[31:0] register = 0x700: lr=128, hr=1, time slots ts = 128
- PWM period (determined by CNT\_max field) = (22+1) · LRP = 2944 HRP
- Length of high pulse of (HET[0] XOR HET[1]) =  
 $LH = (17 \cdot LRP + 115 \cdot HRP) - (5 \cdot LRP + 13 \cdot HRP)$   
 With lr=128 there is LRP = 128 · HRP, so  
 $LH = (2291 - 653) \cdot HRP = 1638 \text{ HRP}$
- Duty cycle = DC = LH / PWM\_period = 1638 HRP / (2944 · HRP) = 55.6 %

[Figure 23-14](#) graphically shows the implementation of the XOR-shared feature. The first 2 waveforms (symmetrical counter and CNT) show a symmetric counter and asymmetric counter. The symmetric counter is shown only to highlight the axis of symmetry and is not implemented in the N2HET. The asymmetric counter, which is implemented with a CNT instruction, needs to be set to the period of the symmetric counter. The next two waveforms (HR [0] and HR [1]) show the output of the HR structures, which are the inputs for the XOR gate to create the PWM output on pin HET[0]. Notice that the pulses of signal HET[0] are centered about the axis of symmetry.

**Figure 23-14. Symmetrical PWM with XOR-sharing Output**

As an alternative, HR structures may be shared using a logical AND function to combine the effects of the pin structures. The HETAND allows sharing two consecutive HR structures N (even) and N+1 (odd). See [Figure 23-15](#). In this structure, pin N+1 remains available for general purpose input/output.

**NOTE:** Setting both the HETAND bit and HETXOR bits at the same time for a given pair of N2HET pins is not supported, must be avoided by the application program.

Figure 23-15. AND-shared HR I/O

### 23.2.5.7 Loop Back Mode

The loop back feature can be used by the application to monitor an N2HET output signal. For example, if a PWM is generated by HR structure 0, then a PCNT instruction assigned to HR structure 1 can measure back the pulse length or periods of the PWM output signal.

Loopback mode is activated between two high resolution structures by setting LBPSEL[x] to '1' in the HETLBPSEL Register for the corresponding structure pair. The **direction** of the loopback between the two structures in the structure pair is determined by the value of LBPDIR[x] in the HETLBPDIR Register.

For example, if bit LBPSEL[0] is set to '1', then HR structures 0 and 1 will be internally connected in loop back mode. If bit LBPDIR[0] is set to '0' then structure 0 will be the input and structure 1 will be the output.

#### Digital Loopback

Digital loopback mode is enabled by setting LBPTYPE[x] to '0' in the HETLBPSEL Register for the corresponding structure pairs. In digital loopback mode, the structure pairs are connected directly and the output buffers are bypassed. Therefore, the loopback values will NOT be seen on the corresponding pins. [Figure 23-16](#) below shows an example of digital loopback between structures HR0 and HR1. LBSEL[0] has been set to '1' to enable loopback between the two structures. LBTYPE[0] has been set to '0' to select digital mode for the loopback pair. The LBPDIR[0] value will determine the direction of the loopback by selecting which of the HR blocks is output, and which is input. The bold lines show the digital loopback path.

**Figure 23-16. HR0 to HR1 Digital Loopback Logic: LBTYPE[0] = '0'**

### Analog Loopback

Analog loopback mode is enabled by setting LBTYPE[x] to '1' in the HETLBPSEL Register for the corresponding structure pairs. In analog loopback mode, the structure pairs are connected outside of the output buffers. Therefore, the loopback values **WILL** be seen on the corresponding pins. [Figure 23-17](#) below shows an example of analog loopback between structures HR0 and HR1. LBSEL[0] has been set to '1' to enable loopback between the two structures. LBTYPE[0] has been set to '1' to select analog mode for the loopback pair. The LPBDIR[0] value will determine the direction of the loopback by selecting which of the HR blocks is output, and which is input. The bold lines show the analog loopback path.

**Figure 23-17. HR0 to HR1 Analog Loop Back Logic: LBTYPE[0] = '1'**

Note:

- The loop back direction can be selected independent of the HETDIR register setting.
- The pin which is not driven by the N2HET output pin actions can still be used as normal GIO pin.

#### 23.2.5.8 Edge Detection Input Timing

There are several timing requirements for input signals in order to be captured correctly by N2HET. [Figure 23-18](#) illustrates these requirements, with min and max values described in [Table 23-7](#) (Loop Resolution) and [Table 23-8](#) (High Resolution).

**Figure 23-18. N2HET Input Edge Detection**

**Table 23-7. Edge Detection Input Timing for Loop Resolution Instructions**

| Parameter # | Description                                       | min                                 | max                                               |
|-------------|---------------------------------------------------|-------------------------------------|---------------------------------------------------|
| 1           | Input Signal Period, rising edge to rising edge   | > 2 (hr) (lr) t <sub>c(VCLK2)</sub> | < 2 <sup>25</sup> (hr) (lr) t <sub>c(VCLK2)</sub> |
| 2           | Input Signal Period, falling edge to falling edge |                                     |                                                   |
| 3           | Input Signal, high phase                          | > (hr) (lr) t <sub>c(VCLK2)</sub>   |                                                   |
| 4           | Input Signal, high phase                          |                                     |                                                   |

**Table 23-8. Edge Detection Input Timing for High Resolution Instructions**

| Parameter # | Description                                       | min                               | max                                               |
|-------------|---------------------------------------------------|-----------------------------------|---------------------------------------------------|
| 1           | Input Signal Period, rising edge to rising edge   | > (hr) (lr) t <sub>c(VCLK2)</sub> | < 2 <sup>25</sup> (hr) (lr) t <sub>c(VCLK2)</sub> |
| 2           | Input Signal Period, falling edge to falling edge |                                   |                                                   |
| 3           | Input Signal, high phase                          | > 2 (hr) t <sub>c(VCLK2)</sub>    |                                                   |
| 4           | Input Signal, high phase                          |                                   |                                                   |

These are the N2HET architectural limitations. Actual limitations will be slightly different due to on chip routing and IO buffer delays, usually by several nanoseconds. Be sure to consult the device datasheet for actual timings that apply to that device. Also, certain devices place additional restrictions on which pins support the high resolution timings of [Table 23-8](#), if present these additional limitations will also be called out in the device datasheet.

Note that the max limit in [Table 23-7](#) and [Table 23-8](#) is based on the counter range of a single N2HET instruction. The max value could be extended by employing an additional N2HET instruction to keep track of counter overflows of the input counter / capture instruction.

### 23.2.5.9 PWM Generation Example 1 (in HR Mode)

The following example shows how an ECMP instruction works in high resolution mode. The example assumes a VCLK2 of 32 MHz and the following values for the prescale divide rates (hr and lr), number of time slots (ts), high and loop resolution period (HRP and LRP):

$$\text{hr} = 2, \text{lr} = 4, \text{ts} = \text{hr} \cdot \text{lr} = 8$$

$$\text{HRP} = \text{hr} / \text{VCLK2} = 2 / 32 \text{ MHz} = 62.5 \text{ ns}$$

$$\text{LRP} = (\text{hr} \cdot \text{lr}) / \text{VCLK2} = 8 / 32 \text{ MHz} = 250 \text{ ns}$$

With ts=8 there are eight time slots available for the program execution, which in this case will consist of one CNT and one ECMP instruction as shown below. The data field of the ECMP instruction is the 32-bit compare value, whereby the lower 7 bits represent the high resolution compare field.

When the 25-bit (loop resolution) compare matches, the HR compare value will be loaded from the 7 lower bits of the instruction data field to the HR counter. At the next loop resolution clock, the HR counter will count down at the HR clock frequency and perform the pin action when it reaches zero.

In the example illustrated by Figure 23-19 the 25-bit compare value is one and the 7-bit HR compare value is two. According to Section 23.2.3.2, depending on the loop resolution divide rate (lr), only certain bits of the 7-bit HR compare value are valid. In this example only the upper 2 bits (D[6:5]) are taken into account. The example program below has a setting of hr\_data = 100000b. Shifting this value right by 5 bits, results in 10b which equals the two HR clock cycles delay mentioned above.

**Figure 23-19. ECMP Execution Timings**

HETPFR[31:0] register = 0x201 --> lr=4 and hr=2 --> ts = 8

#### N2HET Program:

```
L00  CNT  { next= L01, reg=A, irq=OFF, max = 4 }
L01  ECMP { next= L00, cond_addr= L00, hr_lr=HIGH, en_pin_action=ON, pin=0,
          action=PULSEHI, reg=A, irq=OFF, data= 1, hr_data = 0x40 }
```

; 25 bit compare value is 1 and the 7-bit HR compare value is 2  
; (Because of lr=4 the D[4:0] of the 7-bit HR field are ignored )

#### NOTE: ECMP Opposite Actions

ECMP opposite pin actions are always synchronized to the loop resolution clock.

Changing the duty cycle of a PWM generated by an ECMP instruction, can lead to a missing pulse if the data field of the instruction is updated directly. This can happen when it is changed from a high value to a lower value while the CNT instruction has already passed the new updated lower value. To avoid this a synchronous duty cycle update can be performed with the use of an additional instruction (MOV32). This instruction is only executed when the compare of the ECMP matches. For this the cond\_addr of the ECMP needs to point to the MOV32. On execution of the MOV32, it moves its data field into the data field of the ECMP. The update of the duty cycle has to be made to the MOV32 data field instead of the ECMP data field.

### 23.2.5.10 PWM Generation Example 2 (in HR Mode)

The MCMP instruction can also be used in HR mode. In this case operation is exactly the same as for the ECMP instruction except that the 25-bit low resolution is now the result of a magnitude compare (greater or equal) rather than an equality compare. When the 25-bit (loop resolution) magnitude compare matches, the HR compare value will be loaded from the 7 lower bits of the instruction data field to the HR counter. At the next loop resolution clock, the HR counter will count down at the HR clock frequency and perform the pin action when it reaches zero.

The MCMP instruction avoids the missing pulse problem of the ECMP instruction (see previous example), however the duty cycle of the signal might not be exact for one PWM period. The benefit of the MCMP is that it avoids adding another instruction to do the duty cycle update synchronously.

### 23.2.5.11 Pulse Generation Example (in HR Mode)

The PWCNT instruction may also be used in HR mode to generate pulse outputs with HR width. It generates a single pulse when the data field of the instruction is non-zero. It remains at the opposite pin action when the data field is zero.

The PWCNT instruction operates conversely to the ECMP instruction. See [Figure 23-20](#). For PWCNT, the opposite pin action is synchronous with the HR clock and for ECMP the pin action is synchronous with the HR clock. The PWCNT pin action is synchronous with the loop resolution clock.

**Figure 23-20. High/Low Resolution Modes for ECMP and PWCNT**

### 23.2.5.12 Pulse Measurement Example (in HR Mode)

The PCNT instruction captures HR measurement of the high/low pulse time or periods of the input. As shown in [Figure 23-21](#), at marker (1) the input goes HIGH and the HR counter immediately begins to count. The counter increments and rolls over until the falling edge on the input pin, where it captures the counter value into the HR capture register (marker (2)). The PCNT instruction begins counting when the synchronized input signal goes HIGH and captures both the 25-bit data field and the HR capture register into RAM when the synchronized input falls (marker (3)).

**NOTE:** The HR capture value written into RAM is shifted appropriately depending on the loop resolution prescale divide rate (lr). (See also [Section 23.2.3.2](#), "The 7-bit HR data field")

[Figure 23-21](#) shows what happens when the capture edge arrives *after* the HR counter overflows. This causes the incremented value to be captured by the PCNT instruction.

**Figure 23-21. PCNT Instruction Timing (With Capture Edge After HR Counter Overflow)**

Figure 23-22 shows what happens when the capture edge arrives *before* the HR counter overflows. This causes the non-incremented value to be captured by the PCNT instruction.

**Figure 23-22. PCNT Instruction Timing (With Capture Edge Before HR Counter Overflow)**

### 23.2.5.13 WCAP Execution Example (in HR Mode)

The HR capability is enabled for WCAP, if its `hr_lr` bit is zero. In this case the HR counter is always enabled and is synchronized with the resolution loop. When the specified edge is detected, the current value of the HR counter is captured in the HR capture register and written into the RAM after the next WCAP execution. The WCAP instruction effectively time stamps the free running timer saved in a register (for example, register A shown in Figure 23-23).

**Figure 23-23. WCAP Instruction Timing**

HETPFR\_register = 0x0200 --> lr = 4, hr = 1, ts = 4

**N2HET Program:**

```
L00 CNT {reg=A, max=01ffffffh}
L01 WCAP {next=L00, cond_addr=L00, hr_lr=high, reg=A, event= FALL, pin=0,
data=0}
```

In the example, the WCAP is configured to capture the counter when a **falling** edge occurs. The WCAP data field (WCAP\_DF) is updated in the loop succeeding the loop in which the edge occurred. The WCAP instruction evaluates an edge by comparing its Previous bit with the sync'd input signal. In [Figure 23-23](#), the current value of the counter (4) is captured to WCAP\_DF[31:7] and the value of the HR capture register (2) is transferred to the valid bits (according the lr prescaler) of WCAP\_DF[6:0]. Therefore, in the example 0x0240 is captured in WCAP\_DF[31:0].

**23.2.5.14 I/O Pull Control Feature**
**Figure 23-24. I/O Block Diagram Including Pull Control Logic**

The following apply if the device is under reset:

- Pull control: The reset pull control on the pins is enabled and a pulldown is configured.
- Input buffer: The input buffer is enabled.
- Output buffer: The output buffer is disabled.

The following apply if the device is out of reset:

- Pull control: The pull control is enabled by clearing the corresponding bit in the N2HET Pull Disable Register (HETPULDIS). In this case, if the corresponding bit in the N2HET Pull Select Register (HETPSL) is set, the pin will have a pull-up; if the bit in the N2HET Pull Select Register (HETPSL) is cleared, the pin will have a pull-down. If the bit in the N2HET Pull Disable Register (HETPULDIS) is set, there is no pull-up or pull-down on the pin.
- Input buffer: The input buffer is disabled only if the pin direction is set to input AND the pull control is disabled AND pull down is selected as the pull bias. In all other cases, the input buffer is enabled.

**NOTE:** The pull-disable logic depends on the pin direction. If the pin is configured as output, then the pulls are disabled automatically. If the pin is configured as input, the pulls are enabled or disabled depending on the pull disable register bit.

- Output buffer: A pin can be driven as an output pin if the corresponding bit in the N2HET Direction Register (HETDIR) is set AND the open-drain feature (N2HET Open Drain Register (HETPDR)) is not enabled. See [Section 23.2.5.15, Open-Drain Feature](#) for more details.

The behavior of the input buffer, output buffer, and the pull control is summarized in [Table 23-9](#). When an input buffer is disabled, it appears as a logic low to on-chip logic.

**Table 23-9. Input Buffer, Output Buffer and Pull Control Behavior <sup>(1)</sup>**

| Device under Reset? | Pin Direction (DIR) | Pull Disable (PULDIS) | Pull Select (PULSEL) | Pull Control                | Output Buffer | Input Buffer |
|---------------------|---------------------|-----------------------|----------------------|-----------------------------|---------------|--------------|
| Yes                 | X                   | X                     | X                    | Device- and module-specific | Disabled      | Disabled     |
| No                  | 0                   | 0                     | 0                    | Pull down                   | Disabled      | Enabled      |
| No                  | 0                   | 0                     | 1                    | Pull up                     | Disabled      | Enabled      |
| No                  | 0                   | 1                     | 0                    | Disabled                    | Disabled      | Disabled     |
| No                  | 0                   | 1                     | 1                    | Disabled                    | Disabled      | Enabled      |
| No                  | 1                   | X                     | X                    | Disabled                    | Enabled       | Enabled      |

<sup>(1)</sup> X = Don't care

### 23.2.5.15 Open-Drain Feature

The following apply if the open-drain feature is enabled on a pin, that is, the corresponding bit in the N2HET Open Drain Register (HETPDR) is set

- Output buffer is enabled if a low signal is being driven internally to the pin.
- The output buffer is disabled if a high signal is being driven internally to the pin.

### 23.2.5.16 N2HET Pin Disable Feature

This feature is provided for the safe operation of systems such as power converters and motor drives. It can be used to inform the monitoring software of motor drive abnormalities such as over-voltage, over-current, and excessive temperature rise.

Figure 23-25. N2HET Pin Disable Feature Diagram

The following truth-table shows the conditions for the output buffer to be enabled/disabled.

Table 23-10. N2HET Pin Disable Feature

| HETPINDIS.x | nDIS Pin (Input) | HET PIN ENA (HETGCR.24) | HETDIR.x | Output Buffer |
|-------------|------------------|-------------------------|----------|---------------|
| 0           | X                | X                       | 0        | Disabled      |
| 0           | X                | X                       | 1        | Enabled       |
| 1           | 0                | X                       | 0        | Disabled      |
| 1           | 0                | X                       | 1        | Disabled      |
| 1           | 1                | X                       | 0        | Disabled      |
| 1           | 1                | 0                       | 1        | Disabled      |
| 1           | 1                | 1                       | 1        | Enabled       |

An interrupt capable device I/O pin can share the same pin as the N2HET nDIS signal. Normally GIOA[5] serves as nDIS for N2HET1 and GIOB[2] as nDIS for N2HET2. Check the device datasheet for the actual implementation. Sharing a pin with a GIO pin that is Interrupt capable allows the N2HET nDIS input to also generate an interrupt to the CPU. An active low level on nDIS is intended to signal an abnormal situation as described above. All N2HET pins, which are selected with the N2HET Pin Disable Register (HETPINDIS), will be put in the high-impedance state by hardware immediately after the nDIS signal is pulled low. At this time a CPU interrupt is issued, if it is enabled in the GIO pin logic.

The bit HET PIN ENA is automatically cleared in the failure condition and this state remains as long as the software explicitly sets the bit again. The steps to do this are:

- Software detects, by reading the HETDIN register of the GIO pin, that the level on nDIS is inactive (high).
- Software sets bit HET PIN ENA to deactivate the high impedance state of the pins.

### 23.2.6 Suppression Filters

Each N2HET pin is equipped with a suppression filter. If the pin is configured as an input it enables to filter out pulses shorter than a programmable duration. Each filter consists of a 10-bit down counter, which starts counting at a programmable preloaded value and is decremented using the VCLK2 clock.

- The counter starts counting when the filter input signal has the opposite state of the filter output signal. The output signal is preset to the same input signal state after reset, in order to ensure proper operation after device reset.
- Once the counter reaches zero without detecting an opposite pin state on the filter output signal, the output signal is set to the opposite state.
- When the counter detects an opposite pin action on the filter input signal before reaching zero, the counter is loaded with it's preload value and the opposite pin action on the filter output signal does not

take place. The counter resumes at the preload value until it detects an opposite pin action on the input signal again.

- Therefore the filter output signal is delayed compared to the filter input signal. The amount of delay depends on the counter clock frequency (VCLK2) and the programmed preload value.
- The accuracy of the output signal is +/- the counter clock frequency.

**Figure 23-26. Suppression Filter Counter Operation**

The following table gives examples for a 100 MHz VCLK2 frequency.

**Table 23-11. Pulse Length Examples for Suppression Filter**

| Divider<br>CCDIV | VCLK2     | Possible values for the suppressed pulse length / frequency resulting from the programmable 10 bit preload value (0,1,...,1023) |                                                |
|------------------|-----------|---------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|
| 1                | 100.0 MHz | 10 ns, 20 ns, ..., 10.22 $\mu$ s, 10.23 $\mu$ s                                                                                 | 50 MHz, 25 MHz, ..., 48.924 kHz, 48.876 kHz    |
| 2                | 50.0 MHz  | 20 ns, 40 ns, ..., 20.44 $\mu$ s, 20.48 $\mu$ s                                                                                 | 25 MHz, 12.5 MHz, ..., 24.462 kHz, 24.414 kHz  |
| 3                | 33.3 MHz  | 30 ns, 60 ns, ..., 30.66 $\mu$ s, 30.69 $\mu$ s                                                                                 | 16.7 MHz, 8.3 MHz, ..., 16.308 kHz, 16.292 kHz |

### 23.2.7 Interrupts and Exceptions

N2HET interrupts can be generated by any instruction that has an interrupt enable bit in its instruction format. When the interrupt condition in an instruction is true and the interrupt enable bit of that instruction is set an interrupt flag is then set in the N2HET Interrupt Flag Register (HETFLG). The address code for this flag is determined by the five LSBs of the current timer program address. The flag in the N2HET Interrupt Flag Register (HETFLG) is set even if the corresponding bit in the N2HET Interrupt Enable Set Register (HETINTENAS) is zero. To generate an interrupt the corresponding bit in the N2HET Interrupt Enable Set Register (HETINTENAS) must be one. In the N2HET interrupt service routine, the main CPU must first determine which source inside the N2HET created the interrupt request. This operation is accelerated by the N2HET Offset Index Priority Level 1 Register (HETOFF1) or N2HET Offset Index Priority Level 2 Register (HETOFF2) which automatically provide the number of the highest priority source within each priority level. Reading the offset register will automatically clear the corresponding N2HET interrupt flag which created the request. However, if the offset registers are not used by the N2HET interrupt service routine, the flag should be cleared explicitly by the CPU once the interrupt has been serviced.

