

# **TMS570LS12x/11x 16/32-Bit RISC Flash Microcontroller**

## **Technical Reference Manual**

Literature Number: SPNU515A  
September 2013

|                                                           |            |
|-----------------------------------------------------------|------------|
| <b>Preface</b>                                            | <b>95</b>  |
| <b>1 Introduction</b>                                     | <b>96</b>  |
| 1.1 Designed for Safety Applications                      | 97         |
| 1.2 Family Description                                    | 97         |
| 1.3 Endianism Considerations                              | 100        |
| 1.3.1 TMS570: Big Endian (BE32)                           | 100        |
| <b>2 Architecture</b>                                     | <b>101</b> |
| 2.1 Introduction                                          | 102        |
| 2.1.1 Architecture Block Diagram                          | 102        |
| 2.1.2 Definitions of Terms                                | 103        |
| 2.1.3 Bus Master / Slave Access Privileges                | 105        |
| 2.2 Memory Organization                                   | 106        |
| 2.2.1 Memory Map Overview                                 | 106        |
| 2.2.2 Memory Map Table                                    | 107        |
| 2.2.3 Flash on Microcontrollers                           | 111        |
| 2.2.4 On-Chip SRAM                                        | 113        |
| 2.3 Exceptions                                            | 118        |
| 2.3.1 Resets                                              | 118        |
| 2.3.2 Aborts                                              | 118        |
| 2.3.3 System Software Interrupts                          | 120        |
| 2.4 Clocks                                                | 121        |
| 2.4.1 Clock Sources                                       | 121        |
| 2.4.2 Clock Domains                                       | 122        |
| 2.4.3 Low Power Modes                                     | 124        |
| 2.4.4 Clock Test Mode                                     | 126        |
| 2.4.5 Safety Considerations for Clocks                    | 127        |
| 2.5 System and Peripheral Control Registers               | 130        |
| 2.5.1 Primary System Control Registers (SYS)              | 130        |
| 2.5.2 Secondary System Control Registers (SYS2)           | 183        |
| 2.5.3 Peripheral Central Resource (PCR) Control Registers | 190        |
| <b>3 Power Management Module (PMM)</b>                    | <b>205</b> |
| 3.1 Overview                                              | 206        |
| 3.1.1 Main Features of the Power Management Module (PMM)  | 206        |
| 3.1.2 Block Diagram                                       | 206        |
| 3.2 Power Domains                                         | 208        |
| 3.3 PMM Operation                                         | 209        |
| 3.3.1 Power Switch                                        | 209        |
| 3.3.2 Power Domain State                                  | 209        |
| 3.3.3 Default Power Domain State                          | 209        |
| 3.3.4 Disabling a Power Domain Permanently                | 209        |
| 3.3.5 Changing Power Domain State                         | 209        |
| 3.3.6 Reset Management                                    | 210        |
| 3.3.7 Diagnostic Power State Controller (PSCON)           | 210        |
| 3.3.8 PSCON Compare Block                                 | 210        |
| 3.4 PMM Registers                                         | 211        |

|          |                                                                           |            |
|----------|---------------------------------------------------------------------------|------------|
| 3.4.1    | LOGICPDPWRCTRL0 Register (offset = 0h) [reset = 0h]                       | 213        |
| 3.4.2    | MEMPDPWRCTRL0 Register (offset = 10h) [reset = 0h]                        | 214        |
| 3.4.3    | PDCLKDIS Register (offset = 20h) [reset = 0h]                             | 215        |
| 3.4.4    | PDCLKDISSET Register (offset = 24h) [reset = 0h]                          | 216        |
| 3.4.5    | PDCLKDISCLR Register (offset = 28h) [reset = 0h]                          | 217        |
| 3.4.6    | LOGICPDPWRSTAT0 Register (offset = 40h) [reset = 0h]                      | 218        |
| 3.4.7    | LOGICPDPWRSTAT1 Register (offset = 44h) [reset = 0h]                      | 219        |
| 3.4.8    | LOGICPDPWRSTAT2 Register (offset = 48h) [reset = 0h]                      | 220        |
| 3.4.9    | LOGICPDPWRSTAT3 Register (offset = 4Ch) [reset = 0h]                      | 221        |
| 3.4.10   | MEMPDPWRSTAT0 Register (offset = 80h) [reset = 0h]                        | 222        |
| 3.4.11   | MEMPDPWRSTAT1 Register (offset = 84h) [reset = 0h]                        | 224        |
| 3.4.12   | GLOBALCTRL1 Register (offset = A0h) [reset = 0h]                          | 226        |
| 3.4.13   | GLOBALSTAT Register (offset = A8h) [reset = 0h]                           | 227        |
| 3.4.14   | PRCKEYREG Register (offset = ACh) [reset = 0h]                            | 228        |
| 3.4.15   | LPDDCSTAT1 Register (offset = B0h) [reset = 0h]                           | 229        |
| 3.4.16   | LPDDCSTAT2 Register (offset = B4h) [reset = 0h]                           | 230        |
| 3.4.17   | MPDDCSTAT1 Register (offset = B8h) [reset = 0h]                           | 231        |
| 3.4.18   | MPDDCSTAT2 Register (offset = BCh) [reset = 0h]                           | 232        |
| 3.4.19   | ISODIAGSTAT Register (offset = C0h) [reset = 0h]                          | 233        |
| <b>4</b> | <b>I/O Multiplexing and Control Module (IOMM)</b>                         | <b>234</b> |
| 4.1      | Overview                                                                  | 235        |
| 4.2      | Main Features of I/O Multiplexing Module (IOMM)                           | 235        |
| 4.3      | Control of Multiplexed Outputs                                            | 235        |
| 4.4      | Control of Multiplexed Inputs                                             | 236        |
| 4.5      | Control of Special Multiplexed Options                                    | 237        |
| 4.5.1    | Control of SDRAM clock (EMIF_CLK)                                         | 237        |
| 4.5.2    | Control for other EMIF Outputs                                            | 237        |
| 4.5.3    | Control for Fast Mode for Synchronous and Asynchronous EMIF               | 238        |
| 4.5.4    | Control of Ethernet Controller Mode                                       | 238        |
| 4.5.5    | Control of ADC Trigger Events                                             | 238        |
| 4.5.6    | Control for ADC Event Trigger Signal Generation from eTPWMx Modules       | 239        |
| 4.5.7    | Control for Generating Interrupt Upon External Fault Indication to N2HETx | 241        |
| 4.5.8    | Control for Enabling Clocks to eTPWMx Modules                             | 241        |
| 4.5.9    | Control for Enabling Clocks to eCAPx Modules                              | 242        |
| 4.5.10   | Control for Enabling Clocks to eQEPx Modules                              | 242        |
| 4.5.11   | Control for Synchronizing Time Bases for All eTPWMx Modules               | 242        |
| 4.5.12   | Control for Synchronizing all eTPWMx Modules to N2HET1 Module Time-Base   | 243        |
| 4.5.13   | Control for Input Connections to eTPWMx Modules                           | 244        |
| 4.5.14   | Control for Input Connections to eCAPx Modules                            | 245        |
| 4.5.15   | Control for Input Connections to eQEPx Modules                            | 245        |
| 4.6      | Safety Features                                                           | 246        |
| 4.6.1    | Locking Mechanism for Memory-Mapped Registers                             | 246        |
| 4.6.2    | Master ID Check                                                           | 246        |
| 4.6.3    | Error Conditions                                                          | 246        |
| 4.7      | IOMM Registers                                                            | 246        |
| 4.7.1    | REVISION_REG Register (offset = FFFFEA00h) [reset = 4E840102h]            | 248        |
| 4.7.2    | ENDIAN_REG Register (offset = FFFFEA20h) [reset = 0h]                     | 249        |
| 4.7.3    | KICK_REG0 Register (offset = FFFFEA38h) [reset = 0h]                      | 250        |
| 4.7.4    | KICK_REG1 Register (offset = FFFFEA3Ch) [reset = 0h]                      | 251        |
| 4.7.5    | ERR_RAW_STATUS_REG Register (offset = FFFFEAE0h) [reset = 0h]             | 252        |
| 4.7.6    | ERR_ENABLED_STATUS_REG Register (offset = FFFFEAE4h) [reset = 0h]         | 253        |
| 4.7.7    | ERR_ENABLE_REG Register (offset = FFFFEAE8h) [reset = 0h]                 | 254        |
| 4.7.8    | ERR_ENABLE_CLR_REG Register (offset = FFFFEAECh) [reset = 0h]             | 255        |

|          |                                                                                    |            |
|----------|------------------------------------------------------------------------------------|------------|
| 4.7.9    | FAULT_ADDRESS_REG Register (offset = FFFFEAF4h) [reset = 0h]                       | 256        |
| 4.7.10   | FAULT_STATUS_REG Register (offset = FFFFEAF8h) [reset = 0h]                        | 257        |
| 4.7.11   | FAULT_CLEAR_REG Register (offset = FFFFEAFCh) [reset = 0h]                         | 258        |
| 4.7.12   | PINMMR0 to PINMMR47 Register (offset = FFFFEBC10h to FFFFEBCCh) [reset = 1010101h] | 259        |
| 4.8      | Output Multiplexing and Control                                                    | 260        |
| <b>5</b> | <b>F021 Flash Module Controller</b>                                                | <b>263</b> |
| 5.1      | Overview                                                                           | 264        |
| 5.1.1    | Features                                                                           | 264        |
| 5.1.2    | Definition of Terms                                                                | 264        |
| 5.1.3    | F021 Flash Tools                                                                   | 265        |
| 5.2      | Default Flash Configuration                                                        | 265        |
| 5.3      | SECEDED                                                                            | 266        |
| 5.3.1    | SECEDED Initialization                                                             | 266        |
| 5.3.2    | ECC Encoding                                                                       | 267        |
| 5.3.3    | Syndrom Table: Decode to Bit in Error                                              | 268        |
| 5.3.4    | Syndrom Table: An Alternate Method                                                 | 269        |
| 5.4      | Memory Map                                                                         | 270        |
| 5.4.1    | Location of Flash ECC bits                                                         | 270        |

| <b>24</b> | <b>High-End Timer Transfer Unit (HTU) Module</b>            | <b>1165</b> |
| 24.1      | Overview                                                    | 1166        |
| 24.1.1    | Features                                                    | 1166        |
| 24.2      | Module Operation                                            | 1167        |
| 24.2.1    | Data Transfers between Main RAM and NHET RAM                | 1169        |
| 24.2.2    | Arbitration of HTU Elements and Frames                      | 1174        |
| 24.2.3    | Conditions for Frame Transfer Interruption                  | 1174        |
| 24.2.4    | HTU Overload and Request Lost Detection                     | 1175        |
| 24.2.5    | Memory Protection                                           | 1177        |
| 24.2.6    | Control Packet RAM Parity Checking                          | 1178        |
| 24.3      | Use Cases                                                   | 1180        |
| 24.3.1    | Example: Single Element Transfer with One Trigger Request   | 1180        |
| 24.3.2    | Example: Multiple Element Transfer with One Trigger Request | 1180        |
| 24.3.3    | Example: 64-Bit-Transfer of Control Field and Data Fields   | 1181        |
| 24.4      | Control Registers                                           | 1183        |
| 24.4.1    | Global Control Register (HTU GC)                            | 1184        |
| 24.4.2    | Control Packet Enable Register (HTU CPENA)                  | 1185        |
| 24.4.3    | Control Packet (CP) Busy Register 0 (HTU BUSY0)             | 1186        |
| 24.4.4    | Control Packet (CP) Busy Register 1 (HTU BUSY1)             | 1187        |
| 24.4.5    | Control Packet (CP) Busy Register 2 (HTU BUSY2)             | 1187        |
| 24.4.6    | Control Packet (CP) Busy Register 3 (HTU BUSY3)             | 1188        |
| 24.4.7    | Active Control Packet and Error Register (HTU ACPE)         | 1188        |
| 24.4.8    | Request Lost and Bus Error Control Register (HTU RLBECTRL)  | 1190        |
| 24.4.9    | Buffer Full Interrupt Enable Set Register (HTU BFINTS)      | 1191        |
| 24.4.10   | Buffer Full Interrupt Enable Clear Register (HTU BFINTC)    | 1191        |
| 24.4.11   | Interrupt Mapping Register (HTU INTMAP)                     | 1192        |
| 24.4.12   | Interrupt Offset Register 0 (HTU INTOFF0)                   | 1193        |
| 24.4.13   | Interrupt Offset Register 1 (HTU INTOFF1)                   | 1194        |
| 24.4.14   | Buffer Initialization Mode Register (HTU BIM)               | 1195        |
| 24.4.15   | Request Lost Flag Register (HTU RLOSTFL)                    | 1197        |
| 24.4.16   | Buffer Full Interrupt Flag Register (HTU BFINTFL)           | 1197        |
| 24.4.17   | BER Interrupt Flag Register (HTU BERINTFL)                  | 1198        |

|           |                                                                            |             |
|-----------|----------------------------------------------------------------------------|-------------|
| 24.4.18   | Memory Protection 1 Start Address Register (HTU MP1S)                      | 1199        |
| 24.4.19   | Memory Protection 1 End Address Register (HTU MP1E)                        | 1199        |
| 24.4.20   | Debug Control Register (HTU DCTRL)                                         | 1200        |
| 24.4.21   | Watch Point Register (HTU WPR)                                             | 1201        |
| 24.4.22   | Watch Mask Register (HTU WMR)                                              | 1201        |
| 24.4.23   | Module Identification Register (HTU ID)                                    | 1202        |
| 24.4.24   | Parity Control Register (HTU PCR)                                          | 1203        |
| 24.4.25   | Parity Address Register (HTU PAR)                                          | 1204        |
| 24.4.26   | Memory Protection Control and Status Register (HTU MPCS)                   | 1205        |
| 24.4.27   | Memory Protection Start Address Register 0 (HTU MP0S)                      | 1207        |
| 24.4.28   | Memory Protection End Address Register (HTU MP0E)                          | 1207        |
| 24.5      | Double Control Packet Configuration Memory                                 | 1208        |
| 24.5.1    | Initial Full Address A Register (HTU IFADDRA)                              | 1209        |
| 24.5.2    | Initial Full Address B Register (HTU IFADDRB)                              | 1209        |
| 24.5.3    | Initial NHET Address and Control Register (HTU IHADDRCT)                   | 1210        |
| 24.5.4    | Initial Transfer Count Register (HTU ITCOUNT)                              | 1211        |
| 24.5.5    | Current Full Address A Register (HTU CFADDRA)                              | 1212        |
| 24.5.6    | Current Full Address B Register (HTU CFADDRB)                              | 1213        |
| 24.5.7    | Current Frame Count Register (HTU CFCOUNT)                                 | 1214        |
| 24.6      | Examples                                                                   | 1215        |
| 24.6.1    | Application Examples for Setting the Transfer Modes of CP A and B of a DCP | 1215        |
| 24.6.2    | Software Example Sequence Assuming Circular Mode for Both CP A and B       | 1215        |
| 24.6.3    | Example of an Interrupt Dispatch Flow for a Request Lost Interrupt         | 1216        |
| <b>25</b> | <b>General-Purpose Input/Output (GIO) Module</b>                           | <b>1217</b> |
| 25.1      | Overview                                                                   | 1218        |
| 25.2      | Quick Start Guide                                                          | 1219        |
| 25.3      | Functional Description of GIO Module                                       | 1221        |
| 25.3.1    | I/O Functions                                                              | 1221        |
| 25.3.2    | Interrupt Function                                                         | 1221        |
| 25.3.3    | GIO Block Diagram                                                          | 1222        |
| 25.4      | Device Modes of Operation                                                  | 1223        |
| 25.4.1    | Emulation Mode                                                             | 1223        |
| 25.4.2    | Power-Down Mode (Low-Power Mode)                                           | 1223        |
| 25.5      | GIO Control Registers                                                      | 1224        |
| 25.5.1    | GIO Global Control Register (GIOGCR0)                                      | 1225        |
| 25.5.2    | GIO Interrupt Detect Register (GIOINTDET)                                  | 1226        |
| 25.5.3    | GIO Interrupt Polarity Register (GIOPOL)                                   | 1227        |
| 25.5.4    | GIO Interrupt Enable Registers (GIOENASET and GIOENACLR)                   | 1228        |
| 25.5.5    | GIO Interrupt Priority Registers (GIOLVLSET and GIOLVLCLR)                 | 1230        |
| 25.5.6    | GIO Interrupt Flag Register (GIOFLG)                                       | 1233        |
| 25.5.7    | GIO Offset Register 1 (GIOOFF1)                                            | 1234        |
| 25.5.8    | GIO Offset B Register (GIOOFF2)                                            | 1235        |
| 25.5.9    | GIO Emulation A Register (GIOEMU1)                                         | 1236        |
| 25.5.10   | GIO Emulation B Register (GIOEMU2)                                         | 1237        |
| 25.5.11   | GIO Data Direction Registers [A-H][7:0] (IODIR[A-H][7:0])                  | 1238        |
| 25.5.12   | GIO Data Input Registers [A-H][7:0] (IODIN[A-H][7:0])                      | 1238        |
| 25.5.13   | GIO Data Output Registers [A-H][7:0] (IODOUT[A-H][7:0])                    | 1239        |
| 25.5.14   | GIO Data Set Register [A-H][7:0] (IODSET[A-H][7:0])                        | 1239        |
| 25.5.15   | GIO Data Clear Registers [A-H][7:0] (IODCLR[A-H][7:0])                     | 1240        |
| 25.5.16   | GIO Open Drain Register [A-H][7:0] (IOPDR[A-H][7:0])                       | 1240        |
| 25.5.17   | GIO Pull Disable Registers [A-H][7:0] (IOPULDIS[A-H][7:0])                 | 1241        |
| 25.5.18   | GIO Pull Select Register [A-H][7:0] (IOPSL[A-H][7:0])                      | 1241        |
| 25.6      | I/O Control Summary                                                        | 1242        |

|           |                                                        |             |
|-----------|--------------------------------------------------------|-------------|

| 32.4.14 | MDIO User PHY Select Register 1 (USERPHYSEL1) .....                                     | 1865 |
| 32.5    | EMAC Module Registers .....                                                             | 1866 |
| 32.5.1  | Transmit Revision ID Register (TXREVID) .....                                           | 1869 |
| 32.5.2  | Transmit Control Register (TXCONTROL) .....                                             | 1869 |
| 32.5.3  | Transmit Teardown Register (TXTEARDOWN) .....                                           | 1870 |
| 32.5.4  | Receive Revision ID Register (RXREVID) .....                                            | 1870 |
| 32.5.5  | Receive Control Register (RXCONTROL) .....                                              | 1871 |
| 32.5.6  | Receive Teardown Register (RXTEARDOWN) .....                                            | 1871 |
| 32.5.7  | Transmit Interrupt Status (Unmasked) Register (TXINTSTATRAW) .....                      | 1872 |