**Table 23-12. Interrupt Sources and Corresponding Offset Values in Registers HETOFFx**

| Source No.                | Offset Value |
|---------------------------|--------------|
| no interrupt              | 0            |
| Instruction 0, 32, 64...  | 1            |
| Instruction 1, 33, 65...  | 2            |
| :                         | :            |
| Instruction 31, 63, 95... | 32           |
| Program Overflow          | 33           |
| APCNT underflow:          | 34           |
| APCNT overflow            | 35           |

The instructions capable of generating interrupts are listed in [Table 23-51](#).

**Figure 23-27. Interrupt Functionality on Instruction Level**

Each interrupt source is associated with a priority level (level 1 or level 2). When multiple interrupts with the same priority level occur during the same loop resolution the lowest flag bit is serviced first.

In addition to the interrupts generated by the instructions the N2HET can generate three additional exceptions:

- Program overflow
- APCNT underflow (see [Section 23.3.1.2](#))
- APCNT overflow (see [Section 23.3.1.3](#))

### 23.2.8 Hardware Priority Scheme:

If two or more software interrupts are pending on the same priority level, the offset value will show the one with the highest priority. The interrupt with the highest priority is the one with the lower offset value. This scheme is hard-wired in the offset encoder. See [Figure 23-28](#).

**Figure 23-28. Interrupt Flag/Priority Level Architecture**

### 23.2.9 N2HET Requests to DMA and HTU

As described in [Section 23.5.3](#) the majority of the N2HET instructions are able to generate a transfer request to the High End Timer Transfer Unit (HTU) and/or to the DMA module when an instruction-specific condition is true. One N2HET instruction can select one of 8 request lines by programming the “reqnum” parameter (see [Section 23.5.3](#)). The “request” field in an instruction is used to enable, disable, or to generate a quiet request (see [Section 23.5.2](#)) on the selected request line. Quiet requests can be used by the HTU, but not by the DMA. For quiet request please refer to the HTU users guide.

The configuration of the N2HET Request Destination Select Register (HETREQDS) bits determines if a request line triggers an HTU-DCP, a DMA channel or both. This means the register bits will determine whether an N2HET instruction triggers DMAREQ[x], HTUREQ[x] or both signals (shown in [Figure 23-29](#)). The request line number x corresponds to the “reqnum” parameter used in the instruction.

**Figure 23-29. Request Line Assignment Example**

## 23.3 Angle Functions

Engine management systems require an angle-referenced time base to synchronize signals to the engine toothed wheel. The N2HET has a method to provide such a time base for low-end engine systems. The reference is created by the N2HET using three dedicated instructions with fractional angle steps equal to  $/8$ ,  $/16$ ,  $/32$ ,  $/64$ .

### 23.3.1 Software Angle Generator

The N2HET provides three specialized count instructions to generate an angle referenced time base synchronized to an external reference signal (the toothed wheel signal) that defines angular reference points.

The time base is used to generate fractional angle steps between the reference points. The step width  $K$  ( $= 8, 16, 32$ , or  $64$ ) programmed by the user defines the angle accuracy of the time base. These fractional steps are then accumulated in an angle counter to form the absolute angle value.

The first counter, APCNT, incremented on each loop resolution clock measures the periods  $P(n)$  of the external signal. The second counter SCNT counts by step  $K$  up to the previous period value  $P(n-1)$ , measured by APCNT, and then recycles. The resulting period of SCNT is the fraction  $P(n-1) / K$ . The third counter ACNT accumulates the fractions generated by SCNT.

[Figure 23-30](#) illustrates the basic operation of APCNT, SCNT, and ACNT.

A N2HET timer program can only have one angle generator.

**Figure 23-30. Operation of N2HET Count Instructions**

Due to stepping, the final count of SCNT does not usually exactly match the target value  $P(n-1)$ .

[Figure 23-31](#) illustrates how SCNT compensates for this feature by starting each cycle with the remainder (final count - target) of the previous cycle.

**Figure 23-31. SCNT Count Operation**

ACNT detects period variations of the external signal measured by APCNT and compensates related counting errors. A period increase is flagged in the deceleration flag. A period decrease is flagged in the acceleration flag. If no variation is flagged, ACNT increments the counter value each time SCNT reaches its target. If acceleration is detected, ACNT increments the counter value on each timer resolution (fast mode). If deceleration is detected, ACNT is stopped. Figure 23-32 illustrates how the compensations for acceleration and deceleration operate.

**Figure 23-32. ACNT Period Variation Compensations**

### 23.3.1.1 Singularities

Singularities (gaps, in this case, from missing teeth in a toothed wheel) in the external reference signal can be masked. The start and end of singularities are defined by gap start and gap end values specified in SCNT and ACNT. When ACNT reaches gap start or gap end, it sets/resets the gap flag.

While the gap flag is set, new periods of the external reference signal are ignored for angle computation. SCNT uses the last period measured by APCNT just before gap start.

Figure 23-33 and Figure 23-34 illustrate the behavior of the angle generator during a gap after a deceleration or acceleration of the N2HET.

**Figure 23-33. N2HET Timings Associated with the Gap Flag (ACNT Deceleration)**

**Figure 23-34. N2HET Timings Associated with the Gap Flag (ACNT Acceleration)**

### 23.3.1.2 APCNT Underflow

The fastest valid external signal APCNT can accept must satisfy the following condition:

Step Width  $K < \text{Period Min. Resolution (LRP)}$

This condition fixes the maximum possible step width once the minimum period and the resolution of an application are specified.

If a period value accidentally falls below the minimum allowed, APCNT stops the capture of these periods and sets the APCNT underflow interrupt flag located in the exceptions interrupt control register. In such a situation, SCNT and ACNT continue to be executed using the last valid period captured by APCNT.

### 23.3.1.3 APCNT Overflow

The slowest valid external signal APCNT can measure must satisfy the following condition:

Period Max Resolution  $< 33554431$

When this limit is reached (APCNT Count equals all 1's), APCNT stays at a maximum count (stops counting). APCNT remains in this position until the next specified capture edge is detected on the selected pin and sets the APCNT overflow interrupt flag located in the exceptions interrupt control register. In this situation, SCNT and ACNT continue to be executed using the maximum APCNT period count.

## 23.4 N2HET Control Registers

Table 23-13 summarizes all the N2HET registers. The base address for the control registers is FFF7 B800h for N2HET1 and FFF7 B900h for N2HET2.

**Table 23-13. N2HET Registers**

Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Table 23-14. Global Configuration Register (HETGCR) Field Descriptions (continued)**

| Bit | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----|-------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | TO    |       | <p>Turn On/Off</p> <p>When TO = 0, the timer program stops executing. Turn-off is automatically delayed until the current timer program loop is completed. Turn-off does not affect the content of the timer RAM, ALU registers, or control registers. Turn-off resets all flags.</p> <p>TO does not affect the state of the pins. You must set/reset the timer pins when they are turned off, or re-initialize the timer RAM and control registers before a reset. After a device reset, the timer is turned off by default.</p> <p>When TO = 1, timer program execution starts synchronously to the Loop clock. In case of multiple N2HETs configuration, the slave N2HETs are waiting for the loop clock to come from the master before starting execution. Then, the timer address points automatically address 00h (corresponding to program start).</p> |
|     |       | 0     | N2HET is OFF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|     |       | 1     | N2HET is ON.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### 23.4.2 Prescale Factor Register (HETPFR)

N2HET1: offset = FFF7 B804h; N2HET2: offset = FFF7 B904h

**Figure 23-36. Prescale Factor Register (HETPFR)**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 23-15. Prescale Factor Register (HETPFR) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                         |
|-------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-11 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                              |
| 10-8  | LRPFC    |       | <p>Loop Resolution Pre-scale Factor Code</p> <p>LRPFC determines the loop resolution prescale divide rate (lr). See <a href="#">Table 23-5</a>.</p> |
| 7-6   | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                              |
| 5-0   | HRPFC    |       | <p>High Resolution Pre-scale Factor Code</p> <p>HRPFC determines the high resolution prescale divide rate (hr). See <a href="#">Table 23-5</a>.</p> |

### 23.4.3 N2HET Current Address Register (HETADDR)

**N2HET1:** offset = FFF7 B808h; **N2HET2:** offset = FFF7 B908h

**Figure 23-37. N2HET Current Address (HETADDR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 23-16. N2HET Current Address (HETADDR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                |
|------|----------|-------|------------------------------------------------------------------------------------------------------------|
| 31-9 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                     |
| 8-0  | HETADDR  |       | N2HET Current Address<br>Read: Returns the current N2HET program address.<br>Write: Writes have no effect. |

### 23.4.4 Offset Index Priority Level 1 Register (HETOFF1)

**N2HET1:** offset = FFF7 B80Ch; **N2HET2:** offset = FFF7 B90Ch

**Figure 23-38. Offset Index Priority Level 1 Register (HETOFF1)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 23-17. Offset Index Priority Level 1 Register (HETOFF1) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-6 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 5-0  | OFFSET1  |       | HETOFF1[5:0] indexes the currently pending high-priority interrupt. Offset values and sources are listed below and the interrupt encoding format is presented in <a href="#">Table 23-18</a> .<br>Read: Read of these bits determines the pending N2HET interrupt.<br>Write: Writes have no effect.<br><b>Note:</b> In any read operation mode, the corresponding flag (in the HETFLG) is also cleared. In Emulation mode the corresponding flag is not cleared. |

**Table 23-18. Interrupt Offset Encoding Format**

| Source No.                | Offset Value |
|---------------------------|--------------|
| No interrupt              | 0            |
| Instruction 0, 32, 64...  | 1            |
| Instruction 1, 33, 65...  | 2            |
| :                         | :            |
| Instruction 31, 63, 95... | 32           |
| Program Overflow          | 33           |
| APCNT Underflow           | 34           |
| APCNT Overflow            | 35           |

### 23.4.5 Offset Index Priority Level 2 Register (HETOFF2)

**N2HET1:** offset = FFF7 B810h; **N2HET2:** offset = FFF7 B910h

**Figure 23-39. Offset Index Priority Level 2 Register (HETOFF2)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 23-19. Offset Index Priority Level 2 Register (HETOFF2) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-6 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 5-0  | OFFSET2  |       | <p>HETOFF2[5:0] indexes the currently pending low-priority interrupt. Offset values and sources are listed above and the interrupt encoding format is presented in <a href="#">Table 23-18</a>.</p> <p>Read: Read of these bits determines the pending N2HET interrupt.</p> <p>Write: Writes have no effect.</p> <p><b>Note:</b> In any read operation mode, the corresponding flag (in the HETFLG) is also cleared. In Emulation mode the corresponding flag is not cleared.</p> |

### 23.4.6 Interrupt Enable Set Register (HETINTENAS)

**N2HET1:** offset = FFF7 B814h; **N2HET2:** offset = FFF7 B914h

**Figure 23-40. Interrupt Enable Set Register (HETINTENAS)**

| 31-0 | HETFLAG |       | Interrupt Flag Register Bits<br>Bit x is set when an interrupt condition has occurred on one of the instructions x+0, x+32, x+64.... The flag position x (in the register) is decoded from the five LSBs of the instruction address that generated the interrupt. The hardware will set the flag only if the interrupt enable bit (in the corresponding instruction) is set. The flag will be set even if bit x in the Interrupt Enable Set Register (HETINTENAS) is not enabled. Enabling bit x in HETINTENAS is required if an interrupt should be generated.<br>Clearing the flag can be done by writing a one to the flag. Alternatively reading the corresponding Offset Index Priority Level 1 Register (HETOFF1) or Offset Index Priority Level 2 Register (HETOFF2) will automatically clear the flag. |
|      |         | 0     | Read: No N2HET instruction with an interrupt has been reached since the flag was cleared.<br>Write: No effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | HETPDR n | 0     | Open drain control for HET[n] pins<br>The pin is configured in push/pull mode.                                                                                                                                                           |
|      |          | 1     | The pin is configured in open drain mode. The HETDOUT register controls the state of the output buffer:<br>HETDOUT[n] = 0 The output buffer of pin HET[n] is driven low.<br>HETDOUT[n] = 1 The output buffer of pin HET[n] is tristated. |

### 23.4.24 N2HET Pull Disable Register (HETPULDIS)

Values in this register enable or disable the pull-up/-down functionality of the pins.

**N2HET1:** offset = FFF7 B864h; **N2HET2:** offset = FFF7 B964h

**Figure 23-58. N2HET Pull Disable Register (HETPULDIS)**

|           |    |
|-----------|----|
| 31        | 16 |
| HETPULDIS |    |
| R/W-n     |    |
| 15        | 0  |
| HETPULDIS |    |
| R/W-n     |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; n is device dependent, see device specific data sheet

**Table 23-38. N2HET Pull Disable Register (HETPULDIS) Field Descriptions**

| Bit  | Field       | Value | Description                                                                     |
|------|-------------|-------|---------------------------------------------------------------------------------|
| 31-0 | HETPULDIS n | 0     | Pull disable for N2HET pins<br>The pull functionality is enabled on pin HET[n]. |
|      |             | 1     | The pull functionality is disabled on pin HET[n].                               |

**NOTE:** See device data sheet for which pins provide programmable pullups/pulldowns.

[Table 23-9](#) shows how the register bits of HETDIR, HETPULDIS and HETPSL are affecting the N2HET pins.

### 23.4.25 N2HET Pull Select Register (HETPSL)

Values in this register select the pull-up or pull-down functionality of the pins.

**N2HET1:** offset = FFF7 B868h; **N2HET2:** offset = FFF7 B968h

**Figure 23-59. N2HET Pull Select Register (HETPSL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 23-39. N2HET Pull Select Register (HETPSL) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                 |
|------|----------|-------|-------------------------------------------------------------------------------------------------------------|
| 31-0 | HETPSL n | 0     | Pull select for NHET pins<br>The pull down functionality is enabled if corresponding bit in HETPULDIS is 0. |
|      |          | 1     | The pull up functionality is enabled if corresponding bit in HETPULDIS is 0.                                |

**NOTE:** See device data sheet for which pins provide programmable pullups/pulldowns.

[Table 23-9](#) shows how the register bits of HETDIR, HETPULDIS and HETPSL are affecting the N2HET pins.

The information of this register is also used to define the pin states after a parity error:

After a parity error all N2HET pins, which are

1. Defined as output pins in the HETDIR register
2. Not defined as open drain pins (with the HETPDR register)
3. Selected with the HETPPR register, will remain outputs, but automatically change their levels in the following way:
  - If the HETPSL register specifies 0 for the pin, it will switch to low level.
  - If the HETPSL register specifies 1 for the pin, it will switch to high level.

This behavior is independent of the value, which register HETPULDIS specifies for the corresponding pin.

### 23.4.26 Parity Control Register (HETPCR)

**N2HET1:** offset = FFF7 B874h; **N2HET2:** offset = FFF7 B974h

**Figure 23-60. Parity Control Register (HETPCR)**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 23-40. Parity Control Register (HETPCR) Field Descriptions**

| Bit  | Field      | Value  | Description                                                                                                                                                                                                                                                                                                            |
|------|------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-9 | Reserved   | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                 |
| 8    | TEST       | 0      | Test Bit. When this bit is set, the parity bits are mapped into the peripheral RAM frame to make them accessible by the CPU.<br>Read: Parity bits are not memory mapped.<br>Write: Disable mapping.                                                                                                                    |
|      |            | 1      | Read: Parity bits are memory mapped.<br>Write: Enable mapping.                                                                                                                                                                                                                                                         |
| 7-4  | Reserved   | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                 |
| 3-0  | PARITY_ENA | 5h     | Enable/disable parity checking. This bit field enables or disables the parity check on read operations and the parity calculation on write operations. If parity checking is enabled and a parity error is detected the N2HET_UERR signal is activated.<br>Read: Parity check is disabled.<br>Write: Disable checking. |
|      |            | Others | Read: Parity check is enabled.<br>Write: Enable checking.                                                                                                                                                                                                                                                              |

**NOTE:** It is recommended to write an "Ah" to enable error detection, to guard against soft errors flipping PARITY\_ENA to a disable state.

### 23.4.27 Parity Address Register (HETPAR)

**N2HET1:** offset = FFF7 B878h; **N2HET2:** offset = FFF7 B978h

**Figure 23-61. Parity Address Register (HETPAR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; X = Value unchanged after reset

**Table 23-41. Parity Address Register (HETPAR) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-13 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 12-2  | PAOFF    |       | <p>Parity Error Address Offset. This register holds the offset address of the first parity error, which is detected in N2HET RAM. This error address is frozen from being updated until it is read by the CPU. During emulation mode, this address is frozen even when read.</p> <p>In case of a N2HET RAM parity error, PAOFF will contain the offset address of the erroneous 32-bit N2HET RAM field counted from the beginning of the N2HET RAM.</p> <p>Examples: The 32-bit program field of instruction 0 will return 0, the 32-bit control field of instruction 0 will return 1, ..., the 32-bit control field of instruction 1 will return 5, and so on.</p> <p>Read: Returns the offset address of the erroneous 32-bit word in bytes from the beginning of the N2HET RAM.</p> <p>Write: Writes have no effect.</p> |
| 1-0   | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**NOTE:** The Parity Error Address Register will not be reset, neither by PORRST nor by any other reset source.

### 23.4.28 Parity Pin Register (HETPPR)

**N2HET1:** offset = FFF7 B87Ch; **N2HET2:** offset = FFF7 B97Ch

### Figure 23-62. Parity Pin Register (HETPPR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

### Table 23-42. Parity Pin Register (HETPPR) Field Descriptions

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                       |
|------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | HETPPR n |       | NHET Parity Pin Select Bits - Allows HET[n] pins to be configured to drive to a known state when an N2HET parity error is detected.                                                                                                               |
|      |          | 0     | Pin HET[n] is not affected by the detection of an N2HET parity error.                                                                                                                                                                             |
|      |          | 1     | Pin HET[n] is driven to a known state when an N2HET parity error is detected. The known state is a function of bits HETDIR[n], HETPSL[n], HETPDR[n] as described in <a href="#">Table 23-43</a> (this state is also independent of HETPULDIS[n]). |

### Table 23-43. Known State on Parity Error

| HETDIR[n] | HETPDR[n] | HETPSL[n] | Known State on Parity Error |
|-----------|-----------|-----------|-----------------------------|
| 0         | x         | x         | High Impedance              |
| 1         | 0         | 0         | Drive Logic 0               |
| 1         | 0         | 1         | Drive Logic 1               |
| 1         | 1         | x         | High Impedance              |

### 23.4.29 Suppression Filter Preload Register (HETSFPRLD)

**N2HET1:** offset = FFF7 B880h; **N2HET2:** offset = FFF7 B980h

**Figure 23-63. Suppression Filter Preload Register (HETSFPRLD)**

<sup>(1)</sup> Cycles refers to the clock cycle of the N2HET module; which on most devices is VCLK2. (Check the device datasheet description of clock domains to confirm). If the high resolution prescale value is set to /1, then this is also the same as the number of HR clock cycles.

**Table 23-50. FLAGS Generated by Instruction**

| Abbreviation | Flag Name                | Set/Reset by                                                     | Used by                                             |
|--------------|--------------------------|------------------------------------------------------------------|-----------------------------------------------------|
| C            | Carry Flag               | ADC, ADD, AND, OR, RCNT, SBB, SUB, XOR                           | ADC, BR, SBB                                        |
| N            | Negative Flag            | ADC, ADD, AND, OR, SBB, SUB, XOR                                 | BR                                                  |
| V            | Overflow Flag            | ADC, ADD, AND, OR, SBB, SUB, XOR                                 | BR                                                  |
| Z            | Zero flag                | ACNT, ADC, ADD, AND, APCNT, CNT, OR, PCNT, SBB, SCNT, SHFT, XOR, | ACMP, ACNT, BR, ECMP, MCMP, MOV32, RCNT, SCMP, SHFT |
| X            | Angle Compare Match Flag | ACMP                                                             | SCMP                                                |
| SWF 0-1      | Step width flags         | SCNT                                                             | ACNT                                                |
| NAF          | New Angle Flag           | ACNT                                                             | NAF_global                                          |
| NAF_global   | New Angle flag (global)  | HWAG or NAF                                                      | ACMP, BR, CNT, ECMP, ECNT                           |
| ACF          | Acceleration flag        | ACNT                                                             | ,ACNT, SCNT                                         |
| DCF          | Deceleration flag        | ACNT                                                             | ,ACNT, SCNT                                         |
| GPF          | Gap flag                 | ACNT                                                             | ACNT, APCNT                                         |

The instructions capable of generating SW interrupts are listed in [Table 23-51](#).

**Table 23-51. Interrupt Capable Instructions**

| Interrupt Capable Instructions | Non Interrupt Capable Instructions |
|--------------------------------|------------------------------------|
| ACMP                           | ADC                                |
| ACNT                           | ADCNST                             |
| APCNT                          | ADD                                |
| BR                             | ADM32                              |
| CNT                            | AND                                |
| DJZ                            | DADM32                             |
| ECMP                           | MOV32                              |
| ECNT                           | MOV64                              |
| MCMP                           | OR                                 |
| PCNT                           | RADM64                             |
| PWCNT                          | RCNT                               |
| SCMP                           | SBB                                |
| SHFT                           | SCNT                               |
| WCAP                           | SUB                                |
| WCAPE                          | XOR                                |

### 23.5.2 Abbreviations, Encoding Formats and Bits

Abbreviations marked with a star (\*) are available only on specific instructions.

|                 |                                                                                                                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>U</b>        | Reading a bit marked with U will return an indeterminate value.                                                                                                                                         |
| <b>BRK</b>      | Defines the software breakpoint for the device software debugger.<br>Default: OFF<br>Location: Program field [22]                                                                                       |
| <b>next</b>     | Defines the program address of the next instruction in the program flow. This value may be a label or an 9-bit unsigned integer.<br>Default: Current instruction + 1<br>Location: Program field [21:13] |
| <b>reqnum*</b>  | Defines the number of the request line (0,1,...,7) to trigger either the HTU or the DMA.<br>Default: 0<br>Location: Program field [25:23]                                                               |
| <b>request*</b> | Allows to select between no request (NOREQ), request (GENREQ) and quiet request (QUIET). See <a href="#">Section 23.2.9</a> .<br>Default: No request<br>Location: Control Field [28:27]                 |

| Request | C[28] | JC[27] | To HTU        | To DMA     |
|---------|-------|--------|---------------|------------|
| NOREQ   | 0     | 0      | no request    | no request |
|         | 1     | 0      |               |            |
| GENREQ  | 0     | 1      | request       | request    |
| QUIET   | 1     | 1      | quiet request | no request |

|                       |                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>remote*</b>        | Determines the 9-bit address of the remote address for the instruction.<br>Default: Current instruction + 1<br>Location: Program field [8:0]                                                         |
| <b>control</b>        | Determines whether the immediate data field [31:0] is cleared when it is read. When the bit is not set, reads do not clear the immediate data field.<br>Default: OFF<br>Location: Control field [26] |
| <b>en_pin_action*</b> | Determines whether the selected pin is ON so that the action occurs on the chosen pin<br>Default: OFF<br>Location: Control field [22]                                                                |
| <b>Cond_addr*</b>     | Conditional address (optional): Defines the address of the next instruction when the condition occurs.<br>Default: Current address + 1<br>Location: Control field [21:13]                            |
| <b>Pin*</b>           | Pin Select: Selects the pin on which the action occurs. Enter the pin number.<br>Default: pin 0<br>Location: Control field [12:8] except PCNT                                                        |

The format CC{pin number} is also supported.

| MSB                                                        |   |   |   | LSB | Description    |
|------------------------------------------------------------|---|---|---|-----|----------------|
| 0                                                          | 0 | 0 | 0 | 0   | Select HET[0]  |
| 0                                                          | 0 | 0 | 0 | 1   | Select HET[1]  |
| (Each pin may be selected by writing its number in binary) |   |   |   |     |                |
| 1                                                          | 1 | 1 | 1 | 0   | Select HET[30] |
| 1                                                          | 1 | 1 | 1 | 1   | Select HET[31] |

### Reg\*

Register select: Selects the register for data comparison and storage

Default: No register (None)

Location: Control field [2:1] except for CNT instruction.

Extended Register Select C[7] is available for ACMP, ADC, ADD, ADM32, AND, DADM64, ECMP, ECNT, MCMP, MOV32, MOV64, OR, RADM64, SBB, SHFT, SUB, WCAP, WCAPE instructions.

| Register | Ext Reg. C[7] | C[2] | C[1] |
|----------|---------------|------|------|
| A        | 0             | 0    | 0    |
| B        | 0             | 0    | 1    |
| T        | 0             | 1    | 0    |
| None     | 0             | 1    | 1    |
| R        | 1             | 0    | 0    |
| S        | 1             | 0    | 1    |
| Reserved | 1             | 1    | 0    |
| Reserved | 1             | 1    | 1    |

### Action\*

(2 Action Option) Either sets or clears the pin

Default: Clear

Location: Control Field [4]

| Action | C[4] |
|--------|------|
| Clear  | 0    |
| Set    | 1    |

### Action\*

(4 Action Option) Either sets, clears, pulse high or pulse low on the pin. Set/clear are single pin actions, pulse high/low include the opposite pin action.

Default: Clear

Location: Control Field [4:3]

| Action     | Action Type                                               | C[4] | C[3] |
|------------|-----------------------------------------------------------|------|------|
| Clear      | Set low on match                                          | 0    | 0    |
| Set        | Set high on match                                         | 1    | 0    |
| Pulse Low  | Set low on match + reset to high on Z=1 (opposite action) | 0    | 1    |
| Pulse High | Set high on match + reset to low on Z=1 (opposite action) | 1    | 1    |

**hr\_lr\*** Specifies HIGH/LOW data resolution. If the hr\_lr field is HIGH, the instruction uses the hr\_data field. If the hr\_lr field is LOW, the hr\_data field is ignored.  
Default: HIGH  
Location: Program Field [8]

| hr_lr | Prog. field [8] |
|-------|-----------------|
| LOW   | 1               |
| HIGH  | 0               |

**prv\*** Specifies the initial value defining the previous bit (see [Section 23.2.5.8](#)). A value of ON sets the previous pin-level bit to 1. A value of OFF sets the initial value of the previous (prv) bit to 0. The prv bit is overwritten (set or reset) by the N2HET the first time the instruction is executed.

Default: OFF

Location: Control Field [25]

**cntl\_val\*** Available for DADM64, MOV64, and RADM64, this bit field allows the user to specify the replacement value for the remote control field.

**comp\_mode\*** Specifies the compare mode. This field is used with the 64-bit move instructions. This field ensures that the sub-opcodes are moved correctly.

Default: ECMP

Location: Control Field [6:5]

| Action | C[6] | C[5] | order       |
|--------|------|------|-------------|
| ECMP   | 0    | 0    |             |
| SCMP   | 0    | 1    |             |
| MCMP1  | 1    | 0    | REG_GE_DATA |
| MCMP2  | 1    | 1    | DATA_GE_REG |

### 23.5.3 Instruction Description

The following sections provide information for individual instructions.

Parameters in [] are optional. Refer to the N2HET assembler user guide for the default values when parameters are omitted.

#### 23.5.3.1 ACMP (Angle Compare)

**Syntax**

```

ACMP {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [reqnum={3-bit unsigned integer}]
    [request={NOREQ | GENREQ | QUIET}]
    [control={OFF | ON}]
    [en_pin_action={OFF | ON}]
    [cond_addr={label | 9-bit unsigned integer}]
    pin={pin number}
    [action={CLEAR | SET}]
    reg={A | B | R | S | T | NONE}
    [irq = {OFF | ON}]
    data={25-bit unsigned integer}
}
    
```

**Figure 23-68. ACMP Program Field (P31:P0)**

**Figure 23-69. ACMP Control Field (C31:C0)**

**Figure 23-70. ACMP Data Field (D31:D0)**

**Cycles** One

**Register modified** Selected register (A, B, R, S, or T)

The purpose of the comparison is to assert pin action when the angle compare value lies between the old counter value and the new counter value (held in the selected register). Since the angle increment varies from one loop resolution clock to another, an exact equality test cannot be applied. Instead, the following inequality is used to determine the occurrence of a match:

$$\text{Old counter value} < \text{Angle compare value} \leq \text{New counter value}$$

This is done by performing following comparisons:

Selected register value minus angle increment < angle compare value

Angle compare value ≤ Selected register value

|                 |                                                                                                                                                                                                                                |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>register</b> | Register B is recommended for typical applications with ACMP.                                                                                                                                                                  |
| <b>irq</b>      | Specifies whether or not an interrupt is generated. Specifying ON generates an interrupt when the edge state is satisfied and the gap flag is set. Specifying OFF prevents an interrupt from being generated.<br>Default: OFF. |
| <b>data</b>     | Specifies the 25-bit angle compare value.                                                                                                                                                                                      |

## Execution

```

X = 0;
If (Data <= Selected Register)
    Cout = 0;
else
    Cout = 1;
If (Z == 0 AND (Selected Register - Angle Inc. < Data ) AND Cout == 0) OR
    (Z == 1 AND (Cout_prv == 1 OR Cout == 0))
{
    X = 1;
    If (Enable Pin Action == 1)
        Selected Pin = Pin Action AT next loop resolution clock;

    If (Interrupt Enable == 1)
        HETFLG[n] = 1; /* n depends on address */
    If ([C28:C27] == 01)
        Generate request on request line [P25:P23];
    If ([C28:C27] == 11)
        Generate quiet request on request line [P25:P23];

    Jump to Conditional Address;
}
else
    Jump to Next Program Address;

Cout_prv = Cout (always executed)

```

---

### NOTE: Carry-Out Signal (Cout)

Cout is the carry-out signal of the adder. Even if it is not a flag, it is valid all along ACMP instruction execution.

---

Angle inc. = NAF\_global or hardware angle generator 11-bit input.

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

### 23.5.3.2 ACNT (Angle Count)

#### Syntax

```
ACNT {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [reqnum={3-bit unsigned integer}]
    [request={NOREQ | GENREQ | QUIET}]
    edge={RISING | FALLING}
    [irq = {OFF | ON}]
    [control={OFF | ON}]
    [prv={OFF | ON}]
    gapend = {25-bit unsigned integer}
    data={25-bit unsigned integer}
}
```

**Figure 23-71. ACNT Program Field (P31:P0)**

**Figure 23-72. ACNT Control Field (C31:C0)**

**Figure 23-73. ACNT Data Field (D31:D0)**

#### Cycles

Two, as follows:

- First cycle: Angle increment condition and gap end comparison.
- Second cycle: Gap start comparison.

#### Register modified

Register B (angle value)

#### Description

This instruction defines a specialized virtual timer used after SCNT and APCNT to generate an angle-referenced time base that is synchronized to an external signal (that is, a toothed wheel signal). ACNT uses pin HET[2] exclusively. The edge select must be the same as the HET[2] edge which was selected in the previous APCNT.

ACNT refers to the same step width selection that the previous SCNT saved in flags SWF0 and SWF1 (see information on SCNT).

ACNT detects period variations of the external signal measured by APCNT and compensates related count errors.

A period increase is flagged in the deceleration flag (DCF). A period decrease is flagged in the acceleration flag (ACF). If no variation is detected, ACNT increments the counter value each time SCNT reaches its target.

If acceleration is detected, ACNT increments the counter value on each timer resolution. If deceleration is detected ACNT does not increment and is thus saturated.

ACNT also specifies the gap end angle value defining the end value of a gap range in ACNT where period measurements in APCNT are temporarily stopped to mask singularities in the external signal. ACNT uses register A containing gap start and register B to store the counter value.

**Edge** Specifies the edge for the input capture pin (HET[2]).

| Action  | P8 | Edge Select                      |
|---------|----|----------------------------------|
| Rising  | 1  | Detects a rising edge of HET[2]  |
| Falling | 0  | Detects a falling edge of HET[2] |

**irq** ON generates an interrupt when the edge state is satisfied and the gap flag is set. OFF prevents an interrupt from being generated.  
Default: OFF.

**gapend** Defines the 25-bit end value of a gap range. The start value is defined in the SCNT instruction.  
 $GAPEND = (\text{Step Value} * (\# \text{ of teeth on the toothed wheel} + \# \text{ of missing teeth})) - 1$

**data** Specifies the 25-bit initial count value for the data field.  
Default: 0.

#### NOTE: Target Edge Field

The target edge field represents the three LSBs of data field register in case of step width = 8, four LSBs for step width = 16, five LSBs for step width = 32 and six LSBs for step width = 64.

#### Execution

**Increment Condition:** ((Z = 1 AND DCF = 0) OR ACF = 1)

**Pin Edge Condition:** Specified edge detected on HET[2]

**Target Edge Condition:** (Target Edge field in data field = 0) AND (Angle Increment condition is true) AND (GPF = 0)

If (Angle Increment Condition) is false

```
{
    NAF = 0;
    Register B = Data field register;
}
else
{
    NAF = 1;
    If (Counter value != GapEnd)
    {
        Register B = Data field register + 1;
        Data Field Register = Counter value + 1;
    }
}
```

```

        else
        {
            Register B = 0;
            Data Field Register = 0;
            If (ACF == 0) DCF = 1;
        }
    }

    Z = 0;

    If (Data field register == GapStart)
    {
        GPF = 1;
        If (Target Edge condition is true)
        {
            ACF = 0;
            If ((specified edge is not detected on pin HET[2]) AND (data
            field register != 0) AND (ACF == 0) AND (angle increment condition
            is true))
                DCF = 1;
        }
        If (specified edge is detected on pin HET[2])
        {
            DCF = 0;
            If ((target_edge_field != 0) AND (DCF == 0)) ACF = 1;
            If (GPF == 1)
            {
                GPF = 0;
                Z = 1;
                If (Interrupt Enable == 1)
                {
                    HETFLG[n] = 1;          /* n depends on address */
                    If ([C28:C27] == 01)
                        Generate request on request line [P25:P23];;
                    If ([C28:C27] == 11)
                        Generate quiet request on request line
                        [P25:P23];
                }
            }
        }
    }

    If ((target_edge_field != 0) and (pin_edge_cond == 1))
    {
        pin_update = 0;
    }
    else if (target_edge_field == 0)
    {
        pin_update = 1;
    }

    If (pin_update is true in next loop clock cycle)
    {
        Prv bit = Current Lx value of HET[2] pin;
    }

    Jump to next program address;

```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

### 23.5.3.3 ADCNST (Add Constant)

**Syntax**

```

ADCNST {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [control={OFF | ON}]
    remote={label | 9-bit unsigned integer}
    min_off={25-bit unsigned integer}
    data={25-bit unsigned integer}
    [hr_data={7-bit unsigned integer}]
}

```

**Figure 23-74. ADCNST Program Field (P31:P0)**

**Figure 23-75. ADCNST Control Field (C31:C0)**

**Figure 23-76. ADCNST Data Field (D31:D0)**

**Cycles** Two

**Register modified** Register T (implicity)

**Description** ADCNST is an extension of ADM32. ADCNST first checks whether the data field value at the remote address is zero; it then performs different adds and moves on the result. ADCNST is typically used to extend the counter value of PWCNT.

**min\_off** A 25-bit constant value that is added to the data field value if the remote data field is null.

**data** A 25-bit value that is always added to the remote data field.  
Default: 0.

**hr\_data** Seven least significant bits of the data addition to the remote data field.  
Default: 0.

Figure 23-77 and Figure 23-78 illustrate the behavior of ADCNST if the remote data field is or is not zero.

**Figure 23-77. ADCNST Operation If Remote Data Field[31:7] Is Not Zero**

**Figure 23-78. ADCNST Operation if Remote Data Field [31:7] Is Zero**

## Execution

```

If (Remote Data Field Value [31:7] != 0)
    Remote Data Field = Immediate Data Field + Remote Data Field;
else
    Remote Data Field = Immediate Data Field + min. offset(bits C24:C0);

Jump to Next Program Address;

```

### 23.5.3.4 ADC, ADD, AND, OR, SBB, SUB, XOR

**Syntax**

```

ADC | ADD | AND | OR | SBB | SUB | XOR {
src1 = { ZERO | IMM | A | B | R | S | T | ONES | REM | REMP }
src2 = { ZERO | IMM | A | B | R | S | T | ONES }
dest = { NONE | IMM | A | B | R | S | T }
[rdest = { NONE | REM | REMP }]
[brk={OFF | ON}]
[next={label | 9-bit unsigned integer}]
[remote={label | 9-bit unsigned integer}]
[control={OFF | ON}]
[init={OFF | ON}]
[smode = {LSL | CSL | LSR | CSR | RR | CRR | ASR }]
[scount = {5 bit unsigned integer}]
[data={25-bit unsigned integer}]
[hr_data={7-bit unsigned integer}]
}

```

**Figure 23-80. ADC, ADD, AND, OR, SBB, SUB, XOR Control Field (C31:C0)**

**Figure 23-81. ADC, ADD, AND, OR, SBB, SUB, XOR Data Field (D31:D0)**

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Cycles</b>            | One to three cycles, depending on operands selected. (See <a href="#">Table 23-56</a> )                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Register modified</b> | Selected register (A, B, R, S, T, or NONE)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b>       | This instruction performs the specified 32-bit arithmetic or logical operation on operands src1 and src2, followed by an optional shift/rotate step. The result of this operation is then stored to either an N2HET register or the immediate data field of the instruction. In addition, the same result may be stored in a remote data field or the least significant bits of a remote instruction program field (P[8:0]). Bits P[8:0] of the program field are used by most instructions formats to hold the remote address that the instruction operates on, so the ability to update this field programatically makes it easier to write subroutines that operate on different data sets. |

The Sub-Opcode field C[25:3] determines which type of operation (ADD, ADC, AND, OR, SBB, SUB, XOR) is executed by the instruction. A list of these operations and the corresponding Sub-Opcode encoding can be found in [Table 23-52](#).

All arithmetic is performed using 32-bit integer math. However, source and destination operands vary in width and can be 9 bits (REMP), 25 bits (A, B) or 32 bits (R,S,T, IMM, REM). Source operands REM, A,B are extended to 32-bits before being operated on. Also the result of the computation needs to be truncated before being written back to REM, A, or B when these are selected as destination operands. [Table 23-53](#) provides a list of source operand options, how they are expanded to 32-bit integers (if applicable) and the control field encoding to select the option for src1 and src2 operands.

[Table 23-54](#) provides a similar list of destination operands and their encodings. Up to two destination operands may be selected for each instruction, a register/immediate destination and a remote destination may be selected simultaneously. Truncation is performed independently for each destination operand as appropriate to its size.

An optional shift step following the arithmetic or logical operation may be selected through the smode and scout operands. The shift or rotate type is selected by the smode field; [Table 23-55](#) illustrates the options that are available for smode. The number of bits shifted is determined by the scout operand.

**Table 23-52. Arithmetic / Bitwise Logic Sub-Opcodes**

| Instruction | Description                | Operation                | Sub-Opcode     |
|-------------|----------------------------|--------------------------|----------------|
| ADC         | Add with Carry             | result = src1 + src2 + C | C[25:23] = 011 |
| ADD         | Add                        | result = src1 + src2     | C[25:23] = 001 |
| AND         | Bitwise Logic And          | result = src1 & src2     | C[25:23] = 010 |
| OR          | Bitwise Logic Or           | result = src1   src2     | C[25:23] = 100 |
| SBB         | Subtract with Borrow       | result = src1 - src2 - C | C[25:23] = 110 |
| SUB         | Subtract                   | result = src1 - src2     | C[25:23] = 101 |
| XOR         | Bitwise Logic Exclusive Or | result = src1 ^ src2     | C[25:23] = 111 |

**Table 23-53. Source Operand Choices**

| Source Operand | 32-bit value       | Address                     | src1            | src2           |
|----------------|--------------------|-----------------------------|-----------------|----------------|
| A              | {A[24:0], 0x00}    | n/a                         | C[22:19] = 0010 | C[18:16] = 010 |
| B              | {B[24:0], 0x00}    | n/a                         | C[22:19] = 0011 | C[18:16] = 011 |
| R              | R[31:0]            | n/a                         | C[22:19] = 0100 | C[18:16] = 100 |

### 23.5.3.5 ADM32 (Add Move 32)

**Syntax**

```

ADM32 {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    remote={label | 9-bit unsigned integer}
    [control={OFF | ON}]
    [init={OFF | ON}]
    type={IM&REGTOREG | REM&REGTOREG | IM&REMTOREG |
    IM&REGTOREM}
    reg={A | B | R | S | T }
    data={25-bit unsigned integer}
    [hr_data={7-bit unsigned integer}]
}

```

**Figure 23-82. ADM32 Program Field (P31:P0)**

**Figure 23-83. ADM32 Control Field (C31:C0)**

**Figure 23-84. ADM32 Data Field (D31:D0)**

**Cycles** One or two cycles (see [Table 23-57](#))

**Register modified** Selected register (A, B, R, S, or T)

**Description** This instruction modifies the selected ALU register or data field values at the remote address depending on the move type. The modified value results from adding the immediate or remote data field to the ALU register or the remote data field, depending on the move type. Table description shows the C2 and C1 bit encoding for determining which register is selected.