|           |                                                                                |             |
|-----------|--------------------------------------------------------------------------------|-------------|
| 32.5.8    | Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED)                  | 1873        |
| 32.5.9    | Transmit Interrupt Mask Set Register (TXINTMASKSET)                            | 1874        |
| 32.5.10   | Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR)                        | 1875        |
| 32.5.11   | MAC Input Vector Register (MACINVECTOR)                                        | 1876        |
| 32.5.12   | MAC End Of Interrupt Vector Register (MACEOIVECTOR)                            | 1877        |
| 32.5.13   | Receive Interrupt Status (Unmasked) Register (RXINTSTATRAW)                    | 1878        |
| 32.5.14   | Receive Interrupt Status (Masked) Register (RXINTSTATMASKED)                   | 1879        |
| 32.5.15   | Receive Interrupt Mask Set Register (RXINTMASKSET)                             | 1880        |
| 32.5.16   | Receive Interrupt Mask Clear Register (RXINTMASKCLEAR)                         | 1881        |
| 32.5.17   | MAC Interrupt Status (Unmasked) Register (MACINTSTATRAW)                       | 1882        |
| 32.5.18   | MAC Interrupt Status (Masked) Register (MACINTSTATMASKED)                      | 1882        |
| 32.5.19   | MAC Interrupt Mask Set Register (MACINTMASKSET)                                | 1883        |
| 32.5.20   | MAC Interrupt Mask Clear Register (MACINTMASKCLEAR)                            | 1883        |
| 32.5.21   | Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE)  | 1884        |
| 32.5.22   | Receive Unicast Enable Set Register (RXUNICASTSET)                             | 1886        |
| 32.5.23   | Receive Unicast Clear Register (RXUNICASTCLEAR)                                | 1887        |
| 32.5.24   | Receive Maximum Length Register (RXMAXLEN)                                     | 1887        |
| 32.5.25   | Receive Buffer Offset Register (RXBUFFEROFFSET)                                | 1888        |
| 32.5.26   | Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)       | 1888        |
| 32.5.27   | Receive Channel Flow Control Threshold Registers (RX0FLOWTHRESH-RX7FLOWTHRESH) | 1889        |
| 32.5.28   | Receive Channel Free Buffer Count Registers (RX0FREEBUFFER-RX7FREEBUFFER)      | 1889        |
| 32.5.29   | MAC Control Register (MACCONTROL)                                              | 1890        |
| 32.5.30   | MAC Status Register (MACSTATUS)                                                | 1892        |
| 32.5.31   | Emulation Control Register (EMCONTROL)                                         | 1894        |
| 32.5.32   | FIFO Control Register (FIFOCONTROL)                                            | 1894        |
| 32.5.33   | MAC Configuration Register (MACCONFIG)                                         | 1895        |
| 32.5.34   | Soft Reset Register (SOFTRESET)                                                | 1895        |
| 32.5.35   | MAC Source Address Low Bytes Register (MACSRCADDRLO)                           | 1896        |
| 32.5.36   | MAC Source Address High Bytes Register (MACSRCADDRHI)                          | 1896        |
| 32.5.37   | MAC Hash Address Register 1 (MACHASH1)                                         | 1897        |
| 32.5.38   | MAC Hash Address Register 2 (MACHASH2)                                         | 1897        |
| 32.5.39   | Back Off Test Register (BOFFTEST)                                              | 1898        |
| 32.5.40   | Transmit Pacing Algorithm Test Register (TPACETEST)                            | 1898        |
| 32.5.41   | Receive Pause Timer Register (RXPAUSE)                                         | 1899        |
| 32.5.42   | Transmit Pause Timer Register (TXPAUSE)                                        | 1899        |
| 32.5.43   | MAC Address Low Bytes Register (MACADDRLO)                                     | 1900        |
| 32.5.44   | MAC Address High Bytes Register (MACADDRHI)                                    | 1901        |
| 32.5.45   | MAC Index Register (MACINDEX)                                                  | 1901        |
| 32.5.46   | Transmit Channel DMA Head Descriptor Pointer Registers (TX0HDP-TX7HDP)         | 1902        |
| 32.5.47   | Receive Channel DMA Head Descriptor Pointer Registers (RX0HDP-RX7HDP)          | 1902        |
| 32.5.48   | Transmit Channel Completion Pointer Registers (TX0CP-TX7CP)                    | 1903        |
| 32.5.49   | Receive Channel Completion Pointer Registers (RX0CP-RX7CP)                     | 1903        |

| 19-18. | Action-Qualifier Submodule Inputs and Outputs .....                                                                | 720 |
| 19-19. | Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs .....                                              | 721 |
| 19-20. | Up-Down-Count Mode Symmetrical Waveform .....                                                                      | 724 |
| 19-21. | Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB—Active High.....             | 725 |
| 19-22. | Up, Single Edge Asymmetric Waveform With Independent Modulation on EPWMxA and EPWMxB—Active Low .....              | 727 |
| 19-23. | Up-Count, Pulse Placement Asymmetric Waveform With Independent Modulation on EPWMxA .....                          | 728 |
| 19-24. | Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Active Low .....   | 730 |
| 19-25. | Up-Down-Count, Dual Edge Symmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Complementary..... | 731 |
| 19-26. | Up-Down-Count, Dual Edge Asymmetric Waveform, With Independent Modulation on EPWMxA—Active Low.....                | 732 |
| 19-27. | Dead_Band Submodule.....                                                                                           | 733 |
| 19-28. | Configuration Options for the Dead-Band Submodule .....                                                            | 734 |
| 19-29. | Dead-Band Waveforms for Typical Cases (0% < Duty < 100%) .....                                                     | 736 |
| 19-30. | PWM-Chopper Submodule .....                                                                                        | 738 |
| 19-31. | PWM-Chopper Submodule Operational Details .....                                                                    | 739 |
| 19-32. | Simple PWM-Chopper Submodule Waveforms Showing Chopping Action Only .....                                          | 739 |
| 19-33. | PWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses.....                      | 740 |
| 19-34. | PWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses .....            | 741 |
| 19-35. | Trip-Zone Submodule .....                                                                                          | 742 |
| 19-36. | Trip-Zone Submodule Mode Control Logic .....                                                                       | 746 |
| 19-37. | Trip-Zone Submodule Interrupt Logic .....                                                                          | 747 |
| 19-38. | Event-Trigger Submodule.....                                                                                       | 748 |
| 19-39. | Event-Trigger Submodule Inter-Connectivity of ADC Start of Conversion .....                                        | 749 |
| 19-40. | Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs .....                                           | 750 |
| 19-41. | Event-Trigger Interrupt Generator .....                                                                            | 751 |
| 19-42. | Event-Trigger SOCA Pulse Generator .....                                                                           | 752 |
| 19-43. | Event-Trigger SOCB Pulse Generator .....                                                                           | 752 |
| 19-44. | Digital-Compare Submodule High-Level Block Diagram .....                                                           | 753 |

|                                                                                                     |     |
|-----------------------------------------------------------------------------------------------------|-----|
| 19-45. DCAEVT1 Event Triggering .....                                                               | 755 |
| 19-46. DCAEVT2 Event Triggering .....                                                               | 756 |
| 19-47. DCBEVT1 Event Triggering .....                                                               | 756 |
| 19-48. DCBEVT2 Event Triggering .....                                                               | 757 |
| 19-49. Event Filtering .....                                                                        | 758 |
| 19-50. Blanking Window Timing Diagram .....                                                         | 758 |
| 19-51. Simplified ePWM Module .....                                                                 | 760 |
| 19-52. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave .....                      | 761 |
| 19-53. Control of Four Buck Stages. Here $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$ ..... | 762 |
| 19-54. Buck Waveforms for (Note: Only three bucks shown here) .....                                 | 763 |
| 19-55. Control of Four Buck Stages. (Note: $F_{PWM2} = N \times F_{PWM1}$ ) .....                   | 765 |
| 19-56. Buck Waveforms for (Note: $F_{PWM2} = F_{PWM1}$ ) .....                                      | 766 |
| 19-57. Control of Two Half-H Bridge Stages ( $F_{PWM2} = N \times F_{PWM1}$ ) .....                 | 768 |
| 19-58. Half-H Bridge Waveforms for (Note: Here $F_{PWM2} = F_{PWM1}$ ) .....                        | 769 |
| 19-59. Control of Dual 3-Phase Inverter Stages as Is Commonly Used in Motor Control .....           | 771 |
| 19-60. 3-Phase Inverter Waveforms for (Only One Inverter Shown) .....                               | 772 |
| 19-61. Configuring Two PWM Modules for Phase Control .....                                          | 773 |
| 19-62. Timing Waveforms Associated With Phase Control Between 2 Modules .....                       | 774 |
| 19-63. TBSTS Register .....                                                                         | 776 |
| 19-64. TBCTL Register .....                                                                         | 777 |
| 19-65. TBPHS Register .....                                                                         | 779 |
| 19-66. TBPRD Register .....                                                                         | 780 |
| 19-67. TBCTR Register .....                                                                         | 781 |
| 19-68. CMPCTL Register .....                                                                        | 782 |
| 19-69. CMPA Register .....                                                                          | 784 |
| 19-70. AQCTLA Register .....                                                                        | 785 |
| 19-71. CMPB Register .....                                                                          | 787 |
| 19-72. AQSFRC Register .....                                                                        | 788 |
| 19-73. AQCTLB Register .....                                                                        | 789 |
| 19-74. DBCTL Register .....                                                                         | 791 |
| 19-75. AQCSFRC Register .....                                                                       | 793 |
| 19-76. DBFED Register .....                                                                         | 794 |
| 19-77. DBRED Register .....                                                                         | 795 |
| 19-78. TZDCSEL Register .....                                                                       | 796 |
| 19-79. TZSEL Register .....                                                                         | 797 |
| 19-80. TZEINT Register .....                                                                        | 799 |
| 19-81. TZCTL Register .....                                                                         | 800 |
| 19-82. TZCLR Register .....                                                                         | 801 |
| 19-83. TZFLG Register .....                                                                         | 802 |
| 19-84. ETSEL Register .....                                                                         | 803 |
| 19-85. TZFRC Register .....                                                                         | 805 |
| 19-86. ETFLG Register .....                                                                         | 806 |
| 19-87. ETPS Register .....                                                                          | 807 |
| 19-88. ETFRC Register .....                                                                         | 809 |
| 19-89. ETCLR Register .....                                                                         | 810 |
| 19-90. PCCTL Register .....                                                                         | 811 |
| 19-91. DCACTL Register .....                                                                        | 812 |
| 19-92. DCTRIPSEL Register .....                                                                     | 813 |
| 19-93. DCFCTL Register .....                                                                        | 814 |

|                                                                                                   |     |
|---------------------------------------------------------------------------------------------------|-----|
| 19-94. DCBCTL Register .....                                                                      | 815 |
| 19-95. DCOFFSET Register .....                                                                    | 816 |
| 19-96. DCCAPCTL Register .....                                                                    | 817 |
| 19-97. DCFWINDOW Register .....                                                                   | 818 |
| 19-98. DCOFFSETCNT Register .....                                                                 | 819 |
| 19-99. DCCAP Register .....                                                                       | 820 |
| 19-100. DCFWINDOWCNT Register .....                                                               | 821 |
| 20-1. Capture and APWM Modes of Operation.....                                                    | 824 |
| 20-2. Capture Function Diagram.....                                                               | 825 |
| 20-3. Event Prescale Control.....                                                                 | 826 |
| 20-4. Prescale Function Waveforms .....                                                           | 826 |
| 20-5. Details of the Continuous/One-shot Block .....                                              | 827 |
| 20-6. Details of the Counter and Synchronization Block .....                                      | 828 |
| 20-7. Interrupts in eCAP Module.....                                                              | 829 |
| 20-8. PWM Waveform Details Of APWM Mode Operation.....                                            | 830 |
| 20-9. TSCTR Register.....                                                                         | 832 |
| 20-10. CTRPHS Register.....                                                                       | 833 |
| 20-11. CAP1 Register.....                                                                         | 834 |
| 20-12. CAP2 Register.....                                                                         | 835 |
| 20-13. CAP3 Register.....                                                                         | 836 |
| 20-14. CAP4 Register.....                                                                         | 837 |
| 20-15. ECCTL2 Register .....                                                                      | 838 |
| 20-16. ECCTL1 Register .....                                                                      | 840 |
| 20-17. ECFLG Register.....                                                                        | 842 |
| 20-18. ECEINT Register.....                                                                       | 843 |
| 20-19. ECFRC Register .....                                                                       | 844 |
| 20-20. ECCLR Register .....                                                                       | 845 |
| 20-21. Capture Sequence for Absolute Time-stamp and Rising Edge Detect .....                      | 847 |
| 20-22. Capture Sequence for Absolute Time-stamp With Rising and Falling Edge Detect .....         | 849 |
| 20-23. Capture Sequence for Delta Mode Time-stamp and Rising Edge Detect .....                    | 851 |
| 20-24. Capture Sequence for Delta Mode Time-stamp With Rising and Falling Edge Detect .....       | 853 |
| 20-25. PWM Waveform Details of APWM Mode Operation .....                                          | 855 |
| 21-1. Optical Encoder Disk .....                                                                  | 857 |
| 21-2. QEP Encoder Output Signal for Forward/Reverse Movement.....                                 | 857 |
| 21-3. Index Pulse Example .....                                                                   | 858 |
| 21-4. Functional Block Diagram of the eQEP Peripheral .....                                       | 860 |
| 21-5. Functional Block Diagram of Decoder Unit.....                                               | 862 |
| 21-6. Quadrature Decoder State Machine.....                                                       | 864 |
| 21-7. Quadrature-clock and Direction Decoding.....                                                | 864 |
| 21-8. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOSMAX = 3999 or 0xF9F) ..... | 866 |
| 21-9. Position Counter Underflow/Overflow (QPOSMAX = 4) .....                                     | 867 |
| 21-10. Software Index Marker for 1000-line Encoder (QEPCTL[IEL] = 1).....                         | 869 |
| 21-11. Strobe Event Latch (QEPCTL[SEL] = 1).....                                                  | 869 |
| 21-12. eQEP Position-compare Unit.....                                                            | 870 |
| 21-13. eQEP Position-compare Event Generation Points .....                                        | 871 |
| 21-14. eQEP Position-compare Sync Output Pulse Stretcher .....                                    | 871 |
| 21-15. eQEP Edge Capture Unit .....                                                               | 873 |
| 21-16. Unit Position Event for Low Speed Measurement (QCAPCTL[UPPS] = 0010).....                  | 873 |
| 21-17. eQEP Edge Capture Unit - Timing Details .....                                              | 874 |

|                                                                               |     |
|-------------------------------------------------------------------------------|-----|
| 21-18. eQEP Watchdog Timer.....                                               | 875 |
| 21-19. eQEP Unit Time Base.....                                               | 875 |
| 21-20. EQEP Interrupt Generation.....                                         | 876 |
| 21-21. QPOSCNT Register.....                                                  | 878 |
| 21-22. QPOSINIT Register.....                                                 | 879 |
| 21-23. QPOSMAX Register.....                                                  | 880 |
| 21-24. QPOSCMP Register.....                                                  | 881 |
| 21-25. QPOSILAT Register.....                                                 | 882 |
| 21-26. QPOSSLAT Register.....                                                 | 883 |
| 21-27. QPOSLAT Register.....                                                  | 884 |
| 21-28. QUTMR Register.....                                                    | 885 |
| 21-29. QUPRD Register.....                                                    | 886 |
| 21-30. QWDPRD Register.....                                                   | 887 |
| 21-31. QWDTMR Register.....                                                   | 888 |
| 21-32. QEPCTL Register.....                                                   | 889 |
| 21-33. QDECCTL Register.....                                                  | 891 |
| 21-34. QPOSCCTL Register.....                                                 | 892 |
| 21-35. QCAPCTL Register.....                                                  | 893 |
| 21-36. QFLG Register.....                                                     | 894 |
| 21-37. QEINT Register.....                                                    | 896 |
| 21-38. QFRC Register.....                                                     | 897 |
| 21-39. QCLR Register.....                                                     | 898 |
| 21-40. QCTMR Register.....                                                    | 900 |
| 21-41. QEPSTS Register.....                                                   | 901 |
| 21-42. QCTMRLAT Register.....                                                 | 902 |
| 21-43. QCPRD Register.....                                                    | 903 |
| 21-44. QCPRDLAT Register.....                                                 | 904 |
| 22-1. Channel Assignments of Two ADC Cores.....                               | 906 |
| 22-2. ADC Block Diagram.....                                                  | 907 |
| 22-3. FIFO Implementation.....                                                | 912 |
| 22-4. Format of Conversion Result Read from FIFO, 12-bit ADC.....             | 913 |
| 22-5. Format of Conversion Result Read from FIFO, 10-bit ADC.....             | 913 |
| 22-6. ADC Memory Mapping.....                                                 | 914 |
| 22-7. Format of Conversion Result Directly Read from ADC RAM, 12-bit ADC..... | 914 |
| 22-8. Format of Conversion Result Directly Read from ADC RAM, 10-bit ADC..... | 914 |
| 22-9. Conversion Results Storage.....                                         | 915 |
| 22-10. ADC Groups' Operating Mode Control and Status Registers.....           | 917 |
| 22-11. Example Look-Up Table Entry.....                                       | 919 |
| 22-12. Group1 Enhanced Channel Selection Mode Example.....                    | 920 |
| 22-13. Self-Test and Calibration Logic.....                                   | 928 |
| 22-14. Mid-point Value Calculation.....                                       | 931 |
| 22-15. Self-Test and Calibration Logic.....                                   | 932 |
| 22-16. Timing for Self-Test Mode.....                                         | 933 |
| 22-17. Timing for Sample Capacitor Discharge Mode.....                        | 934 |
| 22-18. ADC Memory Map in Parity Test Mode.....                                | 936 |
| 22-19. GPIO Functionality of ADxEVT.....                                      | 936 |
| 22-20. ADRSTCR Register.....                                                  | 940 |
| 22-21. ADOPMODECR Register.....                                               | 941 |
| 22-22. ADCLOCKCR Register.....                                                | 943 |

|                                                  |      |
|--------------------------------------------------|------|
| 22-23. ADCALCR Register .....                    | 944  |
| 22-24. ADEVMODECR Register .....                 | 946  |
| 22-25. ADG1MODECR Register .....                 | 948  |
| 22-26. ADG2MODECR Register .....                 | 951  |
| 22-27. ADEVSRC Register.....                     | 954  |
| 22-28. ADG1SRC Register.....                     | 955  |
| 22-29. ADG2SRC Register.....                     | 956  |
| 22-30. ADEVINTENA Register .....                 | 957  |
| 22-31. ADG1INTENA Register .....                 | 958  |
| 22-32. ADG2INTENA Register .....                 | 959  |
| 22-33. ADEVINTFLG Register.....                  | 960  |
| 22-34. ADG1INTFLG Register.....                  | 961  |
| 22-35. ADG2INTFLG Register.....                  | 962  |
| 22-36. ADEVTHRINTCR Register .....               | 963  |
| 22-37. ADG1THRINTCR Register .....               | 964  |
| 22-38. ADG2THRINTCR Register .....               | 965  |
| 22-39. ADEVDMACR Register .....                  | 966  |
| 22-40. ADG1DMACR Register .....                  | 968  |
| 22-41. ADG2DMACR Register .....                  | 970  |
| 22-42. ADBNDCR Register .....                    | 972  |
| 22-43. ADBNDEND Register .....                   | 973  |
| 22-44. ADEVSAMP Register.....                    | 974  |
| 22-45. ADG1SAMP Register.....                    | 975  |
| 22-46. ADG2SAMP Register.....                    | 976  |
| 22-47. ADEVSR Register.....                      | 977  |
| 22-48. ADG1SR Register.....                      | 978  |
| 22-49. ADG2SR Register.....                      | 979  |
| 22-50. ADEVSEL Register .....                    | 980  |
| 22-51. ADG1SEL Register .....                    | 981  |
| 22-52. ADG2SEL Register .....                    | 982  |
| 22-53. ADCALR Register.....                      | 983  |
| 22-54. ADSMSTATE Register .....                  | 984  |
| 22-55. ADLASTCONV Register .....                 | 985  |
| 22-56. ADEVBUFFER0 to ADEVBUFFER7 Register ..... | 986  |
| 22-57. ADG1BUFFER0 to ADG1BUFFER7 Register ..... | 987  |
| 22-58. ADG2BUFFER0 to ADG2BUFFER7 Register ..... | 988  |
| 22-59. ADEVEMUBUFFER Register .....              | 989  |
| 22-60. ADG1EMUBUFFER Register .....              | 990  |
| 22-61. ADG2EMUBUFFER Register .....              | 991  |
| 22-62. ADEVTDIR Register .....                   | 992  |
| 22-63. ADEVTOUT Register .....                   | 993  |
| 22-64. ADEVTIN Register .....                    | 994  |
| 22-65. ADEVTSET Register .....                   | 995  |
| 22-66. ADEVTCLR Register .....                   | 996  |
| 22-67. ADEVTPDR Register .....                   | 997  |
| 22-68. ADEVTPDIS Register .....                  | 998  |
| 22-69. ADEVTPSEL Register.....                   | 999  |
| 22-70. ADEVSAMPDISEN Register.....               | 1000 |
| 22-71. ADG1SAMPDISEN Register.....               | 1001 |