**init** (Optional) Determines whether or not system flags are initialized. A value of ON reinitializes the following system flags to these states:

- Acceleration flag (ACF) = 0
- Deceleration flag (DCF) = 1
- Gap flag (GPF) = 0

**type**

New angle flag (NAF) = 0  
 A value of OFF results in no change to the system flags.  
 Default: OFF  
 Specifies the move type to be executed.

**Table 23-57. Move Types for ADM32**

| Type         | C4 | C3 | Add                                       | Destination(s)            | Cycles |
|--------------|----|----|-------------------------------------------|---------------------------|--------|
| IM&REGTOREG  | 0  | 0  | Imm. data field + Reg. A, B, R, S, or T   | Register A, B, R, S, or T | 1      |
| REM&REGTOREG | 0  | 1  | Remote data field + Reg. A, B, R, S, or T | Register A, B, R, S, or T | 2      |
| IM&REMTOREG  | 1  | 0  | Imm. data field + Remote data field       | Register A, B, R, S, or T | 2      |
| IM&REGTOREM  | 1  | 1  | Imm. data field + Reg. A, B, R, S, or T   | Remote data field         | 1      |

If selected register is R, S, or T, the operation is a 32-bit Addition/move. If A or B register is selected, it is limited to 25-bit operation since A and B only support 25-bit.

**data**

Specifies the 25-bit integer value for the immediate data field.

**hr\_data**

Specifies the 7 least significant bits of the immediate data field.  
 Default: 0.

### Execution

```

switch (C4:C3)
{
    case 00:
        Selected register = Selected register + Immediate Data Field;
    case 01:
        Selected register = Selected register + Remote Data Field;
    case 10:
        Selected register = Immediate Data Field + Remote Data Field;
    case 11:
        Remote Data Field = Selected register + Immediate Data Field;
}

If (Init Flag == 1)
{
    ACF = 0;
    DCF = 1;
    GPF = 0;
    NAF = 0;
}
else
    All flags remain unchanged;

Jump to Next Program Address;
  
```

Figure 23-85 and Figure 23-86 illustrate the ADM32 operation for various cases.

**Figure 23-86. ADM32 Add and Move Operation for REM&REGTOREG (Case 01)**

### 23.5.3.6 APCNT (Angle Period Count)

**Syntax**

```

APCNT {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [reqnum={3-bit unsigned integer}]
    [request={NOREQ | GENREQ | QUIET}]
    [irq={OFF | ON}]
    type={FALL2FALL | RISE2RISE}
    [control={OFF | ON}]
    prv={OFF | ON}}
    period={25-bit unsigned integer}
    data={25-bit unsigned integer}
}
    
```

**Figure 23-87. APCNT Program Field (P31:P0)**

**Figure 23-88. APCNT Control Field (C31:C0)**

**Figure 23-89. APCNT Data Field (D31:D0)**

#### Cycles

One or two cycles

- Cycle 1: edge detected (normal operation)
  - Cycle 2: edge detected and GPF = 1 and underflow condition is true
- One cycle (normal operation) two cycles (edge detected)

#### Register modified

Register A and T (implicitly)

#### Description

This instruction is used before SCNT and ACNT to generate an angle-referenced time base synchronized to an external signal (that is, a toothed wheel signal). It is assumed that the pin and edge selections are the same for APCNT and ACNT.

APCNT is restricted to pin HET[2]. The toothed wheel must then be connected to pin HET[2].

APCNT uses the gap flag (GPF) defined by ACNT to start or stop captures in the period count field [C24:C0]. When GPF = 1, the previous period value is held in the control field and in register T. When GPF = 0, the current period value is captured in the control field and in register T.

APCNT uses the step width flags (SWF0 and SWF1) defined by SCNT to detect period durations shorter than one step, and then disables capture. The edge select encoding is shown in [Table 23-58](#).

|             |                                                                                                                              |
|-------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>irq</b>  | ON generates an interrupt when the edge state is satisfied. OFF prevents an interrupt from being generated.<br>Default: OFF. |
| <b>type</b> | Specifies the edge type that triggers the instruction.<br>Default: Fall2Fall.                                                |

**Table 23-58. Edge Select Encoding for APCNT**

| type      | P7 | P6 | Selected Condition |
|-----------|----|----|--------------------|
| Fall2Fall | 1  | 0  | Falling edge       |
| Rise2Rise | 1  | 1  | Rising edge        |

|               |                                                                 |
|---------------|-----------------------------------------------------------------|
| <b>period</b> | Contains the 25-bit count value from the previous APCNT period. |
| <b>data</b>   | 25-bit value serving as a counter.<br>Default: 0.               |

## Execution

```

Z = 0;

If (Data field register != 1FFFFFFh)
{
    Register A = Data field register + 1;
    Data field register = Data field register + 1;
}
elseif (specified edge not detected on HET[2])
{
    Register A = 1FFFFFFh;
    APCNT Ovflw flag = 1;
}

If (specified edge detected on HET[2])
{
    Z = 1;

    If (Data field register == 1FFFFFFh)
    {
        Register A = 1FFFFFFh;
        Register T = 1FFFFFFh; Period count = 1FFFFFFh;
        Period count = 1FFFFFFh;
    }
    elseif (GPF == 0 AND Data Field register >= Step width)
    {
        Register A = Data field register + 1;
        Register T = Register A;
        Period count = Register T;

        If (Interrupt Enable == 1)
            HETFLG[n] = 1; /* n depends on address */
        If ([C28:C27] == 01)
            Generate request on request line [P25:P23];
        If ([C28:C27] == 11)
            Generate quiet request on request line [P25:P23];
    }
}

```

```

    }

    If (GPF == 1)
        Register T = Period count;
    If (Data Field register < Step width)
    {
        Register T = Period count;
        APCNT Undflw flag = 1;
        Period Count = 000000h;
    }

    Data field register = 000000h;
}
else
{
    Register T = Period count;
}

Prv bit = Current Lx value of HET[2] pin;

Jump to Next Program Address;

```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

### 23.5.3.7 BR (Branch)

#### Syntax

```
BR {
  [brk={OFF | ON}]
  [next={label | 9-bit unsigned integer}]
  [reqnum={3-bit unsigned integer}]
  [request={NOREQ | GENREQ | QUIET}]
  [control={OFF | ON}]
  [prv={OFF | ON}]
  cond_addr={label | 9-bit unsigned integer}
  [pin= {pin number}]
  event={NOCOND | FALL | RISE | BOTH | ZERO | NAF | LOW | HIGH | C | NC
  | EQ | Z | NE | NZ | N | PZ | V | NV | ZN | P | GE | LT | GT | LE | LO | HS }
  [irq={OFF | ON}]
}
```

**Figure 23-90. BR Program Field (P31:P0)**

**Figure 23-91. BR Control Field (C31:C0)**

**Figure 23-92. BR Data Field (D31:D0)**

#### Cycles

One

#### Register modified

None

#### Description

This instruction executes a jump to the conditional address [C21:C13] on a pin or a flag condition, and can be used with all pins.

[Table 23-59](#) provides the branch condition encoding.

#### event

Specifies the event that triggers a jump to the indexed program address.

Default: FALL

**irq**

ON generates an interrupt when the event occurs that triggers the jump. If irq is set to OFF, no interrupt is generated.

Default: OFF.

**Table 23-59. Branch Condition Encoding for BR**

| event  | C7 | C6 | C5 | C4 | C3 | Branch Condition                             |
|--------|----|----|----|----|----|----------------------------------------------|
| NOCOND | 0  | 0  | 0  | 0  | 0  | Always                                       |
| FALL   | 0  | 0  | 1  | 0  | 0  | On falling edge on the selected pin          |
| RISE   | 0  | 1  | 0  | 0  | 0  | On rising edge on selected pin               |
| BOTH   | 0  | 1  | 1  | 0  | 0  | On rising or falling edge on selected pin    |
| ZERO   | 1  | 0  | 0  | 0  | 0  | If Zero flag is set                          |
| NAF    | 1  | 0  | 1  | 0  | 0  | If NAF_global flag is set                    |
| LOW    | 1  | 1  | 0  | 0  | 0  | On LOW level on selected pin                 |
| HIGH   | 1  | 1  | 1  | 0  | 0  | On HIGH level on selected pin                |
| C      | 0  | 0  | 0  | 0  | 1  | Carry Set: C==1                              |
| NC     | 0  | 0  | 0  | 1  | 1  | Carry Not Set: C==0                          |
| EQ, Z  | 0  | 0  | 1  | 0  | 1  | Equal or Zero: Z==1                          |
| NE, NZ | 0  | 0  | 1  | 1  | 1  | Not Equal or Not Zero: Z==0                  |
| N      | 0  | 1  | 0  | 0  | 1  | Negative: N==1                               |
| PZ     | 0  | 0  | 1  | 1  | 1  | Positive or Zero: N==0                       |
| V      | 0  | 1  | 1  | 0  | 1  | Overflow: V==1                               |
| NV     | 0  | 1  | 1  | 1  | 1  | No Overflow: V==0                            |
| ZN     | 1  | 0  | 0  | 0  | 1  | Zero or Negative: (Z OR N) == 1              |
| P      | 1  | 0  | 0  | 1  | 1  | Positive: (Z OR N) == 0                      |

| L      | 1  | 0  | 1  | 0  | 1  | Signed Less Than (N XOR V) == 1              |
| G      | 1  | 1  | 0  | 1  | 1  | Signed Greater Than (Z OR (N XOR V)) == 0    |
| LE     | 1  | 1  | 0  | 0  | 1  | Signed Less Than (Z OR (N XOR V)) == 1       |
| LO     | 1  | 1  | 1  | 1  | 1  | Unsigned Less Than: (C OR Z) == 0            |
| HS     | 1  | 1  | 1  | 0  | 1  | Unsigned Higher or Same (C OR Z) == 1        |

## Execution

```

If (Condition is true)
{
    If (Interrupt Enable == 1) HETFLG[n] = 1;          /* n depends on address */
    If ([C28:C27] == 01) Generate request on request line [P25:P23];
    If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];
    Jump to Conditional Address;
}
else
{
    Jump to Next Program Address;
}

```

Prv bit = Current Lx value of selected pin; (Always Executed)

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

### 23.5.3.8 CNT (Count)

**Syntax**

```

CNT {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [reqnum={3-bit unsigned integer}]
    [request={NOREQ | GENREQ | QUIET}]
    [angle_count={OFF | ON}]
    [reg={A | B | T | NONE}]
    [comp = {EQ | GE}]
    [irq={OFF | ON}]
    [control={OFF | ON}]
    max={25-bit unsigned integer}
    [data={25-bit unsigned integer}]
}

```

**Figure 23-93. CNT Program Field (P31:P0)**

**Figure 23-95. CNT Data Field (D31:D0)**

|      |   |          |   |
|------|---|----------|---|
| 31   | 7 | 6        | 0 |
| Data |   | Reserved |   |
| 25   | 7 |          |   |

**Cycles** One or two  
One cycle (time mode), two cycles (angle mode)

**Register modified** Selected register (A, B or T)

**Description** This instruction defines a virtual timer. The counter value stored in the data field [D31:7] is incremented unconditionally on each resolution when in time mode (angle count bit [P8] = 0). When the count reaches the maximum count specified in the control field, the counter is reset. It takes one cycle in this mode.

In angle mode (angle count bit [P8] = 1), CNT needs data from the software angle generator (SWAG). When in angle count mode the angle increment value will be 0 or 1. It takes two cycles in this mode.

|                    |                                                                                                                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>angle_count</b> | Specifies when the counter is incremented. A value of ON causes the counter value to be incremented only if the new angle flag is set (NAF_global = 1). A value of OFF increments the counter each time the CNT instruction is executed.<br>Default value for this field is OFF. |
| <b>comp</b>        | When set to EQ the counter is reset, when it is equal to the maximum count.<br>When set to GE the counter is reset, when it is greater or equal to the maximum count.<br>Default: GE.                                                                                            |
| <b>irq</b>         | ON generates an interrupt when the counter overflows to zero. The interrupt is not generated until the data field is reset to zero. If irq is set to OFF, no interrupt is generated.<br>Default: OFF.                                                                            |
| <b>max</b>         | Specifies the 25-bit integer value that defines the maximum count value allowed in the data field. When the count in the data field is equal to max, the data field is reset to 0 and the Z system flag is set to 1.                                                             |
| <b>data</b>        | Specifies the 25-bit integer value serving as a counter.<br>Default: 0.                                                                                                                                                                                                          |

## Execution

```

Z = 0;

If (Angle Count (bit P8 == 1))
{
    If (NAF_global == 0)
    {
        Selected register = immediate data field;
        Jump to Next Program Address;
    }
    else
    {
        If ((Immediate Data Field + Angle Increment) >= Max count)
        {
            Z = 1;
            Selected register = ((Immediate Data Field + Angle Inc.) - Max count);
            Immediate Data Field = ((Immediate Data Field + Angle Inc.) - Max count);

            If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */
            If ([C28:C27] == 01) Generate request on request line [P25:P23];
            If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];
        }
        else
        {
            Selected register = Immediate Data Field + Angle Increment;
            Immediate Data Field = Immediate Data Field + Angle Increment;
        }
    }
}

else if(Time mode (bit P8 == 0))
{
    If [(P5==0) AND (Immediate Data Field == Max count)]
    OR [(P5==1) AND (Immediate Data Field >= Max count)]
    {
        Z = 1;
    }
}

```

```
Selected register = 00000;  
Immediate Data Field = 00000;  
  
If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */  
If ([C28:C27] == 01) Generate request on request line [P25:P23];  
If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];  
}  
else  
{  
    Selected register = Immediate Data Field + 1;  
    Immediate Data Field = Immediate Data Field + 1;  
}  
}  
  
Jump to Next Program Address;
```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

### 23.5.3.9 DADM64 (Data Add Move)

#### Syntax

```
DADM64 {
  [brk={OFF | ON}]
  [next={label | 9-bit unsigned integer}]
  remote={label | 9-bit unsigned integer}
  [request={NOREQ | GENREQ | QUIET}]
  [control={OFF | ON}]
  [en_pin_action={OFF | ON}]
  [cond_addr={label | 9-bit unsigned integer}]
  [pin={pin number}]
  comp_mode={ECMP | SCMP | MCMP1 | MCMP2}
  [action={CLEAR | SET | PULSELO | PULSEHI}]
  [reg={A | B | R | S | T | NONE}]
  [irq={OFF | ON}]
  [data={25-bit unsigned integer}]
  [hr_data= {7-bit unsigned integer}]
}
```

-or-

#### Syntax

```
DADM64 {
  [brk={OFF | ON}]
  [next={label | 9-bit unsigned integer}]
  remote={label | 9-bit unsigned integer}
  cntl_val={29-bit unsigned integer}
  data={25-bit unsigned integer}
  [hr_data= {7-bit unsigned integer}]
}
```

| <b>Cycles</b>            | Two                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Register modified</b> | Register T (implicitly)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>       | <p>This instruction modifies the data field and the control field at the remote address. The remote data field value is not just replaced, but is added with the DADM64 data field.</p> <p>DADM64 has two distinct syntaxes. In the first syntax, bit values may be set by assigning a value to each of the control fields. This syntax is convenient for modifying control fields that are arranged similarly to the format of the DADM64 control field. A second syntax, in which the entire 29-bit control field is specified by the cntl_val field, is convenient when the remote control field is dissimilar to the DADM64 control field. Either syntax may be used, but you must use one or the other but not a combination of syntaxes.</p> |

Figure 23-99 shows the DADM64 add and move operation.

**Figure 23-99. DADM64 Add and Move Operation**

**Table 23-60. DADM64 Control Field Description**

|               |                                                                      |
|---------------|----------------------------------------------------------------------|
| request       | maintains the control field for the remote instruction               |
| control       | maintains the control field for the remote instruction               |
| en_pin_action | maintains the control field for the remote instruction               |
| cond_addr     | maintains the control field for the remote instruction               |
| pin           | maintains the control field for the remote instruction               |
| register      | maintains the control field for the remote instruction               |
| action        | maintains the control field for the remote instruction               |
| irq           | maintains the control field for the remote instruction               |
| data          | Specifies the 25-bit initial value for the data field.               |
| hr_data       | Seven least significant bits of the 32 bit data field.<br>Default: 0 |
| cntl_val      | Specifies the 29 least significant bits of the Control field.        |

## Execution

```
Remote Data Field = Remote Data Field + Immediate Data Field;
Register T = Immediate Data Field;
Remote Control Field = Immediate Control Field;
Jump to Next Program Address;
```

### 23.5.3.10 DJZ (Decrement and Jump if Zero)<sup>†</sup>

#### Syntax

```

DJZ {
[brk={OFF | ON}]
[next={label | 9-bit unsigned integer}]
[reqnum={3-bit unsigned integer}]
[request={NOREQ | GENREQ | QUIET}]
[control={OFF | ON}]
[cond_addr={label | 9-bit unsigned integer}]
[reg={A | B | T | NONE}]
[irq={OFF | ON}]
[data={25-bit unsigned integer}]
}

```

**Figure 23-100. DJZ Program Field (P31:P0)**

**Figure 23-101. DJZ Control Field (C31:C0)**

**Figure 23-102. DJZ Data Field (D31:D0)**

#### Cycles

One

#### Register modified

Selected register (A, B, or T)

<sup>†</sup> DJNZ is also supported syntax. The functionality of the two instruction names is identical.

#### Description

This instruction defines a virtual down counter used for delayed execution of certain instructions (to generate minimum on/off times). When DJZ is executed with counter value not zero, the counter value is decremented. If the counter value is zero, the counter remains zero until it is reloaded with a non-zero value. The program flow can be modified when down counter value is zero by using the conditional address.

|                  |                                                                                                                                                                         |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>cond_addr</b> | This field is not optional for the DJZ instruction.                                                                                                                     |
| <b>irq</b>       | ON generates an interrupt when the data field reaches zero. No interrupt is generated when the bit is OFF.<br>Default: OFF.                                             |
| <b>data</b>      | Specifies the 25-bit integer value used as a counter. This counter is decremented each time the DJZ instruction is executed until the counter reaches 0.<br>Default: 0. |

## Execution

```

If (Data != 0)
{
    Data = Selected register = Data - 1;
    Jump to Next Program Address;
}
else
{
    Selected register = 000000h;

    If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */
    If ([C28:C27] == 01) Generate request on request line [P25:P23];
    If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];

    Jump to conditional Address;
}

```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

### 23.5.3.11 ECMP (Equality Compare)

**Syntax**

```

ECMP {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [reqnum={3-bit unsigned integer}]
    [request={NOREQ | GENREQ | QUIET}]
    [hr_lr={HIGH | LOW}]
    [angle_comp={OFF | ON}]
    [control={OFF | ON}]
    [en_pin_action={OFF | ON}]
    [cond_addr={label | 9-bit unsigned integer}]
    pin={pin number}
    [action={CLEAR | SET | PULSELO | PULSEHI}]
    [reg={A | B | R | S | T | NONE}]
    [irq={OFF | ON}]
    [data={25-bit unsigned integer}]
    [hr_data={7-bit unsigned integer}]
}
    
```

**Figure 23-103. ECMP Program Field (P31:P0)**

**Figure 23-104. ECMP Control Field (C31:C0)**

**Figure 23-105. ECMP Data Field (D31:D0)**

**Cycles** One

**Register modified** Register A, B, R, S or T if selected

**Description** ECMP can use all pins. This instruction compares a 25-bit data value stored in the data field (D31–D7) to the value stored in the selected ALU register (A, B, R, S, or T). Register select encoding can be found in [Section 23.5.2](#).