|                                                                 |      |

| 26-3. Transfer Unit .....                                                                                                                                                  | 1249 |
| 26-4. FlexRay Transfer Unit Operation Principle .....                                                                                                                      | 1250 |
| 26-5. FlexRay Transfer Unit Operation Principle for Transfer FSM (simplified) .....                                                                                        | 1251 |
| 26-6. FlexRay Transfer Unit Operation Principle for Event FSM (simplified) .....                                                                                           | 1252 |
| 26-7. Example: FTU Read Transfer of 6 Words .....                                                                                                                          | 1254 |
| 26-8. Example: FTU Write Transfer of 6 Words .....                                                                                                                         | 1254 |
| 26-9. Transfer Start Address to Message Buffer Number Assignment .....                                                                                                     | 1256 |
| 26-10. Structure of Communication Cycle .....                                                                                                                              | 1259 |
| 26-11. Configuration of NIT Start and Offset Correction Start .....                                                                                                        | 1260 |
| 26-12. Overall State Diagram of Communication Controller .....                                                                                                             | 1264 |
| 26-13. Structure of POC State WAKEUP .....                                                                                                                                 | 1268 |
| 26-14. Timing of Wake Up Pattern .....                                                                                                                                     | 1270 |
| 26-15. State Diagram Time-Triggered Startup .....                                                                                                                          | 1272 |
| 26-16. FIFO Status: Empty, Not Empty, and Overrun .....                                                                                                                    | 1282 |
| 26-17. Host Access to Message RAM .....                                                                                                                                    | 1285 |
| 26-18. Double Buffer Structure Input Buffer .....                                                                                                                          | 1286 |
| 26-19. Swapping of IBCM and IBCR Bits .....                                                                                                                                | 1286 |
| 26-20. Double Buffer Structure Output Buffer .....                                                                                                                         | 1287 |
| 26-21. Swapping of OBCM and OBCR Bits .....                                                                                                                                | 1288 |
| 26-22. Access to Transient Buffer RAMs .....                                                                                                                               | 1290 |
| 26-23. Configuration Example of Message Buffers in the Message RAM .....                                                                                                   | 1291 |
| 26-24. Header Section of Message Buffer in Message RAM .....                                                                                                               | 1292 |
| 26-25. Example Structure of Data Partition in Message RAM .....                                                                                                            | 1294 |
| 26-26. Parity Structure .....                                                                                                                                              | 1295 |
| 26-27. Parity Generation and Check .....                                                                                                                                   | 1296 |
| 26-28. Transfer Unit Interrupt Structure .....                                                                                                                             | 1299 |
| 26-29. Interrupt Structure .....                                                                                                                                           | 1301 |
| 26-30. Global Static Number 0 (GSN0) [offset_TU = 00h] .....                                                                                                               | 1305 |
| 26-31. Global Static Number 1 (GSN1) [offset_TU = 04h] .....                                                                                                               | 1305 |
| 26-32. Global Control Set (GCS) [offset_TU = 10h].....                                                                                                                     | 1306 |
| 26-33. Global Control Reset (GCR) [offset_TU = 14h] .....                                                                                                                  | 1306 |
| 26-34. Transfer Status Current Buffer (TSCB) [offset_TU = 18h] .....                                                                                                       | 1309 |
| 26-35. Last Transferred Buffer to Communication Controller (LTBCC) [offset_TU = 1Ch] .....                                                                                 | 1310 |
| 26-36. Last Transferred Buffer to System Memory (LTBSM) [offset_TU = 20h] .....                                                                                            | 1310 |
| 26-37. Transfer Base Address (TBA) [offset_TU = 24h] .....                                                                                                                 | 1311 |

|                                                                                              |      |

| 28-41. SPI Transmit Data Register 1 (SPIDAT1) [offset = 3Ch] .....                                   | 1561 |
| 28-42. SPI Receive Buffer Register (SPIBUF) [offset = 40h] .....                                     | 1562 |
| 28-43. SPI Emulation Register (SPIEMU) [offset = 44h] .....                                          | 1564 |
| 28-44. SPI Delay Register (SPIDELAY) [offset = 48h] .....                                            | 1564 |
| 28-45. Example: $t_{C2TDELAY} = 8 \text{ VCLK Cycles}$ .....                                         | 1566 |
| 28-46. Example: $t_{T2CDELAY} = 4 \text{ VCLK Cycles}$ .....                                         | 1566 |
| 28-47. Transmit-Data-Finished-to-ENA-Inactive-Timeout .....                                          | 1566 |
| 28-48. Chip-Select-Active-to-ENA-Signal-Active-Timeout .....                                         | 1566 |
| 28-49. SPI Default Chip Select Register (SPIDEF) [offset = 4Ch] .....                                | 1567 |
| 28-50. SPI Data Format Registers (SPIFMT[3:0]) [offset = 5Ch-50h] .....                              | 1568 |
| 28-51. Interrupt Vector 0 (NTVECT0) [offset = 60h] .....                                             | 1570 |
| 28-52. Interrupt Vector 1 (INTVECT1) [offset = 64h] .....                                            | 1571 |
| 28-53. Parallel/Modulo Mode Control Register (SPIPMCTRL) [offset = 6Ch] .....                        | 1572 |
| 28-54. Multi-buffer Mode Enable Register (MIBSPIE) [offset = 70h] .....                              | 1575 |
| 28-55. TG Interrupt Enable Set Register (TGITENST) [offset = 74h] .....                              | 1576 |
| 28-56. TG Interrupt Enable Clear Register (TGITENCR) [offset = 78h] .....                            | 1577 |
| 28-57. Transfer Group Interrupt Level Set Register (TGITLVST) [offset = 7Ch] .....                   | 1578 |
| 28-58. Transfer Group Interrupt Level Clear Register (TGITLVCR) [offset = 80h] .....                 | 1579 |
| 28-59. Transfer Group Interrupt Flag Register (TGINTFLG) [offset = 84h] .....                        | 1580 |
| 28-60. Tick Counter Operation .....                                                                  | 1581 |
| 28-61. Tick Count Register (TICKCNT) [offset = 90h] .....                                            | 1581 |
| 28-62. Last TG End Pointer (LTGPEND) [offset = 94h] .....                                            | 1582 |
| 28-63. MibSPI TG Control Registers (TGxCTRL) [offsets = 98h-D4h] .....                               | 1583 |
| 28-64. DMA Channel Control Register (DMAxCTRL) [offset = D8h-F4h] .....                              | 1586 |
| 28-65. DMAxCOUNT Register (ICOUNT) [offset = F8h-114h] .....                                         | 1588 |
| 28-66. DMA Large Count Register (DMACNTLEN) [offset = 118h] .....                                    | 1589 |
| 28-67. Multi-buffer RAM Uncorrectable Parity Error Control Register (UERRCTRL) [offset = 120h] ..... | 1589 |
| 28-68. Multi-buffer RAM Uncorrectable Parity Error Status Register (UERRSTAT) [offset = 124h] .....  | 1590 |
| 28-69. RXRAM Uncorrectable Parity Error Address Register (UERRADDR1) [offset = 128h] .....           | 1591 |
| 28-70. TXRAM Uncorrectable Parity Error Address Register (UERRADDR0) [offset = 12Ch] .....           | 1592 |
| 28-71. RXRAM Overrun Buffer Address Register (RXOVRN_BUF_ADDR) [offset = 130h] .....                 | 1593 |
| 28-72. I/O-Loopback Test Control Register (IOLPBKTSTCR) [offset = 134h] .....                        | 1594 |

|                                                                                                            |      |
|------------------------------------------------------------------------------------------------------------|------|
| 28-73. SPI Extended Prescale Register 1 (EXTENDED_PRESCALE1 for SPIFMT0 and SPIFMT1) [offset = 138h] ..... | 1596 |
| 28-74. SPI Extended Prescale Register 2 (EXTENDED_PRESCALE2 for SPIFMT2 and SPIFMT3) [offset = 13Ch] ..... | 1598 |
| 28-75. Multi-Buffer RAM Configuration .....                                                                | 1600 |
| 28-76. Multi-buffer RAM Transmit Data Register [offset = Base + 000-1FFh] .....                            | 1602 |
| 28-77. Multi-buffer RAM Receive Buffer Register [offset = RAM Base + 200-3FFh] .....                       | 1604 |
| 28-78. Memory Map for Parity Locations during Normal and Test Mode .....                                   | 1607 |
| 28-79. Example of Memory Mapped Parity Locations during Test Mode .....                                    | 1608 |
| 28-80. SPI/MibSPI Pins during Master mode 3-pin configuration .....                                        | 1609 |
| 28-81. SPI/MibSPI pins during Master mode 4-pin with $\overline{\text{SPISCS}}$ configuration. ....        | 1609 |
| 28-82. SPI/MibSPI pins during Master mode in 4pin with $\overline{\text{SPIENA}}$ configuration .....      | 1610 |
| 28-83. SPI/MibSPI pins during Master/Slave mode with 5-pin configuration .....                             | 1610 |
| 28-84. SPI/MibSPI pins during Slave mode 3-pin configuration .....                                         | 1611 |
| 28-85. SPI/MibSPI pins during Slave mode in 4pin with $\overline{\text{SPIENA}}$ configuration .....       | 1611 |
| 28-86. SPI/MibSPI pins during Slave mode in 5pin configuration - (Single Slave). ....                      | 1611 |
| 28-87. SPI/MibSPI pins during Slave mode in 5pin configuration - (Single/Multi Slave). ....                | 1611 |
| 29-1. Detailed SCI Block Diagram .....                                                                     | 1619 |
| 29-2. SCI/LIN Block Diagram .....                                                                          | 1620 |
| 29-3. Typical SCI Data Frame Formats .....                                                                 | 1621 |
| 29-4. Asynchronous Communication Bit Timing .....                                                          | 1622 |
| 29-5. Superfractional Divider Example .....                                                                | 1624 |
| 29-6. Idle-Line Multiprocessor Communication Format .....                                                  | 1626 |
| 29-7. Address-Bit Multiprocessor Communication Format .....                                                | 1626 |
| 29-8. Receive Buffers .....                                                                                | 1627 |
| 29-9. Transmit Buffers .....                                                                               | 1628 |
| 29-10. General Interrupt Scheme .....                                                                      | 1629 |
| 29-11. Interrupt Generation for Given Flags .....                                                          | 1630 |
| 29-12. LIN Protocol Message Frame Format: Master Header and Slave Response .....                           | 1637 |
| 29-13. Header 3 Fields: Synch Break, Synch, and ID .....                                                   | 1637 |
| 29-14. Response Format of LIN Message Frame .....                                                          | 1638 |
| 29-15. Message Header in Terms of $T_{\text{bit}}$ .....                                                   | 1641 |
| 29-16. ID Field .....                                                                                      | 1641 |
| 29-17. Measurements for Synchronization .....                                                              | 1643 |
| 29-18. Synchronization Validation Process and Baud Rate Adjustment .....                                   | 1644 |
| 29-19. Optional Embedded Checksum in Response for Extended Frames .....                                    | 1645 |
| 29-20. Checksum Compare and Send for Extended Frames .....                                                 | 1646 |
| 29-21. TXRX Error Detector .....                                                                           | 1648 |
| 29-22. Classic Checksum Generation at Transmitting Node .....                                              | 1649 |
| 29-23. LIN 2.0-Compliant Checksum Generation at Transmitting Node .....                                    | 1649 |
| 29-24. ID Reception, Filtering and Validation .....                                                        | 1651 |
| 29-25. LIN Message Frame Showing LIN Interrupt Timing and Sequence .....                                   | 1653 |

| 30-32. GPIO Functionality .....                                             | 1753 |
| 31-1. Multiple I2C Modules Connection Diagram .....                         | 1756 |
| 31-2. Simple I2C Block Diagram .....                                        | 1758 |
| 31-3. Clocking Diagram for the I2C Module .....                             | 1759 |
| 31-4. Bit Transfer on the I2C Bus .....                                     | 1760 |
| 31-5. I2C Module START and STOP Conditions .....                            | 1761 |
| 31-6. I2C Module Data Transfer .....                                        | 1761 |
| 31-7. I2C Module 7-Bit Addressing Format .....                              | 1762 |
| 31-8. I2C Module 10-bit Addressing Format .....                             | 1762 |
| 31-9. I2C Module 7-Bit Addressing Format with Repeated START .....          | 1762 |
| 31-10. I2C Module in Free Data Format .....                                 | 1763 |
| 31-11. Arbitration Procedure Between Two Master Transmitters .....          | 1766 |
| 31-12. Synchronization of Two I2C Clock Generators During Arbitration ..... | 1767 |
| 31-13. I2C Own Address Manager Register (I2COAR) [Offset = 00] .....        | 1772 |
| 31-14. I2C Interrupt Mask Register (I2CIMR) [Offset = 04h] .....            | 1773 |
| 31-15. I2C Status Register (I2CSR) [Offset = 08h] .....                     | 1774 |
| 31-16. I2C Clock Divider Low Register (I2CCKL) [Offset = 0Ch] .....         | 1777 |
| 31-17. I2C Clock Control High Register (I2CCKH) [Offset = 10h] .....        | 1777 |
| 31-18. I2C Data Count Register (I2CCNT) [Offset = 14h] .....                | 1778 |
| 31-19. I2C Data Receive Register (I2CDRR) [Offset = 18h] .....              | 1778 |
| 31-20. I2C Slave Address Register (I2CSAR) [Offset = 1Ch] .....             | 1779 |
| 31-21. I2C Data Transmit Register (I2CDXR) [Offset = 20h] .....             | 1779 |
| 31-22. I2C Mode Register (I2CMDR) [Offset = 24h] .....                      | 1780 |
| 31-23. Typical Timing Diagram of Repeat Mode .....                          | 1782 |
| 31-24. I2C Interrupt Vector Register (I2CIVR) [Offset = 28h] .....          | 1783 |
| 31-25. I2C Extended Mode Register (I2CEMDR) [Offset = 2Ch] .....            | 1784 |
| 31-26. I2C Prescale Register (I2CPSC) [Offset = 30h] .....                  | 1784 |
| 31-27. I2C Peripheral ID Register 1 (I2CPID1) [Offset = 34h] .....          | 1785 |
| 31-28. I2C Peripheral ID Register 2 (I2CPID2) [Offset = 38h] .....          | 1785 |
| 31-29. I2C DMA Control Register (I2CDMACR) [Offset = 3Ch] .....             | 1786 |
| 31-30. I2C Pin Function Register (I2CPFNC) [Offset = 48h] .....             | 1786 |
| 31-31. I2C Pin Direction Register (I2CPDIR) [Offset = 4Ch] .....            | 1787 |
| 31-32. I2C Data Input Register (I2CDIN) [Offset = 50h] .....                | 1787 |
| 31-33. I2C Data Output Register (I2CDOUT) [Offset 0x54] .....               | 1788 |
| 31-34. I2C Data Set Register (I2CDSET) [Offset = 58h] .....                 | 1788 |
| 31-35. I2C Data Clear Register (I2CDCLR) [Offset = 5Ch] .....               | 1789 |
| 31-36. I2C Pin Open Drain Register (I2CPDR) [Offset = 60h] .....            | 1789 |
| 31-37. I2C Pull Disable Register (I2CPDIS) [Offset = 64h] .....             | 1790 |
| 31-38. I2C Pull Select Register (I2CPSEL) [Offset = 68h] .....              | 1790 |

|                                                                                              |      |
|----------------------------------------------------------------------------------------------|------|
| 31-39. I2C Pins Slew Rate Select Register (I2CSRS) [Offset = 6Ch] .....                      | 1791 |
| 31-40. Difference between Normal Operation and Backward Compatibility Mode .....             | 1792 |
| 32-1. EMAC and MDIO Block Diagram.....                                                       | 1795 |
| 32-2. Ethernet Configuration—MII Connections.....                                            | 1798 |
| 32-3. Ethernet Configuration—RMII Connections.....                                           | 1799 |
| 32-4. Ethernet Frame Format .....                                                            | 1800 |
| 32-5. Basic Descriptor Format .....                                                          | 1802 |
| 32-6. Typical Descriptor Linked List.....                                                    | 1803 |
| 32-7. Transmit Buffer Descriptor Format .....                                                | 1806 |
| 32-8. Receive Buffer Descriptor Format.....                                                  | 1809 |
| 32-9. EMAC Control Module Block Diagram.....                                                 | 1813 |
| 32-10. MDIO Module Block Diagram.....                                                        | 1815 |
| 32-11. EMAC Module Block Diagram .....                                                       | 1819 |
| 32-12. EMAC Control Module Revision ID Register (REVID).....                                 | 1841 |
| 32-13. EMAC Control Module Software Reset Register (SOFTRESET) .....                         | 1841 |
| 32-14. EMAC Control Module Interrupt Control Register (INTCONTROL).....                      | 1842 |
| 32-15. EMAC Control Module Receive Threshold Interrupt Enable Register (C0RXTHRESHEN) .....  | 1843 |
| 32-16. EMAC Control Module Receive Interrupt Enable Register (C0RXEN) .....                  | 1844 |
| 32-17. EMAC Control Module Transmit Interrupt Enable Register (C0TXEN).....                  | 1845 |
| 32-18. EMAC Control Module Miscellaneous Interrupt Enable Register (C0MISCEN).....           | 1846 |
| 32-19. EMAC Control Module Receive Threshold Interrupt Status Register (C0RXTHRESHSTAT)..... | 1847 |
| 32-20. EMAC Control Module Receive Interrupt Status Register (C0RXSTAT).....                 | 1848 |
| 32-21. EMAC Control Module Transmit Interrupt Status Register (C0TXSTAT) .....               | 1849 |
| 32-22. EMAC Control Module Miscellaneous Interrupt Status Register (C0MISCSTAT) .....        | 1850 |
| 32-23. EMAC Control Module Receive Interrupts Per Millisecond Register (C0RXIMAX) .....      | 1851 |
| 32-24. EMAC Control Module Transmit Interrupts Per Millisecond Register (C0TXIMAX) .....     | 1852 |
| 32-25. MDIO Revision ID Register (REVID).....                                                | 1853 |
| 32-26. MDIO Control Register (CONTROL).....                                                  | 1854 |
| 32-27. PHY Acknowledge Status Register (ALIVE) .....                                         | 1855 |
| 32-28. PHY Link Status Register (LINK).....                                                  | 1855 |
| 32-29. MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW) .....              | 1856 |
| 32-30. MDIO Link Status Change Interrupt (Masked) Register (LINKINTMASKED) .....             | 1857 |
| 32-31. MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW).....            | 1858 |
| 32-32. MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED) .....          | 1859 |
| 32-33. MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET).....          | 1860 |
| 32-34. MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR) .....     | 1861 |
| 32-35. MDIO User Access Register 0 (USERACCESS0) .....                                       | 1862 |
| 32-36. MDIO User PHY Select Register 0 (USERPHYSEL0) .....                                   | 1863 |
| 32-37. MDIO User Access Register 1 (USERACCESS1) .....                                       | 1864 |
| 32-38. MDIO User PHY Select Register 1 (USERPHYSEL1) .....                                   | 1865 |
| 32-39. Transmit Revision ID Register (TXREVID).....                                          | 1869 |
| 32-40. Transmit Control Register (TXCONTROL) .....                                           | 1869 |
| 32-41. Transmit Teardown Register (TXTEARDOWN) .....                                         | 1870 |
| 32-42. Receive Revision ID Register (RXREVID) .....                                          | 1870 |
| 32-43. Receive Control Register (RXCONTROL) .....                                            | 1871 |
| 32-44. Receive Teardown Register (RXTEARDOWN) .....                                          | 1871 |
| 32-45. Transmit Interrupt Status (Unmasked) Register (TXINTSTATRAW) .....                    | 1872 |
| 32-46. Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED).....                    | 1873 |
| 32-47. Transmit Interrupt Mask Set Register (TXINTMASKSET) .....                             | 1874 |

|                                                                                            |      |
|--------------------------------------------------------------------------------------------|------|
| 32-48. Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR) .....                       | 1875 |
| 32-49. MAC Input Vector Register (MACINVECTOR) .....                                       | 1876 |
| 32-50. MAC End Of Interrupt Vector Register (MACEOIVECTOR) .....                           | 1877 |
| 32-51. Receive Interrupt Status (Unmasked) Register (RXINTSTATRAW) .....                   | 1878 |
| 32-52. Receive Interrupt Status (Masked) Register (RXINTSTATMASKED) .....                  | 1879 |
| 32-53. Receive Interrupt Mask Set Register (RXINTMASKSET) .....                            | 1880 |
| 32-54. Receive Interrupt Mask Clear Register (RXINTMASKCLEAR) .....                        | 1881 |
| 32-55. MAC Interrupt Status (Unmasked) Register (MACINTSTATRAW) .....                      | 1882 |
| 32-56. MAC Interrupt Status (Masked) Register (MACINTSTATMASKED) .....                     | 1882 |
| 32-57. MAC Interrupt Mask Set Register (MACINTMASKSET) .....                               | 1883 |
| 32-58. MAC Interrupt Mask Clear Register (MACINTMASKCLEAR) .....                           | 1883 |
| 32-59. Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE) ..... | 1884 |
| 32-60. Receive Unicast Enable Set Register (RXUNICASTSET) .....                            | 1886 |
| 32-61. Receive Unicast Clear Register (RXUNICASTCLEAR) .....                               | 1887 |
| 32-62. Receive Maximum Length Register (RXMAXLEN) .....                                    | 1887 |
| 32-63. Receive Buffer Offset Register (RXBUFFEROFFSET) .....                               | 1888 |
| 32-64. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH) .....      | 1888 |
| 32-65. Receive Channel <i>n</i> Flow Control Threshold Register (RX $n$ FLOWTHRESH) .....  | 1889 |
| 32-66. Receive Channel <i>n</i> Free Buffer Count Register (RX $n$ FREEBUFFER) .....       | 1889 |
| 32-67. MAC Control Register (MACCONTROL) .....                                             | 1890 |
| 32-68. MAC Status Register (MACSTATUS) .....                                               | 1892 |
| 32-69. Emulation Control Register (EMCONTROL) .....                                        | 1894 |
| 32-70. FIFO Control Register (FIFOCONTROL) .....                                           | 1894 |
| 32-71. MAC Configuration Register (MACCONFIG) .....                                        | 1895 |
| 32-72. Soft Reset Register (SOFTRESET) .....                                               | 1895 |
| 32-73. MAC Source Address Low Bytes Register (MACSRCADDRLO) .....                          | 1896 |
| 32-74. MAC Source Address High Bytes Register (MACSRCADDRHI) .....                         | 1896 |
| 32-75. MAC Hash Address Register 1 (MACHASH1) .....                                        | 1897 |
| 32-76. MAC Hash Address Register 2 (MACHASH2) .....                                        | 1897 |
| 32-77. Back Off Random Number Generator Test Register (BOFFTEST) .....                     | 1898 |
| 32-78. Transmit Pacing Algorithm Test Register (TPACETEST) .....                           | 1898 |
| 32-79. Receive Pause Timer Register (RXPAUSE) .....                                        | 1899 |
| 32-80. Transmit Pause Timer Register (TXPAUSE) .....                                       | 1899 |
| 32-81. MAC Address Low Bytes Register (MACADDRLO) .....                                    | 1900 |
| 32-82. MAC Address High Bytes Register (MACADDRHI) .....                                   | 1901 |
| 32-83. MAC Index Register (MACINDEX) .....                                                 | 1901 |
| 32-84. Transmit Channel <i>n</i> DMA Head Descriptor Pointer Register (TX $n$ HDP) .....   | 1902 |
| 32-85. Receive Channel <i>n</i> DMA Head Descriptor Pointer Register (RX $n$ HDP) .....    | 1902 |
| 32-86. Transmit Channel <i>n</i> Completion Pointer Register (TX $n$ CP) .....             | 1903 |
| 32-87. Receive Channel <i>n</i> Completion Pointer Register (RX $n$ CP) .....              | 1903 |

| 2-14. | DCC1 Counter 1 Clock / Signal Inputs .....                                                 | 128 |
| 2-15. | DCC2 Counter 0 Clock Inputs .....                                                          | 129 |
| 2-16. | DCC2 Counter 1 Clock / Signal Inputs .....                                                 | 129 |
| 2-17. | Primary System Control Registers.....                                                      | 130 |
| 2-18. | SYS Pin Control Register 1 (SYSPC1) Field Descriptions .....                               | 132 |
| 2-19. | SYS Pin Control Register 2 (SYSPC2) Field Descriptions .....                               | 132 |
| 2-20. | SYS Pin Control Register 3 (SYSPC3) Field Descriptions .....                               | 133 |
| 2-21. | SYS Pin Control Register 4 (SYSPC4) Field Descriptions .....                               | 133 |
| 2-22. | SYS Pin Control Register 5 (SYSPC5) Field Descriptions .....                               | 134 |
| 2-23. | SYS Pin Control Register 6 (SYSPC6) Field Descriptions .....                               | 134 |
| 2-24. | SYS Pin Control Register 7 (SYSPC7) Field Descriptions .....                               | 135 |
| 2-25. | SYS Pin Control Register 8 (SYSPC8) Field Descriptions .....                               | 135 |
| 2-26. | SYS Pin Control Register 9 (SYSPC9) Field Descriptions .....                               | 136 |
| 2-27. | Clock Source Disable Register (CSDIS) Field Descriptions.....                              | 137 |
| 2-28. | Clock Sources Table .....                                                                  | 137 |
| 2-29. | Clock Source Disable Set Register (CSDISSET) Field Descriptions .....                      | 138 |
| 2-30. | Clock Source Disable Clear Register (CSDISCLR) Field Descriptions .....                    | 139 |
| 2-31. | Clock Domain Disable Register (CDDIS) Field Descriptions.....                              | 140 |
| 2-32. | Clock Domain Disable Set Register (CDDISSET) Field Descriptions.....                       | 141 |
| 2-33. | Clock Domain Disable Clear Register (CDDISCLR) Field Descriptions .....                    | 143 |
| 2-34. | GCLK, HCLK, VCLK, and VCLK2 Source Register (GHVSR) Field Descriptions.....                | 145 |
| 2-35. | Peripheral Asynchronous Clock Source Register (VCLKASRC) Field Descriptions .....          | 146 |
| 2-36. | RTI Clock Source Register (RCLKSRC) Field Descriptions.....                                | 147 |
| 2-37. | Clock Source Valid Register (CSVSTAT) Field Descriptions .....                             | 148 |
| 2-38. | Memory Self-Test Global Control Register (MSTGCR) Field Descriptions.....                  | 149 |
| 2-39. | Memory Hardware Initialization Global Control Register (MINITGCR) Field Descriptions ..... | 150 |
| 2-40. | MBIST Controller/Memory Initialization Enable Register (MSINENA) Field Descriptions .....  | 151 |
| 2-41. | Memory Self-Test Fail Status Register (MSTFAIL) Field Descriptions .....                   | 152 |
| 2-42. | MSTC Global Status Register (MSTCGSTAT) Field Descriptions .....                           | 153 |
| 2-43. | Memory Hardware Initialization Status Register (MINISTAT) Field Descriptions .....         | 154 |
| 2-44. | PLL Control Register 1 (PLLCTL1) Field Descriptions.....                                   | 155 |
| 2-45. | PLL Control Register 2 (PLLCTL2) Field Descriptions.....                                   | 156 |
| 2-46. | SYS Pin Control Register 10 (SYSPC10) Field Descriptions .....                             | 157 |
| 2-47. | Die Identification Register, Lower Word (DIEIDL) Field Descriptions .....                  | 158 |

|       |                                                                                             |            |
|-------|---------------------------------------------------------------------------------------------|------------|
| 2-48. | Die Identification Register, Upper Word (DIEIDH) Field Descriptions .....                   | 158        |
| 2-49. | LPO/Clock Monitor Control Register (LPOMONCTL) Field Descriptions.....                      | 159        |
| 2-50. | Clock Test Register (CLKTEST) Field Descriptions .....                                      | 162        |
| 2-51. | DFT Control Register (DFTCTRLREG) Field Descriptions .....                                  | 164        |
| 2-52. | DFT Control Register 2 (DFTCTRLREG2) Field Descriptions .....                               | 165        |
| 2-53. | General Purpose Register (GPREG1) Field Descriptions .....                                  | 166        |
| 2-54. | Imprecise Fault Status Register (IMPFSTS) Field Descriptions .....                          | 168        |
| 2-55. | Imprecise Fault Write Address Register (IMPFTADD) Field Descriptions.....                   | 169        |
| 2-56. | System Software Interrupt Request 1 Register (SSIR1) Field Descriptions .....               | 170        |
| 2-57. | System Software Interrupt Request 2 Register (SSIR2) Field Descriptions .....               | 170        |
| 2-58. | System Software Interrupt Request 3 Register (SSIR3) Field Descriptions .....               | 171        |
| 2-59. | System Software Interrupt Request 4 Register (SSIR4) Field Descriptions .....               | 171        |
| 2-60. | RAM Control Register (RAMGCR) Field Descriptions .....                                      | 172        |
| 2-61. | Bus Matrix Module Control Register 1 (BMMCR) Field Descriptions .....                       | 173        |
| 2-62. | CPU Reset Control Register (CPURSTGCR) Field Descriptions .....                             | 173        |
| 2-63. | Clock Control Register (CLKCNTRL) Field Descriptions .....                                  | 174        |
| 2-64. | ECP Control Register (EPCNTL) Field Descriptions .....                                      | 175        |
| 2-65. | DEV Parity Control Register 1 (DEVCR1) Field Descriptions.....                              | 176        |
| 2-66. | System Exception Control Register (SYSECR) Field Descriptions .....                         | 176        |
| 2-67. | System Exception Status Register (SYSESR) Field Descriptions.....                           | 177        |
| 2-68. | System Test Abort Status Register (SYSTASR) Field Descriptions .....                        | 178        |
| 2-69. | Global Status Register (GLBSTAT) Field Descriptions .....                                   | 179        |
| 2-70. | Device Identification Register (DEVID) Field Descriptions .....                             | 180        |
| 2-71. | Software Interrupt Vector Register (SSIVEC) Field Descriptions.....                         | 181        |
| 2-72. | System Software Interrupt Flag Register (SSIF) Field Descriptions .....                     | 182        |
| 2-73. | Secondary System Control Registers .....                                                    | 183        |
| 2-74. | PLL Control Register 3 (PLLCTL3) Field Descriptions .....                                   | 184        |
| 2-75. | CPU Logic BIST Clock Prescaler (STCLKDIV) Field Descriptions .....                          | 185        |
| 2-76. | Clock 2 Control Register (CLK2CNTRL) Field Descriptions .....                               | 185        |
| 2-77. | Peripheral Asynchronous Clock Configuration 1 Register (VCLKACON1) Field Descriptions ..... | 186        |

| 16-1. Arbitration According to Priority Queues and Priority Schemes .....                 | 558 |
| 16-2. Maximum Number of DMA Transactions per Channel in Non-Bypass Mode.....              | 565 |
| 16-3. Maximum Number of DMA Transactions per Channel in Bypass Mode.....                  | 565 |
| 16-4. Control Packet RAM .....                                                            | 568 |
| 16-5. Control Packet RAM .....                                                            | 568 |
| 16-6. Parity RAM.....                                                                     | 568 |
| 16-7. DMA Control Registers.....                                                          | 569 |
| 16-8. Control Packet Memory Map .....                                                     | 571 |
| 16-9. Global Control Register (GCTRL) Field Descriptions .....                            | 572 |
| 16-10. Channel Pending Register (PEND) Field Descriptions .....                           | 573 |
| 16-11. DMA Status Register (DMASTAT) Field Descriptions .....                             | 573 |
| 16-12. HW Channel Enable Set and Status Register (HWCHENAS) Field Descriptions.....       | 574 |
| 16-13. HW Channel Enable Reset and Status Register (HWCHENAR) Field Descriptions.....     | 574 |
| 16-14. SW Channel Enable Set and Status Register (SWCHENAS) Field Descriptions .....      | 575 |
| 16-15. SW Channel Enable Reset and Status Register (SWCHENAR) Field Descriptions .....    | 576 |
| 16-16. Channel Priority Set Register (CHPRIOS) Field Descriptions .....                   | 576 |
| 16-17. Channel Priority Reset Register (CHPRIOR) Field Descriptions .....                 | 577 |
| 16-18. Global Channel Interrupt Enable Set Register (GCHIENAS) Field Descriptions .....   | 577 |
| 16-19. Global Channel Interrupt Enable Reset Register (GCHIENAR) Field Descriptions ..... | 578 |
| 16-20. DMA Request Assignment Register 0 (DREQASI0) Field Descriptions .....              | 579 |
| 16-21. DMA Request Assignment Register 1 (DREQASI1) Field Descriptions .....              | 580 |
| 16-22. DMA Request Assignment Register 2 (DREQASI2) Field Descriptions .....              | 581 |
| 16-23. DMA Request Assignment Register 3 (DREQASI3) Field Descriptions .....              | 582 |
| 16-24. Port Assignment Register 0 (PAR0) Field Descriptions .....                         | 583 |
| 16-25. Port Assignment Register 1 (PAR1) Field Descriptions .....                         | 584 |
| 16-26. FTC Interrupt Mapping Register (FTCMAP) Field Descriptions .....                   | 585 |
| 16-27. LFS Interrupt Mapping Register (LFSMAP) Field Descriptions .....                   | 585 |
| 16-28. HBC Interrupt Mapping Register (HBCMAP) Field Descriptions .....                   | 586 |
| 16-29. BTC Interrupt Mapping Register (BTCMAP) Field Descriptions .....                   | 586 |
| 16-30. BER Interrupt Mapping Register (BERMAP) Field Descriptions.....                    | 587 |
| 16-31. FTC Interrupt Enable Set (FTCINTENAS) Field Descriptions .....                     | 587 |
| 16-32. FTC Interrupt Enable Reset (FTCINTENAR) Field Descriptions .....                   | 588 |
| 16-33. LFS Interrupt Enable Set (LFSINTENAS) Field Descriptions .....                     | 588 |
| 16-34. LFS Interrupt Enable Reset (LFSINTENAR) Field Descriptions .....                   | 589 |
| 16-35. HBC Interrupt Enable Set (HBCINTENAS) Field Descriptions.....                      | 589 |
| 16-36. HBC Interrupt Enable Reset (HBCINTENAR) Field Descriptions .....                   | 590 |
| 16-37. BTC Interrupt Enable Reset (BTCINTENAS) Field Descriptions .....                   | 590 |
| 16-38. BTC Interrupt Enable Reset (BTCINTENAR) Field Descriptions .....                   | 591 |
| 16-39. Global Interrupt Flag Register (GINTFLAG) Field Descriptions .....                 | 591 |
| 16-40. FTC INTERRUPT FLAG Register (FTCFLAG) Field Descriptions .....                     | 592 |
| 16-41. LFS Interrupt Flag Register (LFSFLAG) Field Descriptions .....                     | 592 |
| 16-42. HBC Interrupt Flag (HBCFLAG) Field Descriptions .....                              | 593 |
| 16-43. BTC Interrupt Flag Register (BTCFLAG) Field Descriptions .....                     | 593 |
| 16-44. BER Interrupt Flag Register (BERFLAG) Field Descriptions.....                      | 594 |
| 16-45. FTCA Interrupt Channel Offset Register (FTCAOFFSET) Field Descriptions .....       | 594 |