If R, S, or T registers are selected, and if the 25-bit data field matches, ECMP updates the register with the 32-bit value (D31-D0).

If the hr\_lr bit is cleared, the pin action will occur after a high resolution delay from the next loop resolution clock. If the hr\_lr bit is set, the delay is ignored. This delay is programmed in the data field (D6-D0).

The behavior of the pins is governed by the four action options in bits C4:C3. ECMP uses the zero flag to generate opposite pin action (synchronized to the loop resolution clock).

|                   |                                                                                                                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>angle_comp</b> | Determines if an angle compare is performed. A value of ON causes the comparison to be performed only if the new angle flag is set (NAF = 1). If OFF is specified, the compare is then performed regardless of the state of the new angle flag.<br>Default: OFF. |
| <b>irq</b>        | Specifies whether or not an interrupt is generated. A value of ON sends an interrupt if register and data field values are equivalent. If OFF is selected, no interrupt is generated.<br>Default: OFF.                                                           |
| <b>data</b>       | Specifies the value for the data field. This value is compared with the selected register.                                                                                                                                                                       |
| <b>hr_data</b>    | Specifies the HR delay.<br>Default: 0.                                                                                                                                                                                                                           |

## Execution

```

If (Angle Comp. bit == 0 OR (Angle Comp. bit == 1 AND NAF_global == 1))
{
    If (Selected register value == Immediate data field value)
    {
        If (hr_lr bit == 0)
        {
            If (Enable Pin action == 1)
            {
                Selected Pin = Pin Action AT next loop resolution clock + HR delay;
            }
        }
        else
        {
            If (Enable Pin action == 1)
            {
                Selected Pin = Pin Action AT next loop resolution clock;
            }
        }
    }

    If (Z == 1 AND Opposite action == 1)
    {
        If (Enable Pin action == 1)
        {
            Selected Pin = opposite Pin Action AT next loop resolution clock;
        }
    }

    If (Interrupt Enable == 1) HETFLG[n] = 1;          /* n depends on address */
    If ([C28:C27] == 01) Generate request on request line [P25:P23];
    If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];

    If (register R is selected) R register = Compare value (32 bit);
    If (register S is selected) S register = Compare value (32 bit);

```

```

        If (register T is selected) T register = Compare value (32 bit);

        Jump to Conditional Address;
    }
}
elseif (Z == 1 AND Opposite action == 1)
{
    If (Enable Pin action == 1)
    {
        Selected Pin = opposite Pin Action AT next loop resolution clock;
    }
    Jump to Next Program Address;
}
else // Angle Comp. bit == 1 AND NAF_global == 0
{
    Jump to Next Program Address;
}

```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

### 23.5.3.12 ECNT (Event Count)

**Syntax**

```

ECNT {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [reqnum={3-bit unsigned integer}]
    [request={NOREQ | GENREQ | QUIET}]
    [control={OFF | ON}]
    [prv={OFF | ON}]
    [cond_addr={label | 9-bit unsigned integer}]
    pin={pin number}
    event={NAF | FALL | RISE | BOTH | ACCUHIGH | ACCULOW}
    [reg={A | B | R | S | T | NONE}]
    [irq={OFF | ON}]
    [data={25-bit unsigned integer}]
}

```

| <b>Cycles</b>            | One cycle                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Register modified</b> | Selected Register (A, B, R, S, T or none)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>       | <p>This instruction defines a specialized 25-bit virtual counter used as an event counter or pulse accumulator (see <a href="#">Table 23-61</a>). The counter value is stored in the data field [D31:D7] and the selected register. If one of the 32-bit registers (R,S,T) is selected, the 25 bit count value is stored left justified in the register with zeros in the seven least significant bits.</p> <p>When an event count condition is specified, the counter value is incremented on a pin edge condition or on the NAF condition (NAF is defined in ACNT). This instruction can be used with all pins.</p> |

**event** The event that triggers the counter.

**Table 23-61. Event Encoding Format for ECNT**

| event    | C6 | C5 | C4 | Count Conditions                        | Mode               | Int. Available |
|----------|----|----|----|-----------------------------------------|--------------------|----------------|
| NAF      | 0  | 0  | 0  | NAF flag is Set                         | Angle counter      | Y              |
| FALL     | 0  | 0  | 1  | Falling edge on selected pin            | Event counter      | Y              |
| RISE     | 0  | 1  | 0  | Rising edge on selected pin             | Event counter      | Y              |
| BOTH     | 0  | 1  | 1  | Rising and Falling edge on selected pin | Event counter      | Y              |
| ACCUHIGH | 1  | 0  | -  | while pin is high level                 | Pulse accumulation | N              |
| ACCULOW  | 1  | 1  | -  | while pin is low level                  | Pulse accumulation | N              |

**irq** ON generates an interrupt when event in counter mode occurs. No interrupt is generated with OFF.  
Default: OFF.

**data** 25-bit integer value serving as a counter.  
Default: 0.

## Execution

```

If (event occurs)
{
    If (Register A or B Selected) {
        Selected register = Immediate Data Field + 1;
    }

    If (Register R, S or T Selected)
    {
        Selected register[31:7] = Immediate Data Field + 1;
        Selected register[6:0] = 0;
    }

    Immediate Data Field = Immediate Data Field + 1;

    If (Interrupt Enable == 1) HETFLG[n] = 1; /* n depends on address */
    If ([C28:C27] == 01) Generate request on line [P25:P23];
    If ([C28:C27] == 11) Generate quiet request on line [P25:P23];

    Jump to Conditional Address;
}
else
{
    Jump to Next Program Address;
}

Prv bit = Current Logic (Lx) value of selected pin; (Always executed)

```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

### 23.5.3.13 MCMP (Magnitude Compare)

**Syntax**

```

MCMP {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [reqnum={3-bit unsigned integer}]
    [request={NOREQ | GENREQ | QUIET}]
    [hr_lr={LOW | HIGH}]
    [angle_comp={OFF | ON}]
    [savesub={OFF | ON}]
    [control={OFF | ON}]
    [en_pin_action={OFF | ON}]
    [cond_addr={label | 9-bit unsigned integer}]
    pin={pin number}
    order={REG_GE_DATA | DATA_GE_REG}
    [action={CLEAR | SET | PULSELO | PULSEHI}]
    reg={A | B | R | S | T | NONE}
    [irq={OFF | ON}]
    [data={25-bit unsigned integer}]
    [hr_data={7-bit unsigned integer}]
}

```

| <b>Register modified</b> | T (if save sub bit P[5] is set)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b>       | <p>This instruction compares the magnitude of the 25-bit data value stored in the data field (D31-D7) and the 25-bit value stored in the selected ALU register (A, B, R, S, or T).</p> <p>If the hr_lr bit is reset, pin action will occur after a delay from the next loop resolution clock. If the hr_lr bit is set, the delay is ignored. This delay is programmed in the data field (D6-D0).</p> <p>When the data value matches, an output pin can be set or reset according to the pin action bit (C[4]). The pin will not change states if the enable pin action bit (C[22]) is reset.</p> <p>MCMP uses the zero flag set to generate opposite pin action (synchronized to the loop resolution clock). The save sub bit (P[5]) provides the option to save the result of a subtraction into register T.</p> |

---

**NOTE: The Difference Between Compare Values**

The difference between the two data values must not exceed  $(2^{24}) - 1$ .

---

|                   |                                                                                                                                                                                                                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>angle_comp</b> | <p>Determines whether or not an angle compare is performed. A value of ON causes the comparison to be performed only if the new angle flag is set (NAF = 1). If OFF is specified, the compare is then performed regardless of the state of the new angle flag.</p> <p>Default: OFF.</p> |
| <b>savesub</b>    | <p>When set, the comparison result is saved into the T register (upper 25 bits).</p> <p>Default: OFF.</p>                                                                                                                                                                               |
| <b>order</b>      | Specifies the order of the operands for the comparison.                                                                                                                                                                                                                                 |

**Table 23-62. Magnitude Compare Order for MCMP**

| Order       | C5 | Description                                                                               |
|-------------|----|-------------------------------------------------------------------------------------------|
| REG_GE_DATA | 0  | Evaluates to true if the register value is greater than or equal to the data field value. |
| DATA_GE_REG | 1  | Evaluates to true if the data field value is greater than or equal to the register value. |

|                |                                                                                                                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>irq</b>     | Specifies whether or not an interrupt is generated. A value of ON sends an interrupt if the compare match occurs according to the order selected. If OFF is selected, no interrupt is generated. |
| <b>data</b>    | Specifies the value for the data field. This value is compared with the selected register.                                                                                                       |
| <b>hr_data</b> | HR delay. The default value for an unspecified bit is 0.                                                                                                                                         |

## Execution

```

If (Angle Compare P[7] == 0 OR (P[7] == 1 AND NAF_global == 1))
{
    If( (Order C[5] == 1) AND (Data[31:7]- Selected register[31:7]) >= 0))
    OR ( (Order C[5] == 0) AND Selected register[31:7] - Data[31:7]) >= 0))
    {
        If (Order C[5] == 1 AND Save subtract P[5] == 1)
        {
            Register T[31:7] = Data[31:7] - Selected register[31:7];
            Register T[6:0] = 0;
        }

        If (Order C[5] == 0 AND Save subtract P[5] == 1)
        {
            Register T[31:7] = Selected register[31:7] - Data[31:7];
            Register T[6:0] = 0;
        }

        If (Enable Pin Action C[22] == 1)
        {
            If (hr_lr P[8] = 0) {
                Schedule Action on Selected Pin C[12:8] at start of next loop
                + HR Delay D[6:0];
            }
            else
            {
                Schedule Pin Action on Selected Pin C[12:8] at start of next loop;
            }
        }

        If (Interrupt Enable == 1) HETFLG[n] = 1;          /* n depends on address */
        If ([C28:C27] == 01) Generate request on request line [P25:P23];
        If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];

        Jump to Conditional Address;
    }
    else if (Z == 1 AND Opposite Action C[3] == 1 )
    {
        If (Enable Pin Action C[22] == 1)
        {
            Schedule Opposite Pin Action on Selected Pin C[12:8] at start of next loop;
        }

        Jump to Next Program Address;
    }
    else
        Jump to Next Program Address;
}
else // Angle Comp. bit == 1 AND NAF_global == 0
    Jump to Next Program Address;

```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

### 23.5.3.14 MOV32 (MOVE 32)

**Syntax**

```
MOV32 {
[brk={OFF | ON}]
[next={label | 9-bit unsigned integer}]
[remote={label | 9-bit unsigned integer}]
[control={OFF | ON}]
[z_cond={OFF | ON}]
[init={OFF | ON}] ON}}
type={IMTOREG | IMTOREG&REM | REGTOREM | REMTOREG}
[reg={A | B | R | S | T | NONE}]
[data={25-bit unsigned integer}]
[hr_data={7-bit unsigned integer}]
}
```

**Figure 23-112. MOV32 Program Field (P31:P0)**

**Figure 23-113. MOV32 Control Field (C31:C0)**

**Figure 23-114. MOV32 Data Field (D31:D0)**

**Cycles** One or two cycles

**Register modified** Selected register (A, B, R, S, or T)

**Description** MOV32 replaces the selected ALU register and/or the data field values at the remote address location depending on the move type.  
[Figure 23-115](#) through [Figure 23-118](#) illustrate these operations. If *no register* is selected, the move is not executed, except for configuration C4:C3 = 01, where the remote data field is written with the immediate data field value.

|               |                                                                                                                                                                                                                                                                                                                        |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>remote</b> | Determines the location of the remote address.<br>Default: Current instruction + 1.                                                                                                                                                                                                                                    |
| <b>z_cond</b> | When set to OFF the MOV32 performs the move operation specified by the move type whenever it is executed (independent on the state of the Z-Flag).<br>When set to ON the MOV32 performs the move operation specified by the move type only when the Z-Flag is set.                                                     |
| <b>init</b>   | (Optional) Determines whether or not system flags are initialized. A value of ON reinitializes the following system flags to these states:<br>Acceleration flag (ACF) = 0<br>Deceleration flag (DCF) = 1<br>Gap flag (GPF) = 0<br>New angle flag (NAF) = 0<br>A value of OFF results in no change to the system flags. |
| <b>type</b>   | Specifies the move type to be executed.                                                                                                                                                                                                                                                                                |

**Table 23-63. Move Type Encoding Selection**

| Move Type   | C4 | C3 | Source               | Destination(s)                          | Cycles |
|-------------|----|----|----------------------|-----------------------------------------|--------|
| IMTOREG     | 0  | 0  | Immediate data field | Register A, B, or T                     | 1      |
| IMTOREG&REM | 0  | 1  | Immediate data field | Remote data field & register A, B, or T | 1      |
| REGTOREM    | 1  | 0  | Register A, B, or T  | Remote data field                       | 1      |
| REMTOREG    | 1  | 1  | Remote data field    | Register A, B, or T                     | 2      |

**Figure 23-115. MOV32 Move Operation for IMTOREG (Case 00)**

25/32-bit move

|                |                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>reg</b>     | Specifies which register (A, B, T, or NONE) is involved in the move. A register (A, B, or T) must be specified for every move type except IMTOREG&REM. If <i>NONE</i> is used with move type IMTOREG&REM, the MOV32 executes a move from the immediate data field to the remote data field. If <i>NONE</i> is used with any other move type, no move is executed. |
| <b>data</b>    | Specifies a 25-bit integer value to be written to the remote data field or selected register.                                                                                                                                                                                                                                                                     |
| <b>hr_data</b> | (Optional) HR delay. The default value for an unspecified bit is 0.                                                                                                                                                                                                                                                                                               |

### 23.5.3.15 MOV64 (Data Move)

#### Syntax

```
MOV64 {
[brk={OFF | ON}]
[next={label | 9-bit unsigned integer}]
[remote={label | 9-bit unsigned integer}]
[request={NOREQ | GENREQ | QUIET}]
[control={OFF | ON}]
[en_pin_action={OFF | ON}]
[cond_addr={label | 9-bit unsigned integer}]
[pin={pin number}]
comp_mode={ECMP | SCMP | MCMP1 | MCMP2}
[action={CLEAR | SET | PULSELO | PULSEHI}]
[reg={A | B | R | S | T | NONE}]
[irq={OFF | ON}]
[data={25-bit unsigned integer}]
[hr_data= {7-bit unsigned integer}]
}
```

-or-

#### Syntax

```
MOV64 {
[brk={OFF | ON}]
[next={label | 9-bit unsigned integer}]
[remote={label | 9-bit unsigned integer}]
cntl_val={29-bit unsigned integer}
[data={25-bit unsigned integer}]
[hr_data= {7-bit unsigned integer}]
}
```

**Figure 23-121. MOV64 Data Field (D31:D0)**

**Cycles**                      One

**Register modified**      None

**Description**              This instruction modifies the data field and the control field at the remote address.

MOV64 has two distinct syntaxes. In the first syntax, bit values may be set by assigning a value to each of the control fields. This syntax is convenient for modifying control fields that are arranged similarly to the format of the MOV64 control field. A second syntax, in which the entire 29-bit control field is specified by the `cntl_val` field, is convenient when the remote control field is dissimilar to the MOV64 control field. Either syntax may be used, but you must use one or the other but not a combination of syntaxes. See [Figure 23-122](#).

**Figure 23-122. MOV64 Move Operation**

**Table 23-64. MOV64 Control Field Descriptions**

|                   |                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------|
| request           | Maintains the control field for the remote instruction.                                           |
| control           | Maintains the control field for the remote instruction.                                           |
| en_pin_action     | Maintains the control field for the remote instruction.                                           |
| cond_addr         | Maintains the control field for the remote instruction.                                           |
| pin               | Maintains the control field for the remote instruction.                                           |
| register, ext reg | Maintains the control field for the remote instruction.                                           |
| comp_mode         | Selects the comparison mode type to be used by the remote instruction.                            |
| action            | Maintains the control field for the remote instruction.                                           |
| irq               | Maintains the control field for the remote instruction.                                           |
| data              | Specifies the 25-bit initial count value for the data field. If omitted, the field defaults to 0. |
| hr_data           | (Optional) HR delay. The default value for an unspecified bit is 0.                               |

**Table 23-65. Comparison Type Encoding Format**

| comp_mode | C[6] | C[5] | MCMP order  |
|-----------|------|------|-------------|
| ECMP      | 0    | 0    |             |
| SCMP      | 0    | 1    |             |
| MCMP1     | 1    | 0    | REG_GE_DATA |
| MCMP2     | 1    | 1    | DATA_GE_REG |

## Execution

```
Remote Data Field = Immediate Data Field;
Remote Control Field = Immediate control Field;
Jump to Next Program Address;
```

### 23.5.3.16 PCNT (Period/Pulse Count)

**Syntax**

```
PCNT {
    [hr_lr={HIGH | LOW}]
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [reqnum={3-bit unsigned integer}]
    [request={NOREQ | GENREQ | QUIET}]
    [irq={OFF | ON}]
    type={FALL2RISE | RISE2FALL | FALL2FALL | RISE2RISE}
    pin={pin number}
    [control={OFF | ON}]
    [prv={OFF | ON}]
    [period={25-bit unsigned integer}]
    [data={25-bit unsigned integer}]
    [hr_data= {7-bit unsigned integer}]
}
```

**Figure 23-123. PCNT Program Field (P31:P0)**

**Figure 23-124. PCNT Control Field (C31:C0)**

**Figure 23-125. PCNT Data Field (D31:D0)**

**Cycles** One

**Register modified** Register A

**Description** This instruction detects the edges of the external signal at loop start and measures its period or pulse duration. The counter value stored in the control field C[24:0] and in the register A is incremented each N2HET loop. PCNT uses the HR structure on the pin to measure an HR period/pulse count value.

**hr\_lr** (Optional) Specifies whether the PCNT instruction captures the HR delay into the HR data field on the selected edge condition. If hr\_lr is 0 (HIGH) then PCNT captures the HR delay. if hr\_lr is 1 (LOW) then PCNT only captures at loop resolution.

|             |                                                                                                                                                                              |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>irq</b>  | (Optional) Specifies whether or not an interrupt is generated. A value of ON sends an interrupt when a new value is captured. If OFF is selected, no interrupt is generated. |
| <b>type</b> | (Optional) Determines the type of counter that is implemented.                                                                                                               |

**Table 23-66. Counter Type Encoding Format**

|           | <b>P7</b> | <b>P6</b> | <b>Period/Pulse Select</b>                         | <b>Reset On</b> | <b>Capture On</b> |
|-----------|-----------|-----------|----------------------------------------------------|-----------------|-------------------|
| FALL2RISE | 0         | 0         | Count low pulse duration on selected pin           | Falling edge    | Rising edge       |
| RISE2FALL | 0         | 1         | Count high pulse duration on selected pin          | Rising edge     | Falling edge      |
| FALL2FALL | 1         | 0         | Count period between falling edges on selected pin | Falling edge    | Falling edge      |
| RISE2RISE | 1         | 1         | Count period between rising edges on selected pin  | Rising edge     | Rising edge       |

|                |                                                                                                                                 |
|----------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>period</b>  | Specifies the 25-bit integer value that holds the counter value. The counter value is also stored in register A.<br>Default: 0. |
| <b>data</b>    | 25-bit integer representing the last captured counter value.<br>Default: 0.                                                     |
| <b>hr_data</b> | HR delay.<br>Default: 0.                                                                                                        |

If *period-measure* is selected, PCNT captures the counter value into the period/pulse data field [D31:D7] on the selected edge. The HR structure provides HR capture field [D6:D0]. The counter value [C24:C0] is reset on the same edge. The captured period value is a 32-bit value.

If *pulse-measure* is selected, PCNT captures the counter value into the period/pulse count field [D31:D7] on the selected edge. The HR structure provides HR capture field [D6:D0]. The counter value [C24:C0] is reset on the next opposite edge. The captured pulse value is a 32-bit value.

When the overflow count (all 1's in the counter value) is reached, PCNT stops counting until the next reset edge is detected.

Note: For FALL2FALL/RISE2RISE, the user should always discard the first interrupt/HTU request if interrupt/request are enabled before HET\_ON. For both the types, reset edge and capture edge are the same and the interrupt or HTU request is triggered on capture edge (which is nothing but the reset edge). Once the execution unit is enabled, the first edge generates an interrupt but the value of the counter is of no use as this is not the period between 2 edges. So first edge after turning on N2HET is used mainly for resetting the counter and start the period count.