|                                                                                                  |     |
|--------------------------------------------------------------------------------------------------|-----|
| 16-46. LFSA Interrupt Channel Offset Register (LFSAOFFSET) Field Descriptions .....              | 595 |
| 16-47. HBCA Interrupt Channel Offset Register (HBCAOFFSET) Field Descriptions .....              | 595 |
| 16-48. BTCA Interrupt Channel Offset Register (BTCAOFFSET) Field Descriptions .....              | 596 |
| 16-49. BERA Interrupt Channel Offset Register (BERAOFFSET) Field Descriptions .....              | 596 |
| 16-50. FTCB Interrupt Channel Offset Register (FTCBOFFSET) Field Descriptions .....              | 597 |
| 16-51. LFSB Interrupt Channel Offset Register (LFSBOFFSET) Field Descriptions .....              | 597 |
| 16-52. HBCB Interrupt Channel Offset Register (HBCBOFFSET) Field Descriptions .....              | 598 |
| 16-53. BTCB Interrupt Channel Offset Register (BTCBOFFSET) Field Descriptions .....              | 598 |
| 16-54. BERB Interrupt Channel Offset Register (BERBOFFSET) Field Descriptions .....              | 599 |
| 16-55. Port Control Register (PTCRL) Field Descriptions .....                                    | 600 |
| 16-56. RAM Test Control (RTCTRL) Field Descriptions .....                                        | 601 |
| 16-57. Debug Control (DCTRL) Field Descriptions .....                                            | 602 |
| 16-58. Watch Point Register (WPR) Field Descriptions .....                                       | 603 |
| 16-59. Watch Mask Register (WMR) Field Descriptions .....                                        | 603 |
| 16-60. Port B Active Channel Source Address Register (PBACDADDR) Field Descriptions .....        | 604 |
| 16-61. Port B Active Channel Destination Address Register (PBACDADDR) Field Descriptions .....   | 604 |
| 16-62. Port B Active Channel Transfer Count Register (PBACTC) Field Descriptions .....           | 605 |
| 16-63. Parity Control Register (DAPCR) Field Descriptions .....                                  | 606 |
| 16-64. DMA Parity Error Address Register (DMPAR) Field Descriptions .....                        | 607 |
| 16-65. DMA Memory Protection Control Register (DMAMPCTRL) Field Descriptions .....               | 608 |
| 16-66. DMA Memory Protection Status Register (DMAMPST) Field Descriptions .....                  | 610 |
| 16-67. DMA Memory Protection Region 0 Start Address Register (DMAMPR0S) Field Descriptions ..... | 611 |
| 16-68. DMA Memory Protection Region 0 End Address Register (DMAMPR0E) Field Descriptions .....   | 611 |
| 16-69. DMA Memory Protection Region 1 Start Address Register (DMAMPR1S) Field Descriptions ..... | 612 |
| 16-70. DMA Memory Protection Region 1 End Address Register (DMAMPR1E) Field Descriptions .....   | 612 |
| 16-71. DMA Memory Protection Region 2 Start Address Register (DMAMPR2S) Field Descriptions ..... | 613 |
| 16-72. DMA Memory Protection Region 2 End Address Register (DMAMPR2E) Field Descriptions .....   | 613 |
| 16-73. DMA Memory Protection Region 3 Start Address Register (DMAMPR3S) Field Descriptions ..... | 614 |
| 16-74. DMA Memory Protection Region 3 End Address Register (DMAMPR3E) Field Descriptions .....   | 614 |
| 16-75. Initial Source Address (ISADDR) Field Descriptions .....                                  | 615 |
| 16-76. Initial Destination Address Register (IDADDR) Field Descriptions .....                    | 616 |
| 16-77. Initial Transfer Count Register (ITCOUNT) Field Descriptions .....                        | 616 |
| 16-78. Channel Control Register (CHCTRL) Field Descriptions .....                                | 617 |
| 16-79. Element Index Offset Register (EIOFF) Field Descriptions .....                            | 618 |
| 16-80. Frame Index Offset Register (FIOFF) Field Descriptions .....                              | 618 |
| 16-81. Current Source Address Register (CSADDR) Field Descriptions .....                         | 619 |
| 16-82. Current Destination Address Register (CDADDR) Field Descriptions .....                    | 619 |
| 16-83. Current Transfer Count Register (CTCOUNT) Field Descriptions .....                        | 620 |
| 17-1. EMIF Pins Used to Access Both SDRAM and Asynchronous Memories .....                        | 624 |
| 17-2. EMIF Pins Specific to SDRAM .....                                                          | 625 |
| 17-3. EMIF Pins Specific to Asynchronous Memory .....                                            | 625 |
| 17-4. EMIF SDRAM Commands .....                                                                  | 626 |
| 17-5. Truth Table for SDRAM Commands .....                                                       | 626 |
| 17-6. 16-bit EMIF Address Pin Connections .....                                                  | 628 |
| 17-7. Description of the SDRAM Configuration Register (SDCR) .....                               | 629 |
| 17-8. Description of the SDRAM Refresh Control Register (SDRCR) .....                            | 629 |
| 17-9. Description of the SDRAM Timing Register (SDTIMR) .....                                    | 630 |
| 17-10. Description of the SDRAM Self Refresh Exit Timing Register (SDSRETR) .....                | 630 |
| 17-11. SDRAM LOAD MODE REGISTER Command .....                                                    | 631 |

|                                                                                            |     |
|--------------------------------------------------------------------------------------------|-----|
| 17-12. Refresh Urgency Levels.....                                                         | 632 |
| 17-13. Mapping from Logical Address to EMIF Pins for 16-bit SDRAM .....                    | 637 |
| 17-14. Normal Mode vs. Select Strobe Mode .....                                            | 638 |
| 17-15. Description of the Asynchronous <i>m</i> Configuration Register (CEnCFG) .....      | 640 |
| 17-16. Description of the Asynchronous Wait Cycle Configuration Register (AWCC) .....      | 641 |
| 17-17. Description of the EMIF Interrupt Mask Set Register (INTMSKSET) .....               | 642 |
| 17-18. Description of the EMIF Interrupt Mast Clear Register (INTMSKCLR) .....             | 642 |
| 17-19. Asynchronous Read Operation in Normal Mode .....                                    | 642 |
| 17-20. Asynchronous Write Operation in Normal Mode.....                                    | 644 |
| 17-21. Asynchronous Read Operation in Select Strobe Mode .....                             | 646 |
| 17-22. Asynchronous Write Operation in Select Strobe Mode .....                            | 648 |
| 17-23. Interrupt Monitor and Control Bit Fields .....                                      | 652 |
| 17-24. External Memory Interface (EMIF) Registers .....                                    | 656 |
| 17-25. Module ID Register (MIDR) Field Descriptions .....                                  | 656 |
| 17-26. Asynchronous Wait Cycle Configuration Register (AWCCR) Field Descriptions.....      | 657 |
| 17-27. SDRAM Configuration Register (SDCR) Field Descriptions .....                        | 658 |
| 17-28. SDRAM Refresh Control Register (SDRCR) Field Descriptions.....                      | 659 |
| 17-29. Asynchronous <i>n</i> Configuration Register (CEnCFG) Field Descriptions .....      | 660 |
| 17-30. SDRAM Timing Register (SDTIMR) Field Descriptions.....                              | 661 |
| 17-31. SDRAM Self Refresh Exit Timing Register (SDSRETR) Field Descriptions .....          | 662 |
| 17-32. EMIF Interrupt Raw Register (INTRAW) Field Descriptions.....                        | 663 |
| 17-33. EMIF Interrupt Mask Register (INTMSK) Field Descriptions .....                      | 664 |
| 17-34. EMIF Interrupt Mask Set Register (INTMSKSET) Field Descriptions .....               | 665 |
| 17-35. EMIF Interrupt Mask Clear Register (INTMSKCLR) Field Descriptions .....             | 666 |
| 17-36. Page Mode Control Register (PMCR) Field Descriptions .....                          | 667 |
| 17-37. SR Field Value For the EMIF to K4S641632H-TC(L)70 Interface.....                    | 668 |
| 17-38. SDTIMR Field Calculations for the EMIF to K4S641632H-TC(L)70 Interface .....        | 670 |
| 17-39. RR Calculation for the EMIF to K4S641632H-TC(L)70 Interface.....                    | 671 |
| 17-40. RR Calculation for the EMIF to K4S641632H-TC(L)70 Interface.....                    | 671 |
| 17-41. SDCR Field Values For the EMIF to K4S641632H-TC(L)70 Interface .....                | 672 |
| 17-42. AC Characteristics for a Read Access .....                                          | 673 |
| 17-43. AC Characteristics for a Write Access .....                                         | 673 |
| 18-1. POM Registers .....                                                                  | 679 |
| 18-2. POM Global Control Register (POMGLBCTRL) Field Descriptions.....                     | 680 |
| 18-3. POM Revision ID (POMREV) Field Descriptions .....                                    | 681 |

| 23-29. Request Enable Set Register (HETREQENS) Field Descriptions .....             | 1082 |
| 23-30. Request Enable Clear Register (HETREQENC) Field Descriptions.....            | 1082 |
| 23-31. Request Destination Select Register (HETREQDS) Field Descriptions.....       | 1083 |
| 23-32. N2HET Direction Register (HETDIR) Field Descriptions .....                   | 1084 |
| 23-33. N2HET Data Input Register (HETDIN) Field Descriptions .....                  | 1085 |
| 23-34. N2HET Data Output Register (HETDOUT) Field Descriptions .....                | 1085 |
| 23-35. N2HET Data Set Register (HETDSET) Field Descriptions .....                   | 1086 |
| 23-36. N2HET Data Clear Register (HETDCLR) Field Descriptions .....                 | 1086 |
| 23-37. N2HET Open Drain Register (HETPDR) Field Descriptions.....                   | 1087 |
| 23-38. N2HET Pull Disable Register (HETPULDIS) Field Descriptions .....             | 1087 |
| 23-39. N2HET Pull Select Register (HETPSL) Field Descriptions .....                 | 1088 |
| 23-40. Parity Control Register (HETPCR) Field Descriptions.....                     | 1089 |
| 23-41. Parity Address Register (HETPAR) Field Descriptions.....                     | 1090 |
| 23-42. Parity Pin Register (HETPPR) Field Descriptions.....                         | 1091 |
| 23-43. Known State on Parity Error .....                                            | 1091 |
| 23-44. Suppression Filter Preload Register (HETSFPRLD) Field Descriptions .....     | 1092 |
| 23-45. Suppression Filter Enable Register (HETSFENA) Field Descriptions.....        | 1092 |
| 23-46. Loop Back Pair Select Register (HETLBPSEL) Field Descriptions.....           | 1093 |
| 23-47. Loop Back Pair Direction Register (HETLBPDIR) Field Descriptions .....       | 1094 |

|                                                                                           |      |
|-------------------------------------------------------------------------------------------|------|
| 23-48. NHET Pin Disable Register (HETPINDIS) Field Descriptions .....                     | 1095 |
| 23-49. Instruction Summary .....                                                          | 1096 |
| 23-50. FLAGS Generated by Instruction .....                                               | 1097 |
| 23-51. Interrupt Capable Instructions .....                                               | 1097 |
| 23-52. Arithmetic / Bitwise Logic Sub-Opcodes .....                                       | 1109 |
| 23-53. Source Operand Choices .....                                                       | 1109 |
| 23-54. Destination Operand Choices .....                                                  | 1109 |
| 23-55. Shift Encoding.....                                                                | 1110 |
| 23-56. Execution Time for ADC, ADD, AND, OR, SBB, SUB, XOR Instructions .....             | 1110 |
| 23-57. Move Types for ADM32 .....                                                         | 1115 |
| 23-58. Edge Select Encoding for APCNT .....                                               | 1118 |
| 23-59. Branch Condition Encoding for BR .....                                             | 1121 |
| 23-60. DADM64 Control Field Description .....                                             | 1126 |
| 23-61. Event Encoding Format for ECNT .....                                               | 1133 |
| 23-62. Magnitude Compare Order for MCMP .....                                             | 1135 |
| 23-63. Move Type Encoding Selection .....                                                 | 1138 |
| 23-64. MOV64 Control Field Descriptions .....                                             | 1142 |
| 23-65. Comparison Type Encoding Format .....                                              | 1142 |
| 23-66. Counter Type Encoding Format .....                                                 | 1144 |
| 23-67. Comparison Type Encoding Format .....                                              | 1150 |
| 23-68. RADM64 Control Field Descriptions .....                                            | 1150 |
| 23-69. Step Width Encoding for SCNT .....                                                 | 1156 |
| 23-70. SHIFT MODE Encoding Format .....                                                   | 1159 |
| 23-71. SHIFT Condition Encoding .....                                                     | 1159 |
| 23-72. Event Encoding Format for WCAP .....                                               | 1162 |
| 23-73. Event Encoding Format for WCAPE .....                                              | 1164 |
| 24-1. CPENA / TMBx Priority Rules .....                                                   | 1173 |
| 24-2. Triggered Control Packets.....                                                      | 1176 |
| 24-3. DCP RAM .....                                                                       | 1179 |
| 24-4. DCP Parity RAM.....                                                                 | 1179 |
| 24-5. Field Addresses of the WCAP, ECNT, PCNT Example .....                               | 1180 |
| 24-6. 32-Bit-Transfer of Data Fields .....                                                | 1181 |
| 24-7. Destination Buffer Values .....                                                     | 1181 |
| 24-8. 64-Bit-Transfer of Control Field and Data Fields .....                              | 1181 |
| 24-9. Destination Buffer Values .....                                                     | 1182 |
| 24-10. Control Register Mapping .....                                                     | 1183 |
| 24-11. Global Control Register (HTU GC) Field Descriptions .....                          | 1184 |
| 24-12. Control Packet Enable Register (HTU CPENA) Field Descriptions.....                 | 1185 |
| 24-13. CPENA Write Results.....                                                           | 1185 |
| 24-14. CPENA Read Results.....                                                            | 1185 |
| 24-15. Control Packet (CP) Busy Register 0 (HTU BUSY0) Field Descriptions .....           | 1186 |
| 24-16. Control Packet (CP) Busy Register 1 (HTU BUSY1) Field Descriptions .....           | 1187 |
| 24-17. Control Packet (CP) Busy Register 2 (HTU BUSY2) Field Descriptions.....            | 1187 |
| 24-18. Control Packet (CP) Busy Register 3 (HTU BUSY3) Field Descriptions .....           | 1188 |
| 24-19. Active Control Packet and Error Register (HTU ACPE) Field Descriptions .....       | 1188 |
| 24-20. Request Lost and Bus Error Control Register (HTU RLBECTRL) Field Descriptions..... | 1190 |
| 24-21. Buffer Full Interrupt Enable Set Register (HTU BFINTS) Field Descriptions .....    | 1191 |
| 24-22. Buffer Full Interrupt Enable Clear Register (HTU BFINTC) Field Descriptions .....  | 1191 |
| 24-23. Interrupt Mapping Register (HTU INTMAP) Field Descriptions .....                   | 1192 |

|                                                                                              |      |
|----------------------------------------------------------------------------------------------|------|
| 24-24. Interrupt Offset Register 0 (HTU INTOFF0) Field Descriptions .....                    | 1193 |
| 24-25. Interrupt Offset Register 1 (HTU INTOFF1) Field Descriptions .....                    | 1194 |
| 24-26. Buffer Initialization Mode Register (HTU BIM) Field Descriptions .....                | 1195 |
| 24-27. Buffer Initialization .....                                                           | 1195 |
| 24-28. Request Lost Flag Register (HTU RLOSTFL) Field Descriptions .....                     | 1197 |
| 24-29. Buffer Full Interrupt Flag Register (HTU BFINTFL) Field Descriptions .....            | 1197 |
| 24-30. BER Interrupt Flag Register (HTU BERINTFL) Field Descriptions .....                   | 1198 |
| 24-31. Memory Protection 1 Start Address Register (HTU MP1S) Field Descriptions .....        | 1199 |
| 24-32. Memory Protection 1 End Address Register (HTU MP1E) Field Descriptions .....          | 1199 |
| 24-33. Debug Control Register (HTU DCTRL) Field Descriptions .....                           | 1200 |
| 24-34. Watch Point Register (HTU WPR) Field Descriptions .....                               | 1201 |
| 24-35. Watch Mask Register (HTU WMR) Field Descriptions .....                                | 1201 |
| 24-36. Module Identification Register (HTU ID) Field Descriptions .....                      | 1202 |
| 24-37. Parity Control Register (HTU PCR) Field Descriptions .....                            | 1203 |
| 24-38. Parity Address Register (HTU PAR) Field Descriptions .....                            | 1204 |
| 24-39. Memory Protection Control and Status Register (HTU MPCS) Field Descriptions .....     | 1205 |
| 24-40. Memory Protection 0 Start address Register (HTU MP0S) Field Descriptions .....        | 1207 |
| 24-41. Memory Protection End Address Register (HTU MP0E) Field Descriptions .....            | 1207 |
| 24-42. Double Control Packet Memory Map .....                                                | 1208 |
| 24-43. Initial Full Address A Register (HTU IFADDRA) Field Descriptions .....                | 1209 |
| 24-44. Initial Full Address B Register (HTU IFADDRB) Field Descriptions .....                | 1209 |
| 24-45. Initial NHET Address and Control Register (HTU IHADDRCT) Field Descriptions .....     | 1210 |
| 24-46. Initial Transfer Count Register (HTU ITCOUNT) Field Descriptions .....                | 1211 |
| 24-47. Current Full Address A Register (HTU CFADDRA) Field Descriptions .....                | 1212 |
| 24-48. Current Full Address B Register (HTU CFADDRB) Field Descriptions .....                | 1213 |
| 24-49. Initial Transfer Count Register (HTU CFCOUNT) Field Descriptions .....                | 1214 |
| 24-50. Application Examples for Setting the Transfer Modes of CP A and B of a DCP .....      | 1215 |
| 25-1. GPIO Control Registers Summary .....                                                   | 1224 |
| 25-2. GPIO Global Control Register (GIOGCR0) Field Descriptions .....                        | 1225 |
| 25-3. GPIO Interrupt Detect Register (GIOINTDET) Field Descriptions .....                    | 1226 |
| 25-4. GPIO Interrupt Polarity Register (GIOPOL) Field Descriptions .....                     | 1227 |
| 25-5. GPIO Interrupt Enable Set Register (GIOENASET) Field Descriptions .....                | 1228 |
| 25-6. GPIO Interrupt Enable Clear Register (GIOENACLR) Field Descriptions .....              | 1229 |
| 25-7. GPIO Interrupt Priority Register (GIOLVLSET) Field Descriptions .....                  | 1230 |
| 25-8. GPIO Interrupt Priority Register (GIOLVLCLR) Field Descriptions .....                  | 1232 |
| 25-9. GPIO Interrupt Flag Register (GIOFLG) Field Descriptions .....                         | 1233 |
| 25-10. GPIO Offset 1 Register (GIOOFF1) Field Descriptions .....                             | 1234 |
| 25-11. GPIO Offset 2 Register (GIOOFF2) Field Descriptions .....                             | 1235 |
| 25-12. GPIO Emulation 1 Register (GIOEMU1) Field Descriptions .....                          | 1236 |
| 25-13. GPIO Emulation 2 Register (GIOEMU2) Field Descriptions .....                          | 1237 |
| 25-14. GPIO Data Direction Registers [A-H][7:0] (GIODIR[A-H][7:0]) Field Descriptions .....  | 1238 |
| 25-15. GPIO Data Input Registers [A-H][7:0] (GIODIN[A-H][7:0]) Field Descriptions .....      | 1238 |
| 25-16. GPIO Data Output Registers [A-H][7:0] (GIODOUT[A-H][7:0]) Field Descriptions .....    | 1239 |
| 25-17. GPIO Data Set Registers [A-H][7:0] (GIODSET[A-H][7:0]) Field Descriptions .....       | 1239 |
| 25-18. GPIO Data Clear Registers [A-H][7:0] (GIODCLR[A-H][7:0]) Field Descriptions .....     | 1240 |
| 25-19. GPIO Open Drain Registers [A-H][7:0] (GIOPDR[A-H][7:0]) Field Descriptions .....      | 1240 |
| 25-20. GPIO Pull Disable Registers [A-H][7:0] (GIOPULDIS[A-H][7:0]) Field Descriptions ..... | 1241 |
| 25-21. GPIO Pull Select Registers [A-H][7:0] (GIOPSL[A-H][7:0]) Field Descriptions .....     | 1241 |
| 25-22. Output Buffer, and Pull Control Behavior for GPIO Pins .....                          | 1242 |

|                                                                                             |      |
|---------------------------------------------------------------------------------------------|------|
| 26-1. FlexRay Address Range Table .....                                                     | 1248 |
| 26-2. FlexRay Transfer Unit Event Trigger Conditions .....                                  | 1253 |
| 26-3. Mirroring Address Mapping .....                                                       | 1255 |
| 26-4. Mirroring Address Mapping .....                                                       | 1256 |
| 26-5. Error Modes of the POC (Degradation Model) .....                                      | 1262 |
| 26-6. State Transitions of Communication Controller Overall State Machine .....             | 1264 |
| 26-7. State Transitions WAKEUP .....                                                        | 1268 |
| 26-8. Definition of Cycle Set .....                                                         | 1277 |
| 26-9. Examples for Valid Cycle Sets .....                                                   | 1277 |
| 26-10. Channel Filtering Configuration .....                                                | 1278 |
| 26-11. Scan of Message RAM .....                                                            | 1284 |
| 26-12. Assignment of Input Buffer Command Mask Bits .....                                   | 1287 |
| 26-13. Assignment of Input Buffer Command Request bits .....                                | 1287 |
| 26-14. Assignment of Output Buffer Command Mask Bits .....                                  | 1289 |
| 26-15. Assignment of Output Buffer Command Request Bits .....                               | 1289 |
| 26-16. Module Interrupt Flags and Interrupt Line Enable .....                               | 1302 |
| 26-17. Transfer Unit Register Summary .....                                                 | 1303 |
| 26-18. Global Static Number 0 (GSN0) Field Descriptions .....                               | 1305 |
| 26-19. Global Static Number 1 (GSN1) Field Descriptions .....                               | 1305 |
| 26-20. Global Control Set/Reset (GCS/R) Field Descriptions.....                             | 1307 |
| 26-21. Transfer Status Current Buffer (TSCB) Field Descriptions.....                        | 1309 |
| 26-22. Last Transferred Buffer to Communication Controller (LTBCC) Field Descriptions ..... | 1310 |
| 26-23. Last Transferred Buffer to System Memory (LTBSM) Field Descriptions .....            | 1310 |
| 26-24. Transfer Base Address (TBA) Field Descriptions .....                                 | 1311 |
| 26-25. Next Transfer Base Address (NTBA) Field Descriptions .....                           | 1311 |
| 26-26. Base Address of Mirrored Status (BAMS) Field Descriptions .....                      | 1312 |
| 26-27. Start Address of Memory Protection (SAMP) Field Descriptions .....                   | 1312 |
| 26-28. End Address of Memory Protection (EAMP) Field Descriptions .....                     | 1313 |
| 26-29. Transfer to System Memory Occurred 1 (TSMO1) Field Descriptions .....                | 1314 |
| 26-30. Transfer to System Memory Occurred 2 (TSMO2) Field Descriptions .....                | 1314 |
| 26-31. Transfer to System Memory Occurred 3 (TSMO3) Field Descriptions .....                | 1315 |
| 26-32. Transfer to System Memory Occurred 4 (TSMO4) Field Descriptions .....                | 1315 |
| 26-33. (Transfer to Communication Controller Occurred 1 (TCCO1) Field Descriptions .....    | 1316 |
| 26-34. (Transfer to Communication Controller Occurred 2 (TCCO2) Field Descriptions .....    | 1316 |
| 26-35. (Transfer to Communication Controller Occurred 3 (TCCO3) Field Descriptions .....    | 1317 |
| 26-36. (Transfer to Communication Controller Occurred 4 (TCCO4) Field Descriptions .....    | 1317 |
| 26-37. (Transfer Occurred Offset (TOOFF) Field Descriptions .....                           | 1318 |
| 26-38. Parity Error Address (PEADR) Field Descriptions .....                                | 1319 |
| 26-39. Coding of Parity Error Address .....                                                 | 1319 |
| 26-40. Transfer Error Interrupt Flag (TEIF) Field Descriptions .....                        | 1320 |
| 26-41. Transfer Error Interrupt Enable Set (TEIRES) .....                                   | 1321 |
| 26-42. Transfer Error Interrupt Enable Reset (TEIRER) .....                                 | 1322 |
| 26-43. Trigger Transfer to System Memory Set 1 (TTSMS1) Field Descriptions .....            | 1323 |
| 26-44. Trigger Transfer to System Memory Reset 1 (TTSMR1) Field Descriptions .....          | 1323 |
| 26-45. Trigger Transfer to System Memory Set 2 (TTSMS2) Field Descriptions .....            | 1324 |
| 26-46. Trigger Transfer to System Memory Reset 2 (TTSMR2) Field Descriptions .....          | 1324 |
| 26-47. Trigger Transfer to System Memory Set 3 (TTSMS3) Field Descriptions .....            | 1324 |
| 26-48. Trigger Transfer to System Memory Reset 3 (TTSMR3) Field Descriptions .....          | 1325 |
| 26-49. Trigger Transfer to System Memory Set 4 (TTSMS4) Field Descriptions .....            | 1325 |

|                                                                                                         |      |
|---------------------------------------------------------------------------------------------------------|------|
| 26-50. Trigger Transfer to System Memory Reset 4 (TTSMR4) Field Descriptions .....                      | 1325 |
| 26-51. Trigger Transfer to Communication Controller Set 1 (TTCCS1) Field Descriptions .....             | 1326 |
| 26-52. Trigger Transfer to Communication Controller Reset 1 (TTCCR1) Field Descriptions .....           | 1326 |
| 26-53. Trigger Transfer to Communication Controller Set 2 (TTCCS2) Field Descriptions .....             | 1327 |
| 26-54. Trigger Transfer to Communication Controller Reset 2 (TTCCR2) Field Descriptions .....           | 1327 |
| 26-55. Trigger Transfer to Communication Controller Set 3 (TTCCS3) Field Descriptions .....             | 1327 |
| 26-56. Trigger Transfer to Communication Controller Reset 3 (TTCCR3) Field Descriptions .....           | 1328 |
| 26-57. Trigger Transfer to Communication Controller Set 4 (TTCCS4) Field Descriptions .....             | 1328 |
| 26-58. Trigger Transfer to Communication Controller Reset 4 (TTCCR4) Field Descriptions .....           | 1328 |
| 26-59. Enable Transfer on Event to System Memory Set 1 Field Descriptions .....                         | 1329 |
| 26-60. Enable Transfer on Event to System Memory Reset 1 (ETESMR1) Field Descriptions .....             | 1329 |
| 26-61. Enable Transfer on Event to System Memory Set 2 Field Descriptions .....                         | 1330 |
| 26-62. Enable Transfer on Event to System Memory Reset 2 (ETESMR2) Field Descriptions .....             | 1330 |
| 26-63. Enable Transfer on Event to System Memory Set 3 Field Descriptions .....                         | 1330 |
| 26-64. Enable Transfer on Event to System Memory Reset 3 (ETESMR3) Field Descriptions .....             | 1331 |
| 26-65. Enable Transfer on Event to System Memory Set 4 Field Descriptions .....                         | 1331 |
| 26-66. Enable Transfer on Event to System Memory Reset 4 (ETESMR4) Field Descriptions .....             | 1331 |
| 26-67. Clear on Event to System Memory Set 1 (CESMS1) Field Descriptions .....                          | 1332 |
| 26-68. Clear on Event to System Memory Reset 1 (CESMR1) Field Descriptions .....                        | 1332 |
| 26-69. Clear on Event to System Memory Set 2 (CESMS2) Field Descriptions .....                          | 1333 |
| 26-70. Clear on Event to System Memory Reset 2 (CESMR2) Field Descriptions .....                        | 1333 |
| 26-71. Clear on Event to System Memory Set 3 (CESMS3) Field Descriptions .....                          | 1333 |
| 26-72. Clear on Event to System Memory Reset 3 (CESMR3) Field Descriptions .....                        | 1334 |
| 26-73. Clear on Event to System Memory Set 4 (CESMS4) Field Descriptions .....                          | 1334 |
| 26-74. Clear on Event to System Memory Reset 4 (CESMR4) Field Descriptions .....                        | 1334 |
| 26-75. Transfer to System Memory Interrupt Enable Set 1 (TSMIES1) Field Descriptions .....              | 1335 |
| 26-76. Transfer to System Memory Interrupt Enable Reset 1 (TSMIER1) Field Descriptions .....            | 1335 |
| 26-77. Transfer to System Memory Interrupt Enable Set 2 (TSMIES2) Field Descriptions .....              | 1336 |
| 26-78. Transfer to System Memory Interrupt Enable Reset 2 (TSMIER2) Field Descriptions .....            | 1336 |
| 26-79. Transfer to System Memory Interrupt Enable Set 3 (TSMIES3) Field Descriptions .....              | 1336 |
| 26-80. Transfer to System Memory Interrupt Enable Reset 3 (TSMIER3) Field Descriptions .....            | 1337 |
| 26-81. Transfer to System Memory Interrupt Enable Set 4 (TSMIES4) Field Descriptions .....              | 1337 |
| 26-82. Transfer to System Memory Interrupt Enable Reset 4 (TSMIER4) Field Descriptions .....            | 1337 |
| 26-83. Transfer to Communication Controller Interrupt Enable Set 1 (TCCIES1) Field Descriptions .....   | 1338 |
| 26-84. Transfer to Communication Controller Interrupt Enable Reset 1 (TCCIER1) Field Descriptions ..... | 1338 |
| 26-85. Transfer to Communication Controller Interrupt Enable Set 2 (TCCIES2) Field Descriptions .....   | 1339 |
| 26-86. Transfer to Communication Controller Interrupt Enable Reset 2 (TCCIER2) Field Descriptions ..... | 1339 |
| 26-87. Transfer to Communication Controller Interrupt Enable Set 3 (TCCIES3) Field Descriptions .....   | 1340 |
| 26-88. Transfer to Communication Controller Interrupt Enable Reset 3 (TCCIER3) Field Descriptions ..... | 1340 |
| 26-89. Transfer to Communication Controller Interrupt Enable Set 4 (TCCIES4) Field Descriptions .....   | 1341 |
| 26-90. Transfer to Communication Controller Interrupt Enable Reset 4 (TCCIER4) Field Descriptions ..... | 1341 |
| 26-91. Transfer Configuration RAM (TCR) Field Descriptions .....                                        | 1342 |
| 26-92. Parity Information in TCR Parity Test Mode Field Descriptions .....                              | 1343 |
| 26-93. Communication Controller Register Map .....                                                      | 1345 |
| 26-94. Test Register 1 (TEST1) Field Descriptions .....                                                 | 1348 |
| 26-95. Test Register 2 (TEST2) Field Descriptions .....                                                 | 1352 |
| 26-96. Lock Register (LCK) Field Descriptions .....                                                     | 1354 |
| 26-97. Error Interrupt Register (EIR) Field Descriptions .....                                          | 1355 |
| 26-98. Status Interrupt Register (SIR) Field Descriptions .....                                         | 1357 |

|                                                                                          |      |

| 26-163. Read Header Section Register 3 (RDHS3) Field Descriptions .....              | 1423 |
| 26-164. Message Buffer Status Register (MBS) Field Descriptions.....                 | 1424 |
| 26-165. Output Buffer Command Mask Register (MBS) Field Descriptions .....           | 1427 |
| 26-166. Output Buffer Command Mask Register (OBCR) Field Descriptions .....          | 1428 |
| 26-167. Assignment of FlexRay Configuration Parameters .....                         | 1431 |
| 27-1. Parameters of the CAN Bit Time .....                                           | 1437 |
| 27-2. Message Object Field Descriptions .....                                        | 1444 |
| 27-3. Message RAM Addressing in Debug/Suspend and RDA mode .....                     | 1446 |
| 27-4. Message Interface Register Sets 1 and 2 .....                                  | 1448 |
| 27-5. Message Interface Register 3 .....                                             | 1450 |
| 27-6. DCAN Control Registers.....                                                    | 1469 |
| 27-7. CAN Control Register Field Descriptions.....                                   | 1471 |
| 27-8. Error and Status Register Field Descriptions .....                             | 1473 |
| 27-9. Error Counter Register Field Descriptions .....                                | 1475 |
| 27-10. Bit Timing Register Field Descriptions.....                                   | 1476 |
| 27-11. Interrupt Register Field Descriptions .....                                   | 1477 |
| 27-12. Test Register Field Descriptions.....                                         | 1478 |
| 27-13. Parity Error Code Register Field Descriptions.....                            | 1479 |
| 27-14. Auto-Bus-On Time Register Field Descriptions .....                            | 1480 |
| 27-15. Transmission Request Registers Field Descriptions.....                        | 1481 |
| 27-16. New Data Registers Field Descriptions.....                                    | 1483 |
| 27-17. Interrupt Pending Registers Field Descriptions.....                           | 1485 |
| 27-18. Message Valid Registers Field Descriptions.....                               | 1487 |
| 27-19. Interrupt Multiplexer Registers Field Descriptions.....                       | 1488 |
| 27-20. IF1/IF2 Command Register Field Descriptions .....                             | 1490 |
| 27-21. IF1/IF2 Mask Register Field Descriptions .....                                | 1492 |
| 27-22. IF1/IF2 Arbitration Register Field Descriptions .....                         | 1493 |
| 27-23. IF1/IF2 Message Control Register Field Descriptions .....                     | 1495 |
| 27-24. IF3 Observation Register Field Descriptions.....                              | 1497 |
| 27-25. IF3 Mask Register Field Descriptions.....                                     | 1499 |
| 27-26. IF3 Arbitration Register Field Descriptions .....                             | 1500 |
| 27-27. IF3 Message Control Register Field Descriptions.....                          | 1501 |
| 27-28. IF3 Update Control Register Field Descriptions.....                           | 1503 |
| 27-29. CAN TX IO Control Register Field Descriptions.....                            | 1504 |

|                                                                                                        |      |
|--------------------------------------------------------------------------------------------------------|------|
| 27-30. CAN RX IO Control Register Field Descriptions .....                                             | 1505 |
| 28-1. Pin Configurations .....                                                                         | 1510 |
| 28-2. Clocking Modes .....                                                                             | 1517 |
| 28-3. Pin Mapping for SIMO Pin with MSB First .....                                                    | 1525 |
| 28-4. Pin Mapping for SOMI Pin with MSB First .....                                                    | 1525 |
| 28-5. Pin Mapping for SIMO Pin with LSB First .....                                                    | 1526 |
| 28-6. Pin Mapping for SOMI Pin with LSB First .....                                                    | 1526 |
| 28-7. SPI Registers .....                                                                              | 1539 |
| 28-8. SPI Global Control Register 0 (SPIGCR0) Field Descriptions.....                                  | 1540 |
| 28-9. SPI Global Control Register 1 (SPIGCR1) Field Descriptions.....                                  | 1541 |
| 28-10. SPI Interrupt Register (SPIINT0) Field Descriptions.....                                        | 1542 |
| 28-11. SPI Interrupt Level Register (SPIILVL) Field Descriptions.....                                  | 1544 |
| 28-12. SPI Flag Register (SPIFLG) Field Descriptions .....                                             | 1545 |
| 28-13. SPI Pin Control (SPIPC0) Field Descriptions.....                                                | 1548 |
| 28-14. SPI Pin Control Register (SPIPC1) Field Descriptions .....                                      | 1549 |
| 28-15. SPI Pin Control Register 2 (SPIPC2) Field Descriptions.....                                     | 1551 |
| 28-16. SPI Pin Control Register 3 (SPIPC3) Field Descriptions.....                                     | 1552 |
| 28-17. SPI Pin Control Register 4 (SPIPC4) Field Descriptions.....                                     | 1553 |
| 28-18. SPI Pin Control Register 5 (SPIPC5) Field Descriptions.....                                     | 1555 |
| 28-19. SPI Pin Control Register 6 (SPIPC6) Field Descriptions.....                                     | 1557 |
| 28-20. SPI Pin Control Register 7 (SPIPC7) Field Descriptions.....                                     | 1558 |
| 28-21. SPI Pin Control Register 8 (SPIPC8) Field Descriptions.....                                     | 1559 |
| 28-22. SPI Transmit Data Register 0 (SPIDAT0) Field Descriptions .....                                 | 1560 |
| 28-23. SPI Transmit Data Register 1 (SPIDAT1) Field Descriptions .....                                 | 1561 |
| 28-24. SPI Receive Buffer Register (SPIBUF) Field Descriptions.....                                    | 1562 |
| 28-25. SPI Emulation Register (SPIEMU) Field Descriptions.....                                         | 1564 |
| 28-26. SPI Delay Register (SPIDELAY) Field Descriptions .....                                          | 1564 |
| 28-27. SPI Default Chip Select Register (SPIDEF) Field Descriptions .....                              | 1567 |
| 28-28. SPI Data Format Registers (SPIFMT) Field Descriptions.....                                      | 1568 |
| 28-29. Transfer Group Interrupt Vector 0 (INTVECT0) .....                                              | 1570 |
| 28-30. Transfer Group Interrupt Vector 1 (INTVECT1) .....                                              | 1571 |
| 28-31. SPI Parallel/Modulo Mode Control Register (SPIPMCTRL) Field Descriptions .....                  | 1573 |
| 28-32. Multi-buffer Mode Enable Register (MIBSPIE) Field Descriptions .....                            | 1575 |
| 28-33. TG Interrupt Enable Set Register (TGITENST) Field Descriptions .....                            | 1576 |
| 28-34. TG Interrupt Enable Clear Register (TGITENCR) Field Descriptions .....                          | 1577 |
| 28-35. Transfer Group Interrupt Level Set Register (TGITLVST) Field Descriptions .....                 | 1578 |
| 28-36. Transfer Group Interrupt Level Clear Register (TGITLVCR) Field Descriptions .....               | 1579 |
| 28-37. Transfer Group Interrupt Flag Register (TGINTFLG) Field Descriptions.....                       | 1580 |
| 28-38. Tick Count Register (TICKCNT) Field Descriptions.....                                           | 1581 |
| 28-39. Last TG End Pointer (LTGPEND) Field Descriptions.....                                           | 1582 |
| 28-40. TG Control Registers (TGxCTRL) Field Descriptions .....                                         | 1583 |
| 28-41. DMA Channel Control Register (DMAxCTRL) Field Descriptions .....                                | 1586 |
| 28-42. MibSPI DMAxCOUNT Register (ICOUNT) Field Descriptions .....                                     | 1588 |
| 28-43. MibSPI DMA Large Count Register (DMACNTLEN) Field Descriptions .....                            | 1589 |
| 28-44. Multi-buffer RAM Uncorrectable Parity Error Control Register (UERRCTRL) Field Descriptions..... | 1589 |
| 28-45. Multi-buffer RAM Uncorrectable Parity Error Status Register (UERRSTAT) Field Descriptions.....  | 1590 |
| 28-46. RXRAM Uncorrectable Parity Error Address Register (UERRADDR1) Field Descriptions.....           | 1591 |
| 28-47. TXRAM Uncorrectable Parity Error Address Register (UERRADDR0) Field Descriptions .....          | 1592 |
| 28-48. RXRAM Overrun Buffer Address Register (RXOVRN_BUF_ADDR) Field Descriptions.....                 | 1593 |