## Execution

```

Z = 0;

If (Period C[24:0] != 1FF_FFFFh) {
    Period C[24:0] = Period C[24:0] + 1;
}

Register A = Period C[24:0];

If (specified capture edge detected on selected pin)
{
    Z = 1;

    If (Period value != 1FF_FFFFh)

```

```

    {
        HR Capture Value = selected HR counter;
    }
    else
    {
        HR Capture Value = 7Fh;
    }

    If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */
    If ([C28:C27] == 01) Generate request on request line [P25:P23];
    If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];
}

If (specified reset edge detected on selected pin)
{
    Period value = 0000000h;
}

Prv bit = Current Logic (Lx) value of selected pin;

Jump to Next Program Address;

```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

### 23.5.3.17 PWCNT (Pulse Width Count)

**Syntax**

```

PWCNT {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [reqnum={3-bit unsigned integer}]
    [request={NOREQ | GENREQ | QUIET}]
    [hr_lr={HIGH | LOW}]
    [control={OFF | ON}]
    [cond_addr={label | 9-bit unsigned integer}]
    [en_pin_action={OFF | ON}]
    pin = {pin number}
    [action={CLEAR | SET | PULSELO | PULSEHI}]
    [reg={A | B | T | NONE}]
    [irq={OFF | ON}]
    [data={25-bit unsigned integer}]
    [hr_data={7-bit unsigned integer}]
}
    
```

**Figure 23-126. PWCNT Program Field (P31:P0)**

**Figure 23-127. PWCNT Control Field (C31:C0)**

**Figure 23-128. PWCNT Data Field (D31:D0)**

**Cycles** One

**Register modified** Selected register (A, B or T)

**Description** This instruction defines a virtual timer used to generate variable length pulses. The counter value stored in the data field is decremented unconditionally on each timer resolution until it reaches zero, and it then stays at zero until it is reloaded with a non-zero value.

The specified pin action is performed as long as the count after count value is decremented is greater than 0. The opposite pin action is performed when the count after decrement just reaches 0.

If the hr\_lr bit is reset, the opposite pin action will be taken after a HR delay from the next loop resolution clock. If the hr\_lr bit is set, the delay is ignored. This delay is programmed in bits [D6:D0].

|                |                                                                                                                    |
|----------------|--------------------------------------------------------------------------------------------------------------------|
| <b>irq</b>     | ON generates an interrupt when the data field value reaches 0. No interrupt is generated for OFF.<br>Default: OFF. |
| <b>data</b>    | 25-bit integer value serving as a counter.                                                                         |
| <b>hr_data</b> | HR delay.<br>Default: 0.                                                                                           |

## Execution

```

If (Data field value == 0)
{
    Selected register = 0;
    Jump to Next Program Address;
}

If (Data field value > 1)
{
    Selected register = Data field value - 1;
    Data field value = Counter value - 1;

    If (Enable Pin action == 1)
    {
        Selected Pin = Pin Action AT next loop resolution clock;
    }

    Jump to Next Program Address;
}

If (Data field value == 1)
{
    Selected register = 0000000h;
    Data field value = 0000000h;

    If (Opposite action == 1)
    {
        If (hr_lr bit == 0)
        {
            If (Enable Pin action == 1)
            {
                Selected Pin = Opposite level of Pin Action AT next loop resolution clock
                + HR delay;
            }
        }
        else
        {
            If (Enable Pin action == 1)
            {
                Selected Pin = Opposite level of Pin Action AT next loop
                resolution clock;
            }
        }
    }

    If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */
    If ([C28:C27] == 01) Generate request on request line [P25:P23];
}

```

```
        If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];  
    }  
    Jump to Conditional Address  
}
```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

### 23.5.3.18 RADM64 (Register Add Move)

#### Syntax

```
RADM64 {
  [brk={OFF | ON}]
  [next={label | 9-bit unsigned integer}]
  remote={label | 9-bit unsigned integer}
  [request={NOREQ | GENREQ | QUIET}]
  [control={OFF | ON}]
  [en_pin_action={OFF | ON}]
  [cond_addr={label | 9-bit unsigned integer}]
  [pin={pin number}]
  comp_mode={ECMP | SCMP | MCMP1 | MCMP2}
  [action={CLEAR | SET | PULSELO | PULSEHI}]
  [reg={A | B | R | S | T | NONE}]
  [irq={OFF | ON}]
  [data={25-bit unsigned integer}]
  [hr_data= {7-bit unsigned integer}]
}
```

-or-

#### Syntax

```
RADM64 {
  [brk={OFF | ON}]
  [next={label | 9-bit unsigned integer}]
  remote={label | 9-bit unsigned integer}
  cntl_val={29-bit unsigned integer}
  [data={25-bit unsigned integer}]
  [hr_data= {7-bit unsigned integer}]
}
```

|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Cycles</b>            | Normally One Cycle. Two cycles if writing to remote address that is also the next address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Register modified</b> | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b>       | <p>This instruction modifies the data field, the HR data field and the control field at the remote address. The advantage over DADM64 is that It executes one cycle faster. In case the R, S, or T register is selected, the addition is a 32-bit addition. The table description shows the bit encoding for determining which ALU register is selected.</p> <p>RADM64 has two distinct syntaxes. In the first syntax, bit values may be set by assigning a value to each of the control fields. This syntax is convenient for modifying control fields that are arranged similar to the format of the RADM64 control field. A second syntax, in which the entire 29-bit control field is specified by the cntl_val field, is convenient when the remote control field is dissimilar from the RADM64 control field. Either syntax may be used, but you must use one or the other but not a combination of syntaxes. See <a href="#">Figure 23-132</a>.</p> |

**Figure 23-132. RADM64 Add and Move Operation**

**comp\_mode**                      Selects the comparison mode type to be used.

**Table 23-67. Comparison Type Encoding Format**

| comp_mode | C[6] | C[5] | MCMP order  |
|-----------|------|------|-------------|
| ECMP      | 0    | 0    |             |
| SCMP      | 0    | 1    |             |
| MCMP1     | 1    | 0    | REG_GE_DATA |
| MCMP2     | 1    | 1    | DATA_GE_REG |

**Table 23-68. RADM64 Control Field Descriptions**

|               |                                                         |
|---------------|---------------------------------------------------------|
| request       | Maintains the control field for the remote instruction. |
| Control       | Maintains the control field for the remote instruction. |
| en_pin_action | Maintains the control field for the remote instruction. |
| cond_addr     | Maintains the control field for the remote instruction. |
| pin           | Maintains the control field for the remote instruction. |
| register      | Maintains the control field for the remote instruction. |
| action        | Maintains the control field for the remote instruction. |

**Table 23-68. RADM64 Control Field Descriptions (continued)**

|          |                                                                                             |
|----------|---------------------------------------------------------------------------------------------|
| irq      | Maintains the control field for the remote instruction.                                     |
| data     | Specifies the 25-bit initial value for the data field. If omitted, the field defaults to 0. |
| hr_data  | Seven least significant bits of the 32-bit data field.<br>Default: 0.                       |
| cntl_val | Specifies the 29 least significant bits of the Control field.                               |

### Execution

Remote Data Field = Selected register + Immediate Data Field (including HR field);  
Remote Control Field = Immediate Control Field;  
Jump to Next Program Address;

### 23.5.3.19 RCNT (Ratio Count)

**Syntax**

```
RCNT {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [control={OFF | ON}]
    divisor={25-bit unsigned integer}
    [data={25-bit unsigned integer}]
}
```

**Figure 23-133. RCNT Program Field (P31:P0)**

|    |    |          |    |     |                      |    |    |   |      |      |    |            |      |   |   |   |

| 31   | 7 | 6 | 0        |
| Data |   |   | Reserved |
| 25   |   |   | 7        |

**Cycles** Two Cycles (One Cycle if T=0)

**Register modified** None

**Description** RCNT is used with other instructions to convert an input period measurement  $T_{\text{Input}}$  to the form of (Equation 35) where the input period is expressed as a fraction of a reference period  $T_{\text{Reference}}$ .

$$T_{\text{Input}} = T_{\text{Reference}} \cdot \left( \frac{N}{M} \right) \quad (35)$$

RCNT computes the numerator N of (Equation 35). The denominator M of (Equation 35) is a constant that is of interest. For example, choosing allows the input period to be expressed as a percentage (%) of the reference period. Note that if  $T_{\text{Input}} > T_{\text{Reference}}$ , then RCNT will return  $N > M$ ; which would be correct if for example the input pulse period is 110% of the reference pulse period.

RCNT expects that register T is loaded with the value of  $T_{\text{Reference}}$ . The input period  $T_{\text{Input}}$  is determined by counting the number of loop resolution periods between edges on the input pin. This information is conveyed through the Z flag from a PCNT instruction that precedes the RCNT instruction.

The divisor field of the RCNT instruction should be chosen as:  
 $\text{Divisor} = M \cdot l_r$ , where M is the desired denominator from (Equation 35) and  $l_r$  is the loop resolution prescale value.

An example N2HET program that makes use of the RCNT instruction is:

```
L0: MOV32 { remote=dummy, type=IMTOREG, reg=T, data=0x8, hr_data=0};

L1: PCNT { hr_lr=HIGH, brk=OFF, type=FALL2FALL, pin=0};

L2: RCNT { divisor=320, data=0x4};

L3: BR {cond_addr=L5, event = Z}

L4: ADC { src1=ZERO, src2=IMM, dest=IMM, next=L0, data=0, hr_data=0};

L5: ADD { src1=REM, src2=ZERO, dest=IMM, remote=L4, data=0, hr_data=0};

L6: ADD { src1=ZERO, src2=ZERO, dest=NONE, rdest=REM,
        next=L0, remote=L4, data=0, hr_data=0};
```

dummy

In this small program an input signal on pin 0 is measured both in terms of absolute cycles by the PCNT instruction at L1 and as in 1/10ths of the reference period by the RCNT instruction at L2. In this example the reference period is a constant 0x400 cycles; this value is loaded into register T by the MOV32 instruction at L0. (0x400 is data=8, hr\_data=0)

RCNT follows PCNT and is initialized to a working count of T/2 (0x200) whenever the PCNT instruction detects a falling edge on pin 0. Between falling edges on pin0, RCNT accumulates counts 10x faster than PCNT; so that the working data field of RCNT will reach the reference value of 0x400 in 1/10th the time that a PCNT instruction would. Each time the RCNT instruction passes the reference value, it sets the carry out flag and subtracts the reference value from the working count. By accumulating carry-outs from RCNT, the add with carry instruction at L4 effectively counts in increments of 1/10th of the reference period. Note that the divisor value 320 is 10 times 32; this assumes lr=32.

When the next falling edge is detected on pin 0, PCNT sets the Z flag and the RCNT instruction resets again to the initial data field of T/2. RCNT does not modify the Z flag, so that the branch instruction at L3 can execute instructions at L5, L6 instead of L4. The instructions at L5 and L6 capture the final result from L4 and reset the ADC instruction at L4 to zero for the start of the next period measurement.

## Execution

```
If (register T[31:0] != 00000000h)
{
    C = 0;

    If (Z == 0)
    {
        Data Field[31:0] = Data Field[31:0] + Divisor[24:0];

        If (Data Field[31:0] >= Reg T[31:0])
        {
            Data Field[31:0]=Data Field[31:0] - Reg T[31:0];
            C = 1;
        }
    }
    else
    {
        Data Field[31:0] = T[31:0] >> 1; /* T/2 */
    }
}
Jump to Next Program Address;
```

### 23.5.3.20 SCMP (Sequence Compare)

**Syntax**

```

SCMP {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [reqnum={3-bit unsigned integer}]
    [request={NOREQ | GENREQ | QUIET}]
    [control={OFF | ON}]
    [en_pin_action={OFF | ON}]
    cond_addr={label | 9-bit unsigned integer}
    pin ={pin number}
    [action={CLEAR | SET}]
    [restart={OFF | ON}]
    [irq={OFF | ON}]
    [data={25-bit unsigned integer}]
}

```

**Figure 23-136. SCMP Program Field (P31:P0)**

**Figure 23-137. SCMP Control Field (C31:C0)**

**Figure 23-138. SCMP Data Field (D31:D0)**

**Cycles** One

**Register modified** Register T (implicitly)

**Description** This instruction alternately performs angle- and time-based operations to generate pulse sequences, using the angle referenced time base. These pulse sequences last for a relative duration using a free running time base. Generally, register B holds the angle values and register A holds the time values. Bit 0 of the conditional address field (C13) specifies whether the instruction is operating in angle or time operation mode.

When the compared values match in angle mode, a pin can be set or reset according to the pin action bit (C4). The pin does not change states if the enable pin action bit (C22) is reset.

The restart enable bit (C1) provides the option to unconditionally restart a sequence using the X-flag bit of ACMP.

|                  |                                                                                                                                                                                                                                                                                                                                                                            |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>restart</b>   | If restart is set to ON and the X flag = 1, the assembler writes a value of 1 into the immediate index field, writes the value in register A into the immediate data field, and jumps to the next program address. The X flag is set or cleared by the ACMP instruction. If restart is set to OFF, the X flag is ignored; no special action is performed.<br>Default: OFF. |
| <b>irq</b>       | ON generates an interrupt if the compare match occurs in angle mode. No interrupt is generated when the field is OFF.<br>Default: OFF.                                                                                                                                                                                                                                     |
| <b>data</b>      | Specifies the 25-bit compare value.                                                                                                                                                                                                                                                                                                                                        |
| <b>cond_addr</b> | Since the LSB of the conditional address is used to select between time mode and angle mode, and since the conditional address is taken only in time mode, the destination for the conditional address must be odd.                                                                                                                                                        |

## Execution

```

If (Data field value <= Selected register value) Cout = 0; else Cout = 1;

If (Restart Enable == 1 AND X == 1)
{
    C13 = 1;
    Immediate Data Field = Register A;
    Cout = 0;
    Jump to Next Program Address;
}

If (Angle Mode (C13 == 0) AND ((Restart En. == 1 AND X == 0) OR Restart En. == 0))
{
    If (Z == 0 AND (Register B value - Angle Inc. < Data field value) AND Cout == 0) OR
        (Z == 1 AND (Cout_prv == 1 OR Cout == 0))
    {
        If (Enable Pin Action == 1) Selected Pin = Pin Action;
        If (Interrupt Enable == 1) HETFLG[n] = 1; /* n depends on address */
        If ([C28:C27] == 01) Generate request on request line [P25:P23];
        If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];

        Immediate Data Field = Register A;
        C13 = 1; /* switch to Time Mode */
    }
    Jump to Next Program Address;
}
Else If (Time Mode (C13 == 1)) AND ((Restart En. == 1 AND X == 0) OR Restart En. == 0)
{
    /* Result of subtract must not exceed 2^24 - 1 */
    Register T = Register A - Immediate Data Field;
    Jump to Conditional Program Address;
}
Cout_prv = Cout; (always executed)

```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

### 23.5.3.21 SCNT (Step Count)

**Syntax**

```

SCNT {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    step={8 | 16 | 32 | 64}
    [control={OFF | ON}]
    gapstart={25-bit unsigned integer}
    [data={25-bit unsigned integer}]
}

```

|      |   |   |          |
|------|---|---|----------|
| 31   | 7 | 6 | 0        |
| Data |   |   | Reserved |
| 25   |   |   | 7        |

**Cycles** One or two cycles (two cycles when DF is involved in the calculations)

**Register modified** Register A

**Description** This instruction can be used only once in a program and defines a specialized virtual timer used after APCNT and before ACNT to generate an angle-referenced time base synchronized to an external signal (that is, a toothed wheel signal) as defined in APCNT and ACNT. Step width selection bits are saved in two flags, SWF0, and SWF1, to be re-used in ACNT.

SCNT multiplies the frequency of the external signal by a constant *K* defined in the step width field, [P5:P4]. The bit encoding for this field is defined in [Table 23-69](#):

**step** Specifies the step increment to be added to the counter value each program resolution. These two bits provide the values for the SWF0 and SWF1 flags. The valid values are listed in [Table 23-69](#).

**Table 23-69. Step Width Encoding for SCNT**

| P5 | P4 | Step Width (K) |
|----|----|----------------|
| 0  | 0  | 8              |
| 0  | 1  | 16             |

**Table 23-69. Step Width Encoding for SCNT (continued)**

| P5 | P4 | Step Width (K) |
|----|----|----------------|
| 1  | 0  | 32             |
| 1  | 1  | 64             |

|                 |                                                                                                                                                                                                                                                                                                                                  |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>gapstart</b> | Defines the gap start angle, which SCNT writes to register A. The gap start value has no effect on the SCNT instruction, but if the ACNT instruction is being used, register A must contain the correct gap start value. For a typical toothed wheel gear:<br>$GAPSTART = (stepwidth \times (actual\ teeth\ on\ gear - 1)) + 1.$ |
| <b>data</b>     | Specifies the 25-bit integer value serving as a counter.<br>Default: 0.                                                                                                                                                                                                                                                          |

This instruction is incremented by the step value K on each timer resolution up to the previous period value P(n-1) measured by APCNT (stored in register T). The resulting period of SCNT is:  $P(n - 1)/K$

Due to stepping, the final count of SCNT will not usually exactly match the target p(n-1). SCNT compensates for this error by starting each cycle with the remainder of the previous cycle.

When SCNT reaches the target p(n-1), the zero flag is set as an increment condition for ACNT. SCNT also specifies a gap start angle, defining the start of a range in ACNT where period measurements in APCNT are temporarily stopped to mask singularities in the external signal.

SCNT uses register A to store the gap start value. Gap start has no effect for SCNT.

### Execution

```
SWF1 = P5;
SWF0 = P4;
Z = 0;

If (register T != 0000000h)
{
    If (DCF == 1 OR ACF == 1)
    {
        Data Field register = 0000000h;
        Counter value = 0000000h;
    }

    If (DCF == 0 AND ACF == 0)
    {
        Data Field register = Data field register + Step Width;
    }

    If ((Data Field register - register T) >= 0)
    {
        Data field register = Data Field register - register T;
        Z = 1;
    }

    Register A = Gap start value;
}

Jump to Next Program Address;
```

### 23.5.3.22 SHFT (Shift)

**Syntax**

```

SHFT {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [reqnum={3-bit unsigned integer}]
    [request={NOREQ | GENREQ | QUIET}]
    smode={OR0 | OL0 | OR1 | OL1 | ORZ | OLZ | IRM | ILL | IRZ | ILZ}
    [control={OFF | ON}]
    [prv={OFF | ON}]
    [cond_addr={label | 9-bit unsigned integer}]
    cond={UNC | FALL | RISE}
    pin ={pin number}
    [reg={A | B | R | S | T | NONE}]
    [irq={OFF | ON}]
    [data={25-bit unsigned integer}]
}

```

**Figure 23-142. SHFT Program Field (P31:P0)**

**Figure 23-143. SHFT Control Field (C31:C0)**

**Figure 23-144. SHFT Data Field (D31:D0)**

**Cycles** One

**Register modified** Selected register (A, B, R, S or T)

**Description** This instruction shifts the data field of the Instruction. N2HET pins can be used for data in or data out. SHFT includes parameters to select the shift direction (in, out, left, right), shift condition (shift on a defined clock edge on HET[0] or shift always), register for data storage (A, B, R, S or T), and the data pin.

**smode** Shift mode

**Table 23-70. SHIFT MODE Encoding Format**

| smode | P3 | P2 | P1 | P0 | Operation         |                              |
|-------|----|----|----|----|-------------------|------------------------------|
| OR0   | 0  | 0  | 0  | 0  | Shift Out / Right | LSB 1st on HETx / 0 into MSB |
| OL0   | 0  | 0  | 0  | 1  | Shift Out / Left  | MSB 1st on HETx / 0 into LSB |
| OR1   | 0  | 0  | 1  | 0  | Shift Out / Right | LSB 1st on HETx / 1 into MSB |
| OL1   | 0  | 0  | 1  | 1  | Shift Out / Left  | MSB 1st on HETx / 1 into LSB |
| ORZ   | 0  | 1  | 0  | 0  | Shift Out / Right | LSB 1st on HETx / Z into MSB |
| OLZ   | 0  | 1  | 0  | 1  | Shift Out / Left  | MSB 1st on HETx / Z into LSB |
| IRM   | 1  | 0  | 0  | 0  | Shift In / Right  | HETx into MSB                |
| ILL   | 1  | 0  | 0  | 1  | Shift In / Left   | HETx into LSB                |
| IRZ   | 1  | 0  | 1  | 0  | Shift In / Right  | HETx in MSB / LSB into Z     |
| ILZ   | 1  | 0  | 1  | 1  | Shift In / Left   | HETx in LSB / MSB into Z     |

**cond** Specifies the shift condition.

**Table 23-71. SHIFT Condition Encoding**

| C6 | C5 | Shift condition        |
|----|----|------------------------|
| 0  | X  | Always                 |
| 1  | 0  | Rising edge of HET[0]  |
| 1  | 1  | Falling edge of HET[0] |

**irq** ON generates an interrupt if the Z flag is set. A value of OFF does not generate an interrupt.  
Default: OFF.

**data** Specifies the 25-bit value for the data field.

## Execution

```

If (SHIFT condition == 0X)
OR (SHIFT condition == 10 AND HET[0] rising edge)
OR (SHIFT condition == 11 AND HET[0] falling edge)
{
    If ([P3:P2] == 00)
    {
        If ((Immediate Data Field == all 0's AND [P3:P0] == 000X)
            OR (Immediate Data Field == all 1's AND [P3:P0] == 001X))
        {
            Z = 1;
        }
        else
        {
            Z = 0;
        }
    }
}

```

```

    }
    else If ([P3:P0] == 1010)
    {
        Z = LSB of the Immediate Data Field;
    }
    else if ([P3:P0] == 1011)
    {
        Z = MSB of the Immediate Data Field;
    }
}

If( (Immediate Data Field == all 0's) OR
    (Immediate Data Field == all 1's))
{
    if (Interrupt Enable == 1)
    {
        HETFLG[n] = 1;      /* n depends on address */
    }
    Jump to Conditional Address;
}
else
{
    Jump to Next Program Address;
}

Prv. bit = HET[0] Pin level; (Always executed)

Shift Immediate Data Field once according to P[3:0];

Immediate Data Field = Result of the shift;

Selected register = Result of the shift;

Jump to Next Program Address;

```

---

**NOTE:** The immediate data field evaluates all 0s or all 1s and is performed before the shift operation.

---

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

### 23.5.3.23 WCAP (Software Capture Word)

**Syntax**

```

WCAP {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [reqnum={3-bit unsigned integer}]
    [request={NOREQ | GENREQ | QUIET}]
    [hr_lr={HIGH | LOW}]
    [control={OFF | ON}]
    [prv={OFF | ON}]
    [cond_addr={label | 9-bit unsigned integer}]
    pin ={pin number}
    event={NOCOND | FALL | RISE | BOTH}
    reg={A | B | R | S | T | NONE}
    [irq={OFF | ON}]
    [data={25-bit unsigned integer}]
    [hr_data={7-bit unsigned integer}]
}

```

**Figure 23-145. WCAP Program Field (P31:P0)**

**Figure 23-146. WCAP Control Field (C31:C0)**

**Figure 23-147. WCAP Data Field (D31:D0)**

**Cycles** One

**Register modified** None

**Description**

This instruction captures the selected register into the data field if the specified capture condition is true on the selected pin. This instruction can be used with all pins.

If the hr\_lr bit is reset, the WCAP instruction will capture an HR time stamp into the data field on the selected edge condition. If the hr\_lr bit is set, the HR capture is ignored.

**event** Specifies the event that triggers the capture.

**Table 23-72. Event Encoding Format for WCAP**

| C6 | C5 | Capture Condition                  |
|----|----|------------------------------------|
| 0  | 0  | Always                             |
| 0  | 1  | Capture on falling edge            |
| 1  | 0  | Capture on rising edge             |
| 1  | 1  | Capture on rising and falling edge |

**irq** ON generates an interrupt when the capture condition is met. No interrupt is generated for OFF.  
Default: OFF.

**data** Specifies the 25-bit integer value to be written to the data field or selected register.

**hr\_data** HR capture value.  
Default: 0.

**NOTE:** WCAP in HR Mode: The HR Counter starts on a WCAP instruction execution (in the first loop clock) and will synchronize to the next loop clock. When N2HET is turned on and a capture edge occurs in the first loop clock (where the HR counter hasn't been synchronized to the loop clock), then the captured HR counter value is wrong and is of no use. So the captured HR data in the first loop clock should be ignored.

## Execution

```

If (Specified Capture Condition is true on Selected Pin
OR Unconditional capture is selected)
{
    Immediate Data Field = Selected register value;

    If (hr_lr bit == 0) Capture the HR value in Immediate HR Data Field;

    If (Interrupt Enable == 1) HETFLG[n] = 1; /* n depends on address */
    If ([C28:C27] == 01) Generate request on request line [P25:P23];
    If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];

    Jump to Conditional Address;
}

Jump to Next Program Address;

Prv bit = Current Logic (Lx) value of selected pin; (always executed)

```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

### 23.5.3.24 WCAPE (Software Capture Word and Event Count)

#### Syntax

```
WCAPE {
    [brk={OFF | ON}]
    [next={label | 9-bit unsigned integer}]
    [reqnum={3-bit unsigned integer}]
    [request={NOREQ | GENREQ | QUIET}]
    [control={OFF | ON}]
    [prv={OFF | ON}]
    [cond_addr={label | 9-bit unsigned integer}]
    pin = {pin number}
    event={NOCOND | FALL | RISE | BOTH}
    [reg={A | B | R | S | T | NONE}]
    [irq={OFF | ON}]
    [ts_data={25-bit unsigned integer}]
    [ec_data={7-bit unsigned integer}]
}
```

**Figure 23-148. WCAPE Program Field (P31:P0)**

**Figure 23-149. WCAPE Control Field (C31:C0)**

**Figure 23-150. WCAPE Data Field (D31:D0)**

#### Cycles

One

#### Register modified

None

#### Description

This instruction captures the selected register into the data field [D31:D7] and increments an event counter [D6:D0] if the specified capture condition is true on the selected pin. This instruction can be used with all pins, but the time stamp [D31:D7] has loop resolution only.

**event** Specifies the event that triggers the capture.

**Table 23-73. Event Encoding Format for WCAPE**

| C6 | C5 | Capture Condition                  |
|----|----|------------------------------------|
| 0  | 0  | Always                             |
| 0  | 1  | Capture on falling edge            |
| 1  | 0  | Capture on rising edge             |
| 1  | 1  | Capture on rising and falling edge |

**irq** ON generates an interrupt when the capture condition is met. No interrupt is generated for OFF.  
Default: OFF.

**ts\_data** Specifies the 25-bit integer value for [D31:D7]  
Default: 0.

**ec\_data** Specifies the initial 7-bit integer value for [D6:D0].  
Default: 0.

## Execution

```

If (Specified Capture Condition is true on Selected Pin
OR Unconditional capture is selected)
{
    Immediate Data Field[31:7] = Selected register value;
    Immediate Data Field [6:0] = Immediate Data Field [6:0] + 1;

    If (Interrupt Enable == 1) HETFLG[n] = 1;      /* n depends on address */
    If ([C28:C27] == 01) Generate request on request line [P25:P23];
    If ([C28:C27] == 11) Generate quiet request on request line [P25:P23];

    Jump to Conditional Address;
}

Jump to Next Program Address;

Prv bit = Current Logic (Lx) value of selected pin; (always executed)

```

The specific interrupt flag that is triggered depends on the address from which the instruction is executed, see [Section 23.2.7](#).

## High-End Timer Transfer Unit (HTU) Module

This chapter describes the high-end timer transfer unit (HTU) module. The HTU is similar to the DMA (Direct Memory Access) module, but it is specialized to transfer NHET (High End Timer) data to or from the microcontroller RAM.

---

**NOTE:** This chapter describes a superset implementation of the HTU module that includes features and functionality that require DMA. Since not all devices have DMA capability, consult your device-specific datasheet to determine applicability of these features and functions to your device being used.

---

## 24.1 Overview

The HET transfer unit is a dedicated direct memory access controller which transfers data between the NHET RAM and RAM buffers located in the main memory address range. This eliminates time consuming CPU accesses to the NHET RAM to gather measurement data or creating output waveforms and thus freeing up the CPU to perform other tasks.

### 24.1.1 Features

- Independently transfers data between the NHET and the main memory
- 8 double control packets supporting dual buffer configuration
- Transfer requests generated by NHET instructions/events
- One shot, circular and auto switch buffer transfer modes for each double control packet for flexible buffer handling
- Constant and post-increment addressing modes
- 32- or 64-bit transactions
- Programmable memory protection region
- Parity protect control packet RAM
- Extensive diagnostic functionality

## 24.2 Module Operation

The HTU is tightly coupled to the NHET and is not intended to transfer data from other peripheral modules. It initiates transfers with the help of requests generated by the NHET program and configurable control packets. Figure 24-1 shows a system block diagram of the HTU and the main path for the data transfer. The tight coupling and the dedicated bus into the SCR (Switched Central Resource) reduces the amount of data transferred on the peripheral bus, which increases the overall system performance. However if the application decides to use the direct CPU access method to the NHET RAM, it is free to do so.

Figure 24-2 shows a more detailed block diagram of the HTU module.

**Figure 24-1. System Block Diagram**

**Figure 24-2. HTU Block Diagram**

Transfers between NHET RAM and the main memory are triggered by 8 different normal NHET requests. Quiet requests are used for specific cases and are discussed in [Section 24.2.4.1](#). Control packets, which store the source and destination addresses, the transfer count and other information (see [Section 24.5](#)), are associated with the requests. A FIFO decouples the read- and write-path and allows to do data-packing in the case of different read- and write-data sizes. The application can specify a section of memory into or from which the data is transferred. This serves as memory protection in the case that information in the control packet RAM was unintentionally altered and avoids that the HTU can overwrite important application data.

Control packets are implemented as double control packets (DCP) which allow to specify two buffers for the data transfer. This enables the CPU to work with one buffer, while new data is transferred to/from the other buffer.

The control packet defines:

- the start address of the source/destination buffers
- the NHET instruction address location
- how many elements need to be transferred
- the buffer handling

A transfer is triggered when a certain condition (for example, capture, compare condition) is detected by a NHET instruction. The NHET instruction specifies which request line to the HTU will be triggered at the event. The DCPs have a fixed assignment to the request lines and the corresponding assignment can be found in the device datasheet. Once a request is triggered, it starts a frame transfer. A frame can contain one or more elements. Elements are defined as 32-bit or 64-bit words of data.

**Figure 24-3. Example of a HTU Transfer**

## 24.2.1 Data Transfers between Main RAM and NHET RAM

### 24.2.1.1 Addressing Modes

The addressing modes of a control packet need to be distinguished between the main RAM of the CPU and the NHET RAM.

#### Main RAM

For each double control packet (see [Section 24.2.1.3](#)) the addressing mode for the main RAM (RAM0/1) can be configured to constant or post-increment mode in register IHADDRCT.

- **Constant Addressing:** In constant mode, the HTU writes/reads the data to/from the same address in the main RAM.
- **Post-increment Addressing:** In post-increment mode, the HTU writes/reads the data to/from the main RAM by incrementing through the addresses after each transfer. If 32-bit transfers are selected it will automatically increment by 4 Byte, if 64-bit transfers are selected, it will increment by 8 Byte. The examples of Use Cases illustrate the post-increment mode, where the elements of consecutive frames are transferred to/from consecutive locations in the main RAM buffer.

#### NHET RAM

How a DCP addresses the NHET RAM is determined by the initial NHET address, the initial element counter (IETCOUNT) and the NHET addressing mode (ADDMH). The main difference to the main RAM addressing mode is that the HET address is reset to the initial HET address for every first element of a frame. To implement constant addressing, the initial element counter needs to be set to 1. Post-increment addressing is selected by programming the initial element counter to a value other than 1.

### 24.2.1.2 Single Buffer Implementation

In a single buffer implementation, the DCP is set up to transfer data to/from a single buffer in the main RAM. With each transfer request, the programmed number of elements is transferred and the buffer pointer is reset to its starting address after the programmed number of frame transfers have completed.

[Figure 24-4](#) shows the request on one request line of the HTU and the frame running on the assigned control packet visualized by the element counter. In the diagram, the frame has 5 element transfers (element count = 5).

**Figure 24-4. Single Buffer Timing and Memory Representation**

Before the application reads the buffer, it has to disable the control packet to avoid that new data overwrites the buffer while it's being accessed by the application. Regardless of the control packet being disabled at t1 or t2 the last frame will always be completed, since the trigger request has been received already. The application can determine any ongoing transfers by the TIPF flag and the NACP bits.

- **One Shot Buffer Mode:** If TMBA or TMBB is set to one shot buffer mode then the data stream will stop after all elements of buffer A or buffer B have been transferred. This means that the corresponding DCP will be disabled after the last frame was transferred to/from buffer A or B and CFTCTA or CFTCTB decrements to zero.
- **Circular Buffer Mode:** If TMBA or TMBB is set to circular buffer mode, then the data stream will continue back at the start of buffer A or B after all elements of buffer A or B have been transferred. The example of Timing Example for Circular Buffer Mode assumes IETCOUNT=3 (Initial Element Transfer Count), IFTCOUNT=3 (Initial Frame Transfer Count, SIZE=0 (Size of Transfer = 32-bit) and ADDFM=0 (Addressing Mode Main Memory = Post Increment). So there are in total 9 32-bit values in the buffer. It also assumes IFADDRx=10h. "U" means uninitialized.

**Figure 24-5. Timing Example for Circular Buffer Mode**

### 24.2.1.3 Dual Buffer Implementation

The transfer unit provides **double control packets (DCPs)** supporting the use of two buffers per data stream (per HTU request source). If one buffer should be read by the CPU or DMA, the data stream is directed to the other buffer and the first buffer is frozen. Switching to the other buffer can be triggered with a write access to the CPENA register or with the DCP configured to automatically switch to the other buffer when the programmed number of frames has been transmitted. Freezing the buffer avoids this buffer to be overwritten with new HET data while the CPU or DMA reads this buffer.

Figure 24-6 shows a timing example of two HET instructions 1 and 2, which are the request sources for the HTU (and are controlled by DCP 1 and DCP 2). Each generated frame has 5 element transfers. Request source 1 has two RAM buffers, controlled by two control packets 1A and 1B. Request source 2 has two RAM buffers, controlled by two control packets 2A and 2B.

Figure 24-6. Dual Buffer Timing

Figure 24-6 shows a switch at time  $t_1$ , where buffer 1A is frozen and data stream 1 is directed to buffer 1B, but only after the frame has been completed. It also shows the time ( $t_2$  or  $t_3$ ) where 2A is frozen and data stream 2 is directed to buffer 2B. If the switch happens between the request and the start of the frame (for example, time  $t_3$ ), then the frame is processed by the new control packet (although the old control packet was active at the time of the request). The delays between the HTU requests and the start of the element transfers result from the fact that the HTU can process only one transfer at a time.

#### Auto Switch Buffer Mode

If TMBA is set to auto switch mode, then the data stream will continue at the start of buffer B after all elements of buffer A have been transferred. This means that in the CPENA register, CP A is disabled and CP B is enabled automatically and buffer B uses its initial main memory address and initial frame counter to start. The same principle is valid for TMBB and buffer B.

The examples of Figure 24-7 assumes IETCOUNT=3 (Initial Element Transfer Count), IFTCOUNT=3 (Initial Frame Transfer Count, SIZE=0 (Size of Transfer = 32-bit) and ADDFM=0 (Addressing Mode Main Memory = Post Increment). So there are in total 9 32-bit values in buffer A and B. It also assumes IFADDRB=10h and IFADDRA=40h. "U" means uninitialized.

**Figure 24-7. Timing Example for Auto Switch Buffer Mode**

#### 24.2.1.4 General Control Packet Behavior

The action defined by the selected mode will be performed at the end of the last frame, which has the frame counter value of 1. The one shot and auto switch mode will automatically update the CPENA register at this time. Note, that for all three modes listed above, it is possible to switch to the other buffer by writing to CPENA before the end of the current buffer is reached.

If a write access to CPENA happens while the last frame of DCP x (with frame counter = 1) is transferred then the priority is defined by Table 24-1.

**Table 24-1. CPENA / TMBx Priority Rules**

| Write access to CPENA bits (2*x+1) and (2*x) during the frame with frame counter = 1 <sup>(1)</sup> | Priority Rule                                                                   |
|-----------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Disable:<br>01 --> 00 or<br>10 --> 00                                                               | Disabling the DCP by the write to CPENA has priority, TMBx is ignored.          |
| Stay:<br>01 --> 01 or<br>10 --> 10                                                                  | The write access to CPENA is ignored, TMBx has priority and defines the action. |
| Switch:<br>01 --> 10 or<br>10 --> 01                                                                | Switching the DCP by the write to CPENA has priority, TMBx is ignored.          |

<sup>(1)</sup> See read table of CPENA register

There could be a case where the CPU wants to do main memory operations, but does not want the HTU modifying the main memory. It could happen that a request was already active, but the frame transfer hasn't started yet when the application disabled the control packets. The timing diagram in [Figure 24-8](#) shows this scenario.

**Figure 24-8. Timing for Disabling Control Packets**

Since the request for the transfer was already received before the DCPx is disabled, the HTU will still start the frame transfer. The application would poll the BUSYx bit during the time the DCPx was disabled and before the frame was started and would read a non-busy information. It then would start the main memory operations thinking all transfers have completed, however after some time the HTU will start the outstanding frame transfer and corrupt the main memory.

To avoid this, the application can set the VBUSHOLD bit to disable all transactions between the HTU and the main memory. It has to poll the BUSBUSY bit to ensure that no outstanding transactions on the bus are pending. The HTU will still receive all transfer requests from the NHET, but it will not be able to transfer any data to or from the main memory, while the VBUSHOLD bit is set.

### 24.2.2 Arbitration of HTU Elements and Frames

- Frames do not interrupt each other. If a request occurs on DCP x while another frame runs on DCP y (and  $x \neq y$ ), then the current frame completes before the new frame starts.
- If two or more request lines are active, the request line with the lower number (specified in the request number field of the corresponding NHET instruction) is serviced first.

### 24.2.3 Conditions for Frame Transfer Interruption

If a frame is currently transferred on DCP x and one of the events listed below happens, then the event will (1.) clear the element counter of DCP x, (2.) stop new element transfers on DCP x (3.) clear the active busy bit of DCP x and (4.) disable DCP x in the CPENA register. The DCPs other than DCP x will not be affected.

- Request Lost Error of DCP x (with CORL bit set to zero).
- Parity Error of DCP x (with parity check enabled and COPE bit set to zero). See also [Section 24.2.6](#).
- Bus Error of DCP x.
- Memory Protection Error of DCP x (with memory protection enabled). See also [Section 24.2.5](#).
- Writing a one to a BUSY bit (belonging to DCP x) if that bit is one. There is no effect if the BUSY bit is zero.
- Writing a one to the HTURES bit.

When a memory protection error occurs, the access to the protected address is blocked. The frame is stopped before the element, which caused the violation transfer, starts. All other errors will let the current element transfer finish.

In case of the Request Lost and Bus Error, one more element transfer goes on the bus, before the frame is actually stopped. Accordingly, the busy bit is cleared after the element, which follows the element that caused the error.

In case of the Bus Error, the counter for the element, which follows the element that caused the error, is captured to the ERRETC register field.

**NOTE:** If the HTUEN bit is cleared during a frame is transferred, then the frame will be completed before the HTU is disabled.

#### 24.2.4 HTU Overload and Request Lost Detection

If the number of different HTU request sources is "high", the period between the requests is "short" and/or the initial element counter values are "big", then the HTU could get into a overload situation. In [Figure 24-9](#), all requests marked with "L" are lost, since their frame is not completed at the time the next request occurs. Each number in the rows "TU request (x)" represents a time, where the associated NHET instruction generates a request on DCP x. The arrows in [Figure 24-9](#) point to the associated frame, which could be delayed compared to the request. The delays are caused by different frames, which are currently processed. The figure assumes that the CORL bit in the RLBECTRL register is set, which causes the DCP to stay enabled and let the data stream continue after a request lost error occurred on the DCP (see 3-L for TU request (2)).

**Figure 24-9. Timing Example Including Lost Requests**

Lost requests are signaled with the RLOSTFL register, and if enabled, can generate request lost interrupts.

If the CORL bit is set, a frame will be completed and the corresponding DCP stays enabled even if a request lost was generated during this frame.

In dual buffer mode, the request lost detection works continuously, independent of the CP switches.

##### 24.2.4.1 Requests and Quiet Requests

In addition to generating too many transfer requests and thus overloading the HTU and not being able to transfer data at all, it can happen that inconsistent data is transferred. The following examples illustrate such scenarios.