|                                                                                                   |      |
|---------------------------------------------------------------------------------------------------|------|
| 28-49. I/O-Loopback Test Control Register (IOLPBKTSTCR) Field Descriptions .....                  | 1594 |
| 28-50. SPI Extended Prescale Register 1 (EXTENDED_PRESCALE1) Field Descriptions .....             | 1596 |
| 28-51. SPI Extended Prescale Register 2 (EXTENDED_PRESCALE2) Field Descriptions .....             | 1598 |
| 28-52. Multi-buffer RAM Register Summary .....                                                    | 1601 |
| 28-53. Multi-buffer RAM Transmit Data Register Field Descriptions.....                            | 1602 |
| 28-54. Multi-buffer Receive Buffer Register Field Descriptions.....                               | 1604 |
| 28-55. Timing Parameters of SPI/MibSPI Pins in Master Mode .....                                  | 1612 |
| 28-56. Timing Parameters of SPI/MibSPI Pins in Slave Mode. ....                                   | 1614 |
| 29-1. Superfractional Bit Modulation for SCI Mode (Normal Configuration) .....                    | 1623 |
| 29-2. Superfractional Bit Modulation for SCI Mode (Maximum Configuration) .....                   | 1624 |
| 29-3. SCI Mode (Minimum Configuration) .....                                                      | 1624 |
| 29-4. SCI/LIN Interrupts .....                                                                    | 1631 |
| 29-5. Response Length Info Using IDBYTE Field Bits [5:4] for LIN Standards Earlier than 1.3 ..... | 1638 |
| 29-6. Response Length with SCIFORMAT[18:16] Programming .....                                     | 1638 |
| 29-7. Superfractional Bit Modulation for LIN Master Mode and Slave Mode .....                     | 1640 |
| 29-8. Timeout Values in $T_{bit}$ Units .....                                                     | 1647 |
| 29-9. SCI/LIN Control Registers.....                                                              | 1659 |
| 29-10. SCI Global Control Register 0 (SCIGCR0) Field Descriptions .....                           | 1660 |
| 29-11. SCI Global Control Register 1 (SCIGCR1) Field Descriptions .....                           | 1661 |
| 29-12. SCI Receiver Status Flags .....                                                            | 1664 |
| 29-13. SCI Transmitter Status Flags .....                                                         | 1664 |
| 29-14. SCI Global Control Register 2 (SCIGCR2) Field Descriptions .....                           | 1665 |
| 29-15. SCI Set Interrupt Register (SCISSETINT) Field Descriptions.....                            | 1666 |
| 29-16. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions.....                         | 1669 |
| 29-17. SCI Set Interrupt Level Register (SCISSETINTLVL) Field Descriptions.....                   | 1672 |
| 29-18. SCI Clear Interrupt Level Register (SCICLEARINTLVL) Field Descriptions.....                | 1675 |
| 29-19. SCI Flags Register (SCIFLR) Field Descriptions.....                                        | 1678 |
| 29-20. SCI Interrupt Vector Offset 0 (SCIINTVECT0) Field Descriptions .....                       | 1685 |
| 29-21. SCI Interrupt Vector Offset 1 (SCIINTVECT1) Field Descriptions .....                       | 1685 |
| 29-22. SCI Format Control Register (SCIFORMAT) Field Descriptions .....                           | 1686 |
| 29-23. Baud Rate Selection Register (BRS) Field Descriptions .....                                | 1687 |
| 29-24. Comparative Baud Values for Different P Values, Asynchronous Mode.....                     | 1688 |
| 29-25. Receiver Emulation Data Buffer (SCIED) Field Descriptions.....                             | 1688 |
| 29-26. Receiver Data Buffer (SCIRD) Field Descriptions .....                                      | 1689 |
| 29-27. Transmit Data Buffer Register (SCITD) Field Descriptions .....                             | 1690 |
| 29-28. SCI Pin I/O Control Register 0 (SCIPIO0) Field Descriptions .....                          | 1690 |
| 29-29. SCI Pin I/O Control Register 1 (SCIPIO1) Field Descriptions .....                          | 1691 |
| 29-30. LINTX Pin Control .....                                                                    | 1691 |
| 29-31. LINRX Pin Control .....                                                                    | 1691 |
| 29-32. SCI Pin I/O Control Register 2 (SCIPIO2) Field Descriptions .....                          | 1692 |
| 29-33. SCI Pin I/O Control Register 3 (SCIPIO3) Field Descriptions .....                          | 1693 |
| 29-34. SCI Pin I/O Control Register 4 (SCIPIO4) Field Descriptions .....                          | 1694 |
| 29-35. SCI Pin I/O Control Register 5 (SCIPIO5) Field Descriptions .....                          | 1695 |
| 29-36. SCI Pin I/O Control Register 6 (SCIPIO6) Field Descriptions .....                          | 1696 |
| 29-37. SCI Pin I/O Control Register 7 (SCIPIO7) Field Descriptions .....                          | 1697 |
| 29-38. SCI Pin I/O Control Register 8 (SCIPIO8) Field Descriptions .....                          | 1697 |
| 29-39. LIN Compare Register (LINCOMPARE) Field Descriptions .....                                 | 1698 |
| 29-40. LIN Receive Buffer 0 Register (LINRD0) Field Descriptions.....                             | 1699 |
| 29-41. LIN Receive Buffer 1 Register (RD1) Field Descriptions.....                                | 1699 |

|                                                                                    |      |
|------------------------------------------------------------------------------------|------|
| 29-42. LIN Mask Register (LINMASK) Field Descriptions .....                        | 1700 |
| 29-43. LIN Identification Register (LINID) Field Descriptions .....                | 1701 |
| 29-44. LIN Transmit Buffer 0 Register (LINTD0) Field Descriptions .....            | 1702 |
| 29-45. LIN Transmit Buffer 1 Register (LINTD1) Field Descriptions .....            | 1702 |
| 29-46. Maximum Baud Rate Selection Register (MBRS) Field Descriptions .....        | 1703 |
| 29-47. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions .....     | 1704 |
| 29-48. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins .....   | 1707 |
| 30-1. SCI Interrupts .....                                                         | 1718 |
| 30-2. DMA and Interrupt Requests in Multiprocessor Modes .....                     | 1719 |
| 30-3. SCI Control Registers Summary .....                                          | 1723 |
| 30-4. SCI Global Control Register 0 (SCIGCR0) Field Descriptions .....             | 1724 |
| 30-5. SCI Global Control Register 1 (SCIGCR1) Field Descriptions .....             | 1725 |
| 30-6. SCI Set Interrupt Register (SCISSETINT) Field Descriptions .....             | 1728 |
| 30-7. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions .....          | 1730 |
| 30-8. SCI Set Interrupt Level Register (SCISSETINTLVL) Field Descriptions .....    | 1732 |
| 30-9. SCI Clear Interrupt Level Register (SCICLEARINTLVL) Field Descriptions ..... | 1733 |
| 30-10. SCI Flags Register (SCIFLR) Field Descriptions .....                        | 1735 |
| 30-11. SCI Receiver Status Flags .....                                             | 1738 |
| 30-12. SCI Transmitter Status Flags .....                                          | 1738 |
| 30-13. SCI Interrupt Vector Offset 0 (SCIINTVECT0) Field Descriptions .....        | 1739 |
| 30-14. SCI Interrupt Vector Offset 1 (SCIINTVECT1) Field Descriptions .....        | 1739 |
| 30-15. SCI Format Control Register (SCIFORMAT) Field Descriptions .....            | 1740 |
| 30-16. Baud Rate Selection Register (BRS) Field Descriptions .....                 | 1741 |
| 30-17. Comparative Baud Values for Different P Values, Asynchronous Mode .....     | 1741 |
| 30-18. Receiver Emulation Data Buffer (SCIED) Field Descriptions .....             | 1742 |
| 30-19. Receiver Data Buffer (SCIRD) Field Descriptions .....                       | 1742 |
| 30-20. Transmit Data Buffer Register (SCITD) Field Descriptions .....              | 1743 |
| 30-21. SCI Pin I/O Control Register 0 (SCIPIO0) Field Descriptions .....           | 1743 |
| 30-22. SCI Pin I/O Control Register 1 (SCIPIO1) Field Descriptions .....           | 1744 |
| 30-23. SCITX Pin Control .....                                                     | 1744 |
| 30-24. SCIRX Pin Control .....                                                     | 1744 |
| 30-25. SCI Pin I/O Control Register 2 (SCIPIO2) Field Descriptions .....           | 1745 |
| 30-26. SCI Pin I/O Control Register 3 (SCIPIO3) Field Descriptions .....           | 1746 |
| 30-27. SCI Pin I/O Control Register 4 (SCIPIO4) Field Descriptions .....           | 1747 |
| 30-28. SCI Pin I/O Control Register 5 (SCIPIO5) Field Descriptions .....           | 1748 |
| 30-29. SCI Pin I/O Control Register 6 (SCIPIO6) Field Descriptions .....           | 1749 |
| 30-30. SCI Pin I/O Control Register 7 (SCIPIO7) Field Descriptions .....           | 1750 |
| 30-31. SCI Pin I/O Control Register 8 (SCIPIO8) Field Descriptions .....           | 1750 |
| 30-32. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions .....     | 1751 |
| 30-33. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins .....   | 1754 |
| 31-1. Ways to Generate a NACK Bit .....                                            | 1763 |
| 31-2. Interrupt Requests Generated by I2C Module .....                             | 1768 |
| 31-3. I2C Control Register Summary .....                                           | 1771 |
| 31-4. I2C Own Address Manager Register (I2COAR) Field Descriptions .....           | 1772 |
| 31-5. Correct Mode for Bits OA.9:0 .....                                           | 1772 |
| 31-6. I2C Interrupt Mask Register (I2CIMR) Field Descriptions .....                | 1773 |
| 31-7. I2C Status Register (I2CSTR) Field Descriptions .....                        | 1774 |
| 31-8. I2C Clock Divider Low Register (I2CCKL) Field Descriptions .....             | 1777 |
| 31-9. I2C Clock Control High Register (I2CCKH) Field Descriptions .....            | 1777 |

|                                                                                               |      |
|-----------------------------------------------------------------------------------------------|------|
| 31-10. I2C Data Count Register (I2CCNT) Field Descriptions .....                              | 1778 |
| 31-11. I2C Data Receive Register (I2CDRR) Field Descriptions .....                            | 1778 |
| 31-12. I2C Slave Address Register (I2CSAR) Field Descriptions .....                           | 1779 |
| 31-13. Correct Modes for Bits SA(9–0) .....                                                   | 1779 |
| 31-14. I2C Data Transmit Register (I2CDXR) Field Descriptions .....                           | 1779 |
| 31-15. I2C Mode Register (I2CMDR) Field Descriptions .....                                    | 1780 |
| 31-16. I2C Module Condition, Bus Activity, and Mode .....                                     | 1782 |
| 31-17. I2C Module Operating Modes .....                                                       | 1782 |
| 31-18. Number of Bits Sent on Bus .....                                                       | 1782 |
| 31-19. I2C Interrupt Vector Register (I2CIVR) Field Descriptions .....                        | 1783 |
| 31-20. Interrupt Codes for INTCODE Bit .....                                                  | 1783 |
| 31-21. I2C Extended Mode Register (I2CEMDR) Field Descriptions .....                          | 1784 |
| 31-22. I2C Prescale Register (I2CPSC) Field Descriptions .....                                | 1784 |
| 31-23. I2C Peripheral ID Register 1 (I2CPID1) Field Descriptions .....                        | 1785 |
| 31-24. I2C Peripheral ID Register 2 (I2CPID2) Field Descriptions .....                        | 1785 |
| 31-25. I2C DMA Control Register (I2CDMACR) Field Descriptions .....                           | 1786 |
| 31-26. I2C Pin Function Register (I2CPFNC) Field Descriptions .....                           | 1786 |
| 31-27. I2C Pin Direction Register (I2CPDIR) Field Descriptions .....                          | 1787 |
| 31-28. I2C Data Input Register (I2CDIN) Field Descriptions .....                              | 1787 |
| 31-29. I2C Data Output Register (I2CDOUT) Field Descriptions .....                            | 1788 |
| 31-30. I2C Data Set Register (I2CDSET) Field Descriptions .....                               | 1788 |
| 31-31. I2C Data Clear Register (I2CDSET) Field Descriptions .....                             | 1789 |
| 31-32. I2C Pin Open Drain Register (I2CPDR) Field Descriptions .....                          | 1789 |
| 31-33. I2C Pull Disable Register (I2CPDIS) Field Descriptions .....                           | 1790 |
| 31-34. I2C Pull Select Register (I2CPSEL) Field Descriptions .....                            | 1790 |
| 31-35. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins .....              | 1791 |
| 31-36. I2C Pins Slew Rate Select Register (I2CSRS) Field Descriptions .....                   | 1791 |
| 32-1. EMAC and MDIO Signals for MII Interface .....                                           | 1798 |
| 32-2. EMAC and MDIO Signals for RMII Interface .....                                          | 1799 |
| 32-3. MDIO Multiplexing Control .....                                                         | 1800 |
| 32-4. MII / RMII Multiplexing Control .....                                                   | 1800 |
| 32-5. Ethernet Frame Description .....                                                        | 1801 |
| 32-6. Basic Descriptor Description .....                                                      | 1803 |
| 32-7. Receive Frame Treatment Summary .....                                                   | 1828 |
| 32-8. Middle of Frame Overrun Treatment .....                                                 | 1829 |
| 32-9. Emulation Control .....                                                                 | 1839 |
| 32-10. EMAC Control Module Registers .....                                                    | 1840 |
| 32-11. EMAC Control Module Revision ID Register (REVID) Field Descriptions .....              | 1841 |
| 32-12. EMAC Control Module Software Reset Register (SOFTRESET) .....                          | 1841 |
| 32-13. EMAC Control Module Interrupt Control Register (INTCONTROL) .....                      | 1842 |
| 32-14. EMAC Control Module Receive Threshold Interrupt Enable Register (C0RXTHRESHEN) .....   | 1843 |
| 32-15. EMAC Control Module Receive Interrupt Enable Register (C0RXEN) .....                   | 1844 |
| 32-16. EMAC Control Module Transmit Interrupt Enable Register (C0TXEN) .....                  | 1845 |
| 32-17. EMAC Control Module Miscellaneous Interrupt Enable Register (C0MISCEN) .....           | 1846 |
| 32-18. EMAC Control Module Receive Threshold Interrupt Status Register (C0RXTHRESHSTAT) ..... | 1847 |
| 32-19. EMAC Control Module Receive Interrupt Status Register (C0RXSTAT) .....                 | 1848 |
| 32-20. EMAC Control Module Transmit Interrupt Status Register (C0TXSTAT) .....                | 1849 |
| 32-21. EMAC Control Module Miscellaneous Interrupt Status Register (C0MISCSTAT) .....         | 1850 |
| 32-22. EMAC Control Module Receive Interrupts Per Millisecond Register (C0RXIMAX) .....       | 1851 |

|                                                                                                                  |      |
|------------------------------------------------------------------------------------------------------------------|------|
| 32-23. EMAC Control Module Transmit Interrupts Per Millisecond Register (C0TXIMAX) .....                         | 1852 |

## 1.1 Designed for Safety Applications

The TMS570LS12x/11x device architecture has been designed from the ground up to simplify development of functionally safe systems. The basic architectural concept is known as a safe island approach. Power, clock, reset, and basic processing function are protected to a high level of diagnostic coverage in hardware. Some of the key features of the safe island region are:

- A dual core lockstep processing solution built around ARM® Cortex™-R4F CPU which detects failures at the core boundary on a cycle by cycle basis. Special measures in processor layout, clock distribution, power distribution, reset distribution, and temporal diversity are all implemented to mitigate common cause failures of the logical CPU and its checker.
- Hardware BIST controllers which provide an extremely high level of diagnostic coverage for the lockstep CPUs and SRAMs in the system, while executing faster and consuming less memory than equivalent software-based self-test solutions
- ECC on the SRAM and flash memories tightly coupled to the R4F. The ECC controllers are located inside the CPU. This approach has two key advantages:
  - The interconnect between CPU and the memory is also covered by the diagnostic
  - The ECC logic itself is checked on a cycle by cycle basis
- Onboard voltage and reset monitoring logic
- Onboard oscillator and PLL failure detection logic including a backup RC oscillator which can be utilized upon failure

The TMS570LS12x/11x device architecture also includes many features to simplify diagnostics of remaining logic such as:

- Continuous parity diagnostics on all peripheral memories
- Analog and digital loopback to test for shorts on I/O
- HW self-test and diagnostics on the ADC module to check integrity of both analog inputs and the ADC core conversion function
- A DMA driven hardware engine for the background calculation of CRC signatures during data transfers
- A centralized error reporting function including a status output pin to enable external monitoring of the device status

## 1.2 Family Description

The TMS570LS12x/11x integrates the ARM® Cortex™-R4F Floating Point CPU that offers an efficient 1.6 DMIPS/MHz and has configurations that can run up to 180MHz providing up to 288 DMIPS. The device supports the big-endian [BE32] format.

The TMS570LS12x/11x has up to 1.25MB integrated Flash and up to 192KB data RAM configurations with single bit error correction and double bit error detection. The flash memory on this device is a nonvolatile, electrically erasable and programmable memory implemented with a 64-bit-wide data bus interface. The flash operates on a 3.3V supply input (same level as I/O supply) for all read, program and erase operations. When in pipeline mode, the flash operates with a system clock frequency of up to 180MHz. The SRAM supports single-cycle read/write accesses in byte, halfword, and word modes.

The TMS570LS12x/11x device features peripherals for real-time control-based applications, including two Next Generation High End Timer (N2HET) timing coprocessors with up to 40 total IO terminals and a 12-bit A to D converter supporting up to 24 inputs.

The N2HET is an advanced intelligent timer that provides sophisticated timing functions for real-time applications. The timer is software-controlled, using a reduced instruction set, with a specialized timer micromachine and an attached I/O port. The N2HET can be used for pulse width modulated outputs, capture or compare inputs, or general-purpose I/O. It is especially well suited for applications requiring multiple sensor information and drive actuators with complex and accurate time pulses. A High End Timer Transfer Unit (HET-TU) can perform DMA type transactions to transfer N2HET data to or from main memory. A Memory Protection Unit (MPU) is built into the HET-TU.

The device has two 12-bit-resolution MibADCs with 24 total channels and 64 words of parity protected buffer RAM each. The MibADC channels can be converted individually or can be grouped by software for sequential conversion sequences. Sixteen channels are shared between the two MibADCs. There are three separate groupings. Each sequence can be converted once when triggered or configured for continuous conversion mode.

The device has multiple communication interfaces: three MibSPIs, up to two SPIs, one LIN, one SCI, three DCANs, one I<sup>2</sup>C, one Ethernet, and one FlexRay™ controller. The SPI provides a convenient method of serial interaction for high-speed communications between similar shift-register type devices. The LIN supports the Local Interconnect standard 2.0 and can be used as a UART in full-duplex mode using the standard Non-Return-to-Zero (NRZ) format. The DCAN supports the CAN 2.0B protocol standard and uses a serial, multimaster communication protocol that efficiently supports distributed real-time control with robust communication rates of up to 1 megabit per second (Mbps). The DCAN is ideal for applications operating in noisy and harsh environments (for example, automotive and industrial fields) that require reliable serial communication or multiplexed wiring. The FlexRay uses a dual channel serial, fixed time base multimaster communication protocol with communication rates of 10 megabits per second (Mbps) per channel. A FlexRay Transfer Unit (FTU) enables autonomous transfers of FlexRay data to and from main CPU memory. Transfers are protected by a dedicated, built-in Memory Protection Unit (MPU). The Ethernet module supports MII and MDIO interfaces.

The I2C module is a multi-master communication module providing an interface between the microcontroller and an I2C compatible device via the I2C serial bus. The I2C supports both 100 Kbps and 400 Kbps speeds.

The frequency-modulated phase-locked loop (FMPLL) clock module is used to multiply the external frequency reference to a higher frequency for internal use. The FMPLL provides one of the seven possible clock source inputs to the global clock module (GCM). The GCM module manages the mapping between the available clock sources and the device clock domains.