In the examples below, the HTU reads a frame of three elements from the datafield of three different instructions. In [Figure 24-10](#), the L3-Instruction generates the HTU request at time t2, t7, etc. and the according frame (at t3). The frame is delayed because of the HTU load. However, as shown in [Figure 24-10](#), the delay still allows the frame to complete before the datafield of instruction L1 is updated again. However, when the delay is longer (as shown in [Figure 24-11](#)), then the frame could fall into the NHET loop (LRP), in which the NHET updates the data fields of the L1, L2 and L3 instructions. In this case, the HTU could read inconsistent data as shown in the diagram. A wrong (new) value is read from L1 (at time t3), but correct ("old") values are read from L2 and L3 (at times t4 and t5).

**Figure 24-10. Timing which Generates No Request Lost Error**

**Figure 24-11. Timing which Generates a Request Lost Error**

To ensure consistent data, the NHET instructions are able to generate a **quiet request**, which does not originate a transfer but is only used by the HTU for consistency check. If a frame has not completed since the last request (or has not even started) at the time the quiet request occurs, then the HTU signals a request lost error. All instructions, which allow to generate a request can be configured to generate a quiet request instead. So in the examples of [Figure 24-10](#) and [Figure 24-11](#), instruction L1 should be configured to generate a quiet request and instruction L3 to generate a normal request. In the case of [Figure 24-11](#), the corresponding bit in the RLOSTFL register will be set.

It is the responsibility of the NHET software to enable a quiet request for the first instruction of an instruction block, which is addressed by DCP x, and to enable a normal request only for the last instruction of this block. Since enabling the quiet request should enable a proper request lost detection for DCP x, both NHET instructions need to specify the same DCP x (reqnum=x).

The control fields of the HET instructions provide a 2-bit field to configure one of the following possibilities (as shown in [Table 24-2](#)). A 3-bit field in the program field will select which of the 8 Double Control Packets will be triggered by the request.

**Table 24-2. Triggered Control Packets**

| Request Type Bit 1 | Request Type Bit 0 |                         | Request Number                                                          |
|--------------------|--------------------|-------------------------|-------------------------------------------------------------------------|
| Don't care         | 0                  | No request              | Specify number 0, 1,... or 7, which selects the HTU or DMA request line |
| 0                  | 1                  | Generate normal request |                                                                         |
| 1                  | 1                  | Generate quiet request  |                                                                         |

In the case of very light HTU load, but higher signal requirements (for example, high frequency), the quiet request could also be used to define periods in which the data read by a control packet is safe. The following HET code will capture counter time stamps to the L1-WCAP data field after rising edges (at pin CC6) and to the L2-WCAP data field after falling edges (at pin CC6):

```
L0 CNT {reg=A, max=0x1FFFFFFF}
L1 WCAP {reqnum=3, request=GENREQ, event=RISE, reg=A, pin=CC6}
L2 WCAP {reqnum=3, request=QUIET, event=FALL, reg=A, pin=CC6}
; HET HRSHARE feature configured to assign both WCAPs to pin CC6
```

**Figure 24-12. Timing Example for Two WCAP Instructions**

The HTU frame will have two elements: The first gives the time stamp of the rising edge  $r(n)$  and the second gives the time stamp of the previous falling edge  $f(n-1)$ . Using the code above, requests (R) and the quiet requests (QR) will occur at the times shown in Figure 24-12, and a request lost will only be signaled when the frame makes an access during the times marked with RL. So reading [22, 21] as frame elements is correct. If the signal frequency would increase, then a wrong pair [22, 24] could be read, but this will be signaled by a request lost error since at least e2 falls into the RL period.

### 24.2.5 Memory Protection

This feature allows restricting accesses to certain areas in memory in order to protect critical application data from unintentionally being manipulated by the HTU.

If the HTU memory protection feature is disabled, the full 4 GB address range can be accessed by the HTU without exception. There are two memory regions which start and end addresses can be configured. With the memory protection feature enabled, read and write accesses by the HTU inside the defined regions are allowed. For accesses outside the regions, one of two modes is configurable:

- Any access performed by the HTU is forbidden and will be signaled to the ESM module. Write accesses will be blocked.
- Read access is allowed but write access will be blocked and signaled to the ESM module.

To use one region only, REG01ENA must be zero. Bits ACCR01, INTENA01, and register settings of MP1S, and MP1E will be ignored.

To use both regions, the rules below must be followed:

1. Memory mapped region 0 covers a lower memory area as Memory mapped region 1.
2. REG01ENA is a one and REG0ENA is a zero.
3. ACCR01 is set for the desired access type, ACCR0 is ignored.
4. INTENA01 is set for the desired action, INTENA0 is ignored.

If an element transfer of DCP x generates a memory protection error, then:

1. The element counter of DCP x is cleared.
2. All new element transfers on DCP x are stopped.
3. The active busy bit of DCP x is cleared.
4. DCP x is disabled in the CPENA register. The DCPs other than DCP x will not be affected.
5. The FT flag will be set.
6. An error is signaled to the ESM module.

#### 24.2.6 Control Packet RAM Parity Checking

The HTU module can detect parity errors in the DCP (Double Control Packet) RAM. DCP RAM parity checking is implemented using one parity bit per byte. Even or odd parity checking can be selected in the DEVCR1 register of the system module and can be enabled/disabled by a 4-bit key in the PCR register.

During a read access to the DCP RAM, the parity is calculated based on the data read from the RAM and compared with the good parity value stored in the parity bits. The parity check is performed when the HTU or any other master (for example, CPU) makes a read access to the DCP RAM. A read access within the RAM section of an initial or current DCP checks all 16 bytes of the DCP at a time (see also DCP memory map). For example, if a byte read access happens for DCP RAM address 0, but there is a parity error at byte address Ch then the parity error will occur and the captured parity address will be Ch and not 0. The address of the byte in which the error occurred can be read from the PAR register. If successive DCP RAM read accesses generate multiple parity errors, only the address of the first detected error will be captured and the PAR register will not be updated by subsequent errors until it is read by the application. When multiple errors in a 16 byte word are detected, only the address of the lowest byte will be captured.

The application can decide whether to stop any transfers when a parity error is detected or to continue transferring data. If the COPE (Continue On Parity Error) bit is zero and parity checking is enabled, then the HTU will not start the frame and the corresponding DCP will be automatically disabled in the CPENA register. If a master other than the HTU (for example, CPU) reads the RAM section of DCP x and a parity error is detected during this read access, while the parity check is enabled and the COPE bit is zero, then the DCP x will be automatically disabled in the CPENA register. If a frame for this DCP x is ongoing during this read access, then in addition the element counter of DCP x is cleared, all new element transfers on DCP x are stopped and the active busy bit of DCP x is cleared. With COPE set to one and the parity check enabled, the parity checking will still be performed, but the data transfer of an active DCP continues after a parity error was detected for this DCP. So neither the DCP with the parity error will be disabled nor the frame will be stopped.

After a DCP is enabled (with CPENA using BIM=0), then at the start of the first frame, the HTU performs the parity check only on the initial DCP, since it does not need the current DCP information. For further frames, the HTU performs the parity check for both initial and current DCP, since it needs both information.

On a parity error detection, an error will also be signaled to the ESM module.

### 24.2.6.1 Parity Bit Mapping and Testing

To test the parity checking mechanism, the parity RAM can be made accessible in order to allow manual fault insertion. Once the TEST bit is set, the parity bits are mapped to address FF4E 0200h.

When in test mode (the parity RAM is accessible), no parity checking will be done when reading from parity RAM, but parity checking will still be performed for read accesses to the DCP RAM.

Table 24-3 and Table 24-4 show how the corresponding parity bits of the DCP RAM bytes are mapped into the memory.

**Table 24-3. DCP RAM**

| Bit        | 31      | 24 | 23      | 16 | 15      | 8 | 7       | 0 |
|------------|---------|----|---------|----|---------|---|---------|---|
| FF4E 0000h | Byte 0  |    | Byte 1  |    | Byte 2  |   | Byte 3  |   |
| FF4E 0004h | Byte 4  |    | Byte 5  |    | Byte 6  |   | Byte 7  |   |
| FF4E 0008h | Byte 8  |    | Byte 9  |    | Byte 10 |   | Byte 11 |   |
| FF4E 000Ch | Byte 12 |    | Byte 13 |    | Byte 14 |   | Byte 15 |   |

**Table 24-4. DCP Parity RAM**

| Bit        | 24  | 16  | 8   | 0   |
|------------|-----|-----|-----|-----|
| FF4E 0200h | P0  | P1  | P2  | P3  |
| FF4E 0204h | P4  | P5  | P6  | P7  |
| FF4E 0208h | P8  | P9  | P10 | P11 |
| FF4E 020Ch | P12 | P13 | P14 | P15 |

Each byte in DCP RAM has its own parity bit in the DCP Parity RAM. P0 is the parity bit for byte 0, P1 is the parity bit for byte 1 and so on.

### 24.2.6.2 Initializing Parity Bits

After device power up, the DCP RAM content including the parity bit cannot be guaranteed. In order to avoid parity failures, when reading DCP RAM, the RAM has to be initialized first. This can simply be done by writing known values into the RAM by software and the corresponding parity bit will be automatically calculated.

Another possibility to initialize the DCP memory and its parity bits is to use the system module, which is an on-chip module external to the HTU. This module can start the automatic initialization of all RAMs on the microcontroller including the HTU DCP RAM. This function initializes the complete DCP RAM to '0' when activated by the system module. Depending on the even/odd parity selection, all parity bits will be calculated accordingly. The HTUEN bit must be cleared and the parity functionality must be enabled (by PARITY\_ENA) during the automatic DCP RAM initialization. If HTUEN is one when the initialization is triggered by the system module, then the initialization will not be performed and the HTU operation is not affected. If a one is written to HTUEN during the initialization, then the HTUEN bit will be set but the HTU will not be enabled before the initialization completes.

## 24.3 Use Cases

### 24.3.1 Example: Single Element Transfer with One Trigger Request

This example considers the case that the HTU fills a RAM buffer in the main (CPU) data RAM. The HTU reads from the instruction which generates the HTU requests.

This example uses a PCNT instruction. Every time the PCNT has captured a new pulse or period value, it will automatically generate a transfer request to the HTU, which then transfers the value from the NHET RAM to the buffer RAM. So over time consecutive locations in the RAM buffer can be filled with consecutive measurement values captured into the NHET RAM data field of the same PCNT instruction without loading or interrupting the CPU.

### 24.3.2 Example: Multiple Element Transfer with One Trigger Request

The following example shows how the HTU could be used to fill a RAM buffer with a data stream including different types of measurement values belonging to the same NHET input signal (on one pin): Time stamp values (WCAP), edge counter values (ECNT) and last period values (PCNT).

Figure 24-13 shows the timing and Table 24-5 shows the byte addresses of the program- (PF), control- (CF), data- (DF) and reserved field (res) of the WCAP-ECNT-PCNT instruction block. The timing and code example assumes that all three instructions are assigned to the same NHET pin.

**Figure 24-13. Timing of the WCAP, ECNT, PCNT Example**

**Table 24-5. Field Addresses of the WCAP, ECNT, PCNT Example**

|      | PF  | CF  | DF  | Res |
|------|-----|-----|-----|-----|
| WCAP | 30h | 34h | 38h | 3Ch |
| ECNT | 40h | 44h | 48h | 4Ch |
| PCNT | 50h | 54h | 58h | 5Ch |

In the HET code the HTU request is enabled only for the last instruction (PCNT) of the WCAP-ECNT-PCNT block. When the PCNT condition is true, it will cause the generated HTU frame to perform three HTU element reads from the data fields of WCAP, ECNT and PCNT.

#### 32-Bit-Transfer of data fields:

The following diagram shows how the internal element counter, frame counter and the address registers change over time for the example described above. Every time the PCNT instruction captures a new value it generates a request to the HTU, which starts a frame. At the end of each frame the frame counter decrements.

**Table 24-6. 32-Bit-Transfer of Data Fields <sup>(1)</sup>**

|                                    |     |     |     |     |     |     |     |     |     |
|------------------------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Frame Counter                      | 3   |     |     | 2   |     |     | 1   |     |     |
| Element Counter                    | 3   | 2   | 1   | 3   | 2   | 1   | 3   | 2   | 1   |
| Source Address (HET)               | 38h | 48h | 58h | 38h | 48h | 58h | 38h | 48h | 58h |
| Destination Address (main CPU RAM) | 70h | 74h | 78h | 7Ch | 80h | 84h | 88h | 8Ch | 90h |

<sup>(1)</sup> The diagram shows the byte addresses

The destination buffer is filled with the WCAP, ECNT and PCNT data field values as shown below.

**Table 24-7. Destination Buffer Values**

| Address | Frame Count | Instruction | Value |
|---------|-------------|-------------|-------|
| 70h     | 3           | WCAP        | 3     |
| 74h     | 3           | ECNT        | 1     |
| 78h     | 3           | PCNT        | 2     |
| 7Ch     | 2           | WCAP        | 6     |
| 80h     | 2           | ECNT        | 2     |
| 84h     | 2           | PCNT        | 3     |
| 88h     | 1           | WCAP        | 10    |
| 8Ch     | 1           | ECNT        | 3     |
| 90h     | 1           | PCNT        | 4     |

The corresponding setup of the HTU control packet for this example is as follows:

```

IHADDR   = 0x38           // points to WCAP data field
IFADDRA  = 0x70           // points to buffer
ITCOUNT [frame count = 3] [element count = 3]
IHADDRCT = [DIR: Read HET and write to full address]
           [SIZE: 32 bit]
           [ADDMH: Increment HET address by 16 bytes]
           [ADDMP: Post increment full address mode]
           [Any transfer mode]

```

### 24.3.3 Example: 64-Bit-Transfer of Control Field and Data Fields

The following diagram shows how the internal element counter, frame counter and the address registers change over time assuming the same example as in [Section 24.3.2](#), but now with a transfer size set to 64-bit. The HET address now points to the control field of the instruction, so CF and DF are transferred as 64 bit data.

**Table 24-8. 64-Bit-Transfer of Control Field and Data Fields <sup>(1)</sup>**

|                            |     |     |     |     |     |     |     |     |     |
|----------------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Frame Counter              | 3   |     |     | 2   |     |     | 1   |     |     |
| Element Counter            | 3   | 2   | 1   | 3   | 2   | 1   | 3   | 2   | 1   |
| HET (Source) Address       | 34h | 44h | 54h | 34h | 44h | 54h | 34h | 44h | 54h |
| Full (Destination) Address | 70h | 78h | 80h | 88h | 90h | 98h | A0h | A8h | B0h |

<sup>(1)</sup> The diagram shows the byte addresses.

The destination buffer is filled with the WCAP, ECNT and PCNT control and data field values as shown on the right.

**Table 24-9. Destination Buffer Values**

| Address | Frame Count | Instruction | Value               |
|---------|-------------|-------------|---------------------|
| 70h     | 3           | WCAP        | Control Field Value |
| 74h     | 3           | WCAP        | 3                   |
| 78h     | 3           | ECNT        | Control Field Value |
| 7Ch     | 3           | ECNT        | 1                   |
| 80h     | 3           | PCNT        | Control Field Value |
| 84h     | 3           | PCNT        | 2                   |
| 88h     | 2           | WCAP        | Control Field Value |
| 8Ch     | 2           | WCAP        | 6                   |
| 90h     | 2           | ECNT        | Control Field Value |
| 94h     | 2           | ECNT        | 2                   |
| 98h     | 2           | PCNT        | Control Field Value |
| 9Ch     | 2           | PCNT        | 3                   |
| A0h     | 1           | WCAP        | Control Field Value |
| A4h     | 1           | WCAP        | 10                  |
| A8h     | 1           | ECNT        | Control Field Value |
| ACh     | 1           | ECNT        | 3                   |
| B0h     | 1           | PCNT        | Control Field Value |
| B4h     | 1           | PCNT        | 4                   |

The necessary setup of the HTU control packet (see [Section 24.5](#)) for this example is as follows:

```

IHADDR  = 0x34 (points to WCAP control field)
IFADDR  = 0x70 (points to buffer)
ITCOUNT [frame count = 3] [element count = 3]
IHADDRCT = [DIR: Read HET and write to full address]
           [SIZE: 64 bit]
           [ADDMH: Increment HET address by 16 bytes]
           [ADDMF: post increment full address mode]
           [Any transfer mode]

```

For different applications, which have the transfer direction set for reading the buffer and writing to HET fields, the 64-bit transfer could be used to change the conditional addresses together with a new data field.

## 24.4 Control Registers

[Table 24-10](#) provides a summary of the registers. The registers support 8-bit, 16-bit, and 32-bit writes. The offset is relative to the associated peripheral select. See the following sections for detailed descriptions of the registers. The base address for the control registers is FFF7 A400h. The address locations not listed, are reserved.

| 31-16 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                   |
| 15-0  | CPENA    |       | CP Enable Bits<br>Bits (2*x) and (2*x+1) of CPENA control the double control packet (DCP) x (whereby x must be within 0,1,...,7).<br>See <a href="#">Table 24-13</a> for write rules.<br>See <a href="#">Table 24-14</a> for read rules. |

**Table 24-13. CPENA Write Results**

| Bit (2*x+1) | Bit (2*x) | Control packets (CP) B and A of DCP x are affected as follows: |
|-------------|-----------|----------------------------------------------------------------|
| 0           | 0         | CP B and A are not changed                                     |
| 0           | 1         | CP B is disabled and CP A are enabled simultaneously           |
| 1           | 0         | CP B is enabled and CP A are disabled simultaneously           |
| 1           | 1         | CP B and CP A are both disabled simultaneously                 |

**Table 24-14. CPENA Read Results**

| Bit (2*x+1) | Bit (2*x) | State of DCP:                        |
|-------------|-----------|--------------------------------------|
| 0           | 0         | The DCP is disabled                  |
| 0           | 1         | CP B is disabled and CP A is enabled |
| 1           | 0         | CP B is enabled and CP A is disabled |
| 1           | 1         | Cannot be read                       |

- The conditions listed in [Section 24.2.3](#) can automatically disable DCP x. In this case bits (2\*x) and (2\*x+1) are both automatically set to zero.
- When bits (2\*x) and (2\*x+1) change from 00 to 01 or from 00 to 10 caused by a write access to CPENA, then old pending requests on the corresponding request line are cleared. This means only new requests which occur **after** this write access cause the first HTU transfer for this DCP. This is **not** the case when **switching** CPs (from 10 to 01 or from 01 to 10).
- CP A and/or CP B of a DCP can be configured to one-shot, circular or auto-switch transfer mode via the TMBA or TMBB bits in the IHADDRCT control packet configuration. If a write access to CPENA occurs during the last frame of a buffer (with frame counter = 1) then the action defined by the write access to CPENA and the action defined by TMBx can contradict. The priority rules for this case are given in [Table 24-1](#).

### 24.4.3 Control Packet (CP) Busy Register 0 (HTU BUSY0)

This register displays the status of individual control packets.

**Figure 24-16. Control Packet (CP) Busy Register 0 (HTU BUSY0) [offset = 08h]**

| 7-1   | Reserved | 0     | Read returns 0. Writes have no effect. |
| 0     | BUSY1B   |       | Busy Flag for CP B of DCP 1            |

The bit is **set** when the frame on the according control packet **starts** (as shown in the diagram below, there could be a delay between the request and the start of the frame).

The bit is automatically **cleared** at any of the following conditions:

- At the end of a frame.
- Writing a 1 to a BUSY bit (of DCP x) if that bit is 1. This will:
  - clear the element counter of DCP x,
  - stop all new element transfers on DCP x
  - clear the busy bit and (4.) disable DCP x in the CPENA register.
  - there is no effect if the BUSY bit is zero.
- At the conditions listed in [Section 24.2.3, Conditions for Frame Transfer Interruption](#).

A write access to the CPENA register can stop a control packet (CP) in single buffer mode or it can switch to the other CP of a DCP in dual buffer mode. If stopping or switching occurs while a frame runs on the currently active control packet, the CPU can poll the busy bit to determine when it is safe to read the buffer.

## 24.4.4 Control Packet (CP) Busy Register 1 (HTU BUSY1)

This register displays the status of individual control packets.

**Figure 24-17. Control Packet (CP) Busy Register 1 (HTU BUSY1) [offset = 0Ch]**

|       |          | 1     | No error occurred                                                                                                                                                                                                                                                                                                                                               |
|       |          |       | This bit is set when one of the conditions listed at ERRETC is fulfilled and ERRETC and ERRCPN are captured. Once ERRF is set, it is cleared when reading the upper 16-bit word of the ACPE register or the complete 32-bit register. It is also cleared when writing a one to ERRF. ERRF can be used to indicate if ERRETC and ERRCPN contain new unread data. |
| 30-29 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                          |