The device also has an external clock prescaler (ECP) module that when enabled, outputs a continuous external clock on the ECLK pin/ball. The ECLK frequency is a user-programmable ratio of the peripheral interface clock (VCLK) frequency. This low frequency output can be monitored externally as an indicator of the device operating frequency.

The Direct Memory Access Controller (DMA) has 16 channels, 32 control packets and parity protection on its memory. A Memory Protection Unit (MPU) is built into the DMA to protect memory against erroneous transfers.

The Error Signaling Module (ESM) monitors all device errors and determines whether an interrupt or external Error pin/ball is triggered when a fault is detected. The nERROR can be monitored externally as an indicator of a fault condition in the microcontroller.

The External Memory Interface (EMIF) provides a memory extension to asynchronous and synchronous memories or other slave devices.

The device supports all the built-in ARM Cortex™-R4F CoreSight™ debug features. In addition, a Parameter Overlay Module (POM) can re-route Flash accesses to internal memory or to external memory via the EMIF, thus avoiding the re-programming steps necessary for parameter updates in Flash.

With integrated safety features and a wide choice of communication and control peripherals, the TMS570LS12x/11x is an ideal solution for high performance real time control applications with safety critical requirements.

Figure 1-1. Block Diagram

## 1.3 Endianism Considerations

### 1.3.1 TMS570: Big Endian (BE32)

The TMS570 family is based on the ARM® Cortex™-R4F core. ARM has designed this core to be used in big-endian and little-endian systems. For the TI TMS570 family, the endianness has been configured to BE32. Big-endian systems store the most-significant byte of a multi-byte data field in the lowest memory address. Also, the address of the multi-byte data field is the lowest address. Below is an example of the physical addresses of individual bytes.

**Figure 1-2. Example: SPIDELAY – 0xFFFF7F448**

|                      |    |    |    |    |    |    |    |                      |    |    |    |    |    |    |    |
|----------------------|----|----|----|----|----|----|----|----------------------|----|----|----|----|----|----|----|
| 31                   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23                   | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| C2TDELAY[7:0]        |    |    |    |    |    |    |    | T2CDELAY[7:0]        |    |    |    |    |    |    |    |
| Byte 3 - 0xFFFF7F448 |    |    |    |    |    |    |    | Byte 2 - 0xFFFF7F449 |    |    |    |    |    |    |    |
| 15                   | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7                    | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| T2EDELAY[7:0]        |    |    |    |    |    |    |    | C2EDELAY[7:0]        |    |    |    |    |    |    |    |
| Byte 1 - 0xFFFF7F44A |    |    |    |    |    |    |    | Byte 0 - 0xFFFF7F44B |    |    |    |    |    |    |    |

32-bit accesses to this register should use the lowest address i.e. 0xFFFF7F448. Writing 0x11223344 to address 0xFFFF7F448 shows the following when viewing the memory in 8-bit and 32-bit modes.

As such the headers provided as part of HALCoGen do take the endianness into account and provide header structures that are agnostic to endianness. This is achieved by using C directives for the compiler that make use of the compile options configured for the project by the user (`__little_endian__` used in Code Composer Studio codegen tools). This directive may need to be adapted for other compilers.

```
#ifdef __little_endian__
    char C2EDELAY      : 8U; /**lt; 0xF448: CS to ENA      */
    char T2EDELAY      : 8U; /**lt; 0xF449: Transmit to ENA */
    char T2CDELAY      : 8U; /**lt; 0xF44A: Transmit to CS  */
    char C2TDELAY      : 8U; /**lt; 0xF44B: CS to Transmit */
#else
    char C2TDELAY      : 8U; /**lt; 0xF448: CS to Transmit */
    char T2CDELAY      : 8U; /**lt; 0xF449: Transmit to CS  */
    char T2EDELAY      : 8U; /**lt; 0xF44A: Transmit to ENA */
    char C2EDELAY      : 8U; /**lt; 0xF44B: CS to ENA      */
#endif
```

## Architecture

This chapter consists of five sections. The first section describes specific aspects of the device architecture. The second section describes the clocking structure of the microcontrollers. The third section gives an overview of the device memory organization. The fourth section details exceptions on the device, and the last section describes the system and peripheral control registers of the microcontroller.

## 2.1 Introduction

The TMS570LS12x/11x family of microcontrollers is based on the Texas Instruments TMS570 Architecture. This chapter describes specific aspects of the architecture as applicable to the TMS570LS12x/11x family of microcontrollers.

### 2.1.1 Architecture Block Diagram

The TMS570LS12x/11x microcontrollers are based on the TMS570 Platform architecture, which defines the interconnect between the bus masters and the bus slaves.

Figure 2-1 shows a high-level architectural block diagram for the superset microcontroller.

**Figure 2-1. Architectural Block Diagram**

## 2.1.2 Definitions of Terms

Table 2-1 provides a definition of terms used in the architectural block diagram.

**Table 2-1. Definition of Terms**

| Acronym / Term              | Full Form                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ECC                         | Error Correction Code                                        | This is a code that is used by the Single Error Correction Double Error Detection (SECCDED) logic inside the two Cortex-R4F processors (CPUs). There are 8 bits of ECC for every 64 bits of data accessed from the CPU tightly-coupled memories (flash and RAM).                                                                                                                              |
| Lockstep                    | –                                                            | This is the mode of operation of the dual ARM Cortex-R4F CPUs. The outputs of the two CPUs are compared on each CPU clock cycle. Any miscompare is flagged as an error of the highest severity level.                                                                                                                                                                                         |
| DMA                         | Direct Memory Access                                         | The DMA module is used for transferring 8-, 16-, 32- or 64-bit data across the entire device memory map. The DMA module is one of the bus masters on the device. That is, it can initiate a read or a write transaction.                                                                                                                                                                      |
| POM                         | Parameter Overlay Module                                     | The parameter overlay module redirects accesses to a programmable region in flash memory (read-only) to a RAM memory, either on-chip or via the external memory interface (EMIF). This allows a user to evaluate the impact of changing values of constants stored in the flash memory without actually having to erase and reprogram the flash. The POM is also a bus master in this device. |
| DAP                         | Debug Access Port                                            | The DAP allows a tool such as a debugger to read from or write to any region in the device memory map. The DAP is a bus master in this device.                                                                                                                                                                                                                                                |
| SCR1:AHB BMM                | AMBA High-performance Bus Matrix Module                      | The DMA, POM and DAP all act as masters on the AMBA High-performance Bus (AHB). The BMM arbitrates between concurrent accesses by these masters using a fixed priority scheme. The modules in descending order of priority are POM → DMA → DAP.                                                                                                                                               |
| HTUx                        | High-end timer Transfer Unit                                 | The HTU is a dedicated transfer unit for the New Enhanced High-End Timer module. The HTU has a native interface to the N2HET RAM, and is used to transfer data to and from the N2HET RAM from and to another region in the device memory-map. There is one HTU per N2HET module, so that there are 2 HTU modules on the device. The HTUx are bus masters in this device.                      |
| FTU                         | FlexRay Transfer Unit                                        | The FTU is a dedicated transfer unit for the FlexRay communication interface controller. The FTU has a native interface to the FlexRay message RAM and is used to transfer data to / from the FlexRay message RAM from / to another region in the device memory map. The FTU is a bus master in this device.                                                                                  |
| SCR2:VBUSP SCR              | VBUSP Switched Central Resource Controller                   | The SCR2 arbitrates between concurrent accesses by the HTUx and FTU modules. A round-robin priority scheme is used between the HTUx and FTU.                                                                                                                                                                                                                                                  |
| EMAC                        | Ethernet Media Access Controller                             | The EMAC has a dedicated DMA-type component that is used to transfer data to / from the EMAC descriptor memory from / to another memory in the device memory map. This DMA-type component of the EMAC is a bus master in this device.                                                                                                                                                         |
| SCR3:VBUSP SCR              | VBUSP Switched Central Resource Controller                   | The SCR3 arbitrates between concurrent accesses by the EMAC and another module that is not available in this configuration of the device.                                                                                                                                                                                                                                                     |
| VBUSM SCR                   | VBUSM Switched Central Resource Controller                   | This is the main device SCR. It arbitrates between the accesses from multiple bus masters to the bus slaves using a round robin priority scheme.                                                                                                                                                                                                                                              |
| CRC                         | Cyclic Redundancy Checker                                    | The CRC module provides two channels to perform background signature verification on any memory region. It also supports maximum-length Parallel Signature Analysis (PDS) based on a 64-bit primitive polynomial. The CRC module is a bus slave in this device.                                                                                                                               |
| EEPROM Emulation Flash Bank | Emulated Electrically Erasable Programmable Read-Only Memory | This is a flash bank that is dedicated for use as an emulated EEPROM. This device supports 64KB of flash for emulated EEPROM.                                                                                                                                                                                                                                                                 |
| SCR4: VBUSP SCR             | VBUSP Switched Central Resource Controller                   | The SCR4 is used to decode the accesses to the bus slaves for the EMAC and EMIF modules. SCR4 is a bus slave in this device.                                                                                                                                                                                                                                                                  |

**Table 2-1. Definition of Terms (continued)**

| Acronym / Term   | Full Form                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EMAC slaves      | Ethernet Media Access Controller slave ports | There are four EMAC slaves: <ol style="list-style-type: none"> <li>1. EMAC Control Module: this provides an interface between the EMAC and MDIO modules and the bus masters. It also includes 8KB of RAM to hold EMAC packet buffer descriptors.</li> <li>2. EMAC: The EMAC module interfaces to the other devices on the Ethernet Network using the Media Independent Interface (MII) or Reduced Media Independent Interface (RMII).</li> <li>3. Management Data Input / Output (MDIO): The MDIO module is used to manage the physical layer (PHY) device connected to the EMAC module.</li> <li>4. Communications Port Programming Interface (CPPI): This is the 8KB of RAM used to hold the EMAC packet buffer descriptors.</li> </ol> |
| EMIF slaves      | External Memory Interface slave ports        | There are five EMIF slaves:- External SDRAM memory: EMIF chip select 0- External asynchronous memories: EMIF chip selects 2, 3 and 4- EMIF module control and status registers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PCR              | Peripheral Central Resource controller       | The PCR manages the accesses to the peripheral registers and peripheral memories. It provides a global reset for all the peripherals. It also supports the capability to selectively enable or disable the clock for each peripheral individually. The PCR also manages the accesses to the system module registers required to configure the device's clocks, interrupts, etc. The system module registers also include status flags for indicating exception conditions – resets, aborts, errors, interrupts.                                                                                                                                                                                                                           |
| ADCx             | Analog-to-Digital Converter                  | The ADC uses the Successive Approximation Register architecture. It features a selectable 10-bit or 12-bit resolution. The ADC module also includes a RAM to hold the conversion results. A digital logic wrapper manages accesses to the control and status registers. There are two ADC modules on this device.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| N2HETx<br>N2HET1 | New Enhanced High-End Timer                  | The N2HET is an advanced intelligent timer that provides sophisticated timing functions for real-time applications. The timer is software-controlled, using a reduced instruction set, with a specialized timer micromachine and an attached I/O port. The N2HET can be used for pulse width modulated outputs, capture or compare inputs, or general-purpose I/O.                                                                                                                                                                                                                                                                                                                                                                        |
| GIO              | General-purpose Input/Output                 | The GIO module allows up to 16 terminals to be used as general-purpose Input or Output. Each of these are also capable of generating an interrupt to the CPU.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| DCANx            | Controller Area Network controller           | The DCAN supports the CAN 2.0B protocol standard and uses a serial, multi-master communication protocol that efficiently supports distributed real-time control with robust communication rates of up to 1 megabit per second (Mbps). The DCAN is ideal for applications operating in noisy and harsh environments (for example, automotive and industrial fields) that require reliable serial communication or multiplexed wiring.                                                                                                                                                                                                                                                                                                      |
| LIN              | Local Interconnect Network controller        | The LIN module supports the Local Interconnect standard revision 2.1 and can be used as a UART in full-duplex mode using the standard Non-Return-to-Zero (NRZ) format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| SCI              | Serial Communication Interface               | The SCI module supports the standard UART in full-duplex mode using the standard Non-Return-to-Zero (NRZ) format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| I2C              | Inter-Integrated Circuit controller          | The I2C module is a multi-master communication module providing an interface between the device and an I2C-compatible device via the I2C serial bus. The I2C supports both 100 Kbps and 400 Kbps speeds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| FlexRay          | FlexRay communication controller             | The FlexRay uses a dual channel serial, fixed time base multi-master communication protocol with communication rates of 10 megabits per second (Mbps) per channel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| SPIx             | Serial Peripheral Interface                  | The SPIx module provides a clocked serial communication interface for reliable communication between the device and other serial devices with the standard SPI interface. There are two SPI modules on this device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| MibSPIx          | Multi-Buffered Serial Peripheral Interface   | The MibSPIx modules also support the standard SPI communication protocol. The transfers are all grouped into transfer chunks called "transfer groups". These transfer groups are made up of one or more buffers in the MibSPIx RAM. The RAM is used to hold the control information and data to be transmitted, as well as the status information and data that is received. There are three MibSPI modules in this device.                                                                                                                                                                                                                                                                                                               |

**Table 2-1. Definition of Terms (continued)**

| Acronym / Term | Full Form                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ePWM           | Enhanced Pulse Width Modulator              | The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipments. These systems include digital motor control, switch mode power supply control, uninterruptible power supplies (UPS), and other forms of power conversion. The ePWM peripheral performs a digital to analog (DAC) function, where the duty cycle is equivalent to a DAC analog value; it is sometimes referred to as a Power DAC.    |
| eCAP           | Enhanced Capture Module                     | The enhanced Capture (eCAP) module is essential in systems where accurate timing of external events is important.                                                                                                                                                                                                                                                                                                                                                                                                 |
| eQEP           | Enhanced Quadrature Encoder Pulse Module    | The enhanced quadrature encoder pulse (eQEP) module is used for direct interface with a linear or rotary incremental encoder to get position, direction, and speed information from a rotating machine for use in a high-performance motion and position-control system.                                                                                                                                                                                                                                          |
| eFuse          | Electronically Programmable Fuse controller | Electrically programmable fuses (eFuses) are used to configure the device after deassertion of PORRST. The eFuse values are read and loaded into internal registers as part of the power-on-reset sequence. The eFuse values are protected with single bit error correction, double bit error detection (SECDED) codes. These fuses are programmed during the initial factory test of the device. The eFuse controller is designed so that the state of the eFuses cannot be changed once the device is packaged. |

### 2.1.3 Bus Master / Slave Access Privileges

This device implements some restrictions on the bus slave access privileges, see [Table 2-2](#), in order to improve the overall throughput of the interconnect shown in [Figure 2-1](#).

**Table 2-2. Bus Master / Slave Access Privileges**

| Bus Masters | Master Id | Bus Slaves Being Accessed          |                                       |             |                      |             |
|-------------|-----------|------------------------------------|---------------------------------------|-------------|----------------------|-------------|
|             |           | EEPROM Bank, ECC Bits, OTP Regions | Non-CPU Accesses to CPU Flash and RAM | CRC Module  | EMAC and EMIF Slaves | PCR Modules |
| CPU Read    | 0         | Allowed                            | Allowed                               | Allowed     | Allowed              | Allowed     |
| CPU Write   | 1         | Not allowed                        | Allowed                               | Allowed     | Allowed              | Allowed     |
| POM         | 2         | Allowed                            | Allowed                               | Allowed     | Allowed              | Allowed     |
| DMA         | 3         | Allowed                            | Allowed                               | Allowed     | Allowed              | Allowed     |
| DAP         | 5         | Allowed                            | Allowed                               | Allowed     | Allowed              | Allowed     |
| HTU1        | 6         | Not allowed                        | Allowed                               | Allowed     | Allowed              | Allowed     |
| FTU         | 7         | Not allowed                        | Allowed                               | Allowed     | Allowed              | Allowed     |
| HTU2        | 8         | Not allowed                        | Allowed                               | Allowed     | Allowed              | Allowed     |
| EMAC        | 9         | Not allowed                        | Allowed                               | Not allowed | Allowed              | Not allowed |

## 2.2 Memory Organization

### 2.2.1 Memory Map Overview

The Cortex-R4F uses a 32-bit address bus, giving it access to a memory space of 4GB. This space is divided into several regions, each addressed by different memory selects. Figure 2-2 shows the memory map of the microcontroller.

**Figure 2-2. Memory Map**

The main flash instruction memory is addressed starting at 0x00000000 by default. This is also the reset vector location – the ARM Cortex-R4F processor core starts execution from the reset vector address of 0x00000000 whenever the core gets reset.

The CPU data RAM is addressed starting at 0x08000000 by default.

The device also supports the swapping of the CPU instruction memory (flash) and data memory (RAM). This can be done by configuring the MEM SWAP field of the Bus Matrix Module Control Register 1 (BMMCR1).

After swapping, the data RAM is accessed starting from 0x00000000 and the RAM ECC locations are accessed starting from 0x00400000. The flash memory is now accessed starting from 0x08000000.

## 2.2.2 Memory Map Table

The control and status registers for each module are mapped within the CPU's 4GB memory space. Some modules also have associated memories, which are also mapped within this space.

Table 2-3 shows the starting and ending addresses of each module's register frame and any associated memory. The table also shows the response generated by the module or the interconnect whenever an access is made to an unimplemented location inside the register or memory frame.

**Table 2-3. Module Registers / Memories Memory Map**

| Name                                        | Memory Select      | Frame Address |             | Frame Size | Actual Size | Response for Access to Unimplemented Location in Frame |
|---------------------------------------------|--------------------|---------------|-------------|------------|-------------|--------------------------------------------------------|
|                                             |                    | Start         | End         |            |             |                                                        |
| CPU Tightly-Coupled Memories                |                    |               |             |            |             |                                                        |
| TCM Flash                                   | CS0                | 0x0000_0000   | 0x00FF_FFFF | 16MB       | 1.25MB      | Abort                                                  |
| TCM RAM + RAM ECC                           | CSRAM0             | 0x0800_0000   | 0x0BFF_FFFF | 64MB       | 192KB       |                                                        |
| Mirrored Flash                              | Flash mirror frame | 0x2000_0000   | 0x20FF_FFFF | 16MB       | 1.25MB      |                                                        |
| External Memory Accesses                    |                    |               |             |            |             |                                                        |

### 2.2.3 Flash on Microcontrollers

The TMS570LS12x/11x microcontrollers support up to 1.25MB of flash for use as program memory. The microcontrollers also support a separate 64KB flash bank for use as emulated EEPROM.

#### 2.2.3.1 Flash Bank Sectoring Configuration

The bank is divided into multiple sectors. A flash sector is the smallest region in the flash bank that must be erased. The sectoring configuration of each flash bank is shown in [Table 2-4](#).

**Table 2-4. Flash Memory Banks and Sectors <sup>(1)</sup>**

| Memory Arrays (or Banks) | Block Number | Sector Number | Segment    | Low Address | High Address |
|--------------------------|--------------|---------------|------------|-------------|--------------|
| BANK0 (1.25MBytes)       | 0            | 0             | 16K Bytes  | 0x0000_0000 | 0x0000_3FFF  |
|                          |              | 1             | 16K Bytes  | 0x0000_4000 | 0x0000_7FFF  |
|                          |              | 2             | 16K Bytes  | 0x0000_8000 | 0x0000_BFFF  |
|                          |              | 3             | 16K Bytes  | 0x0000_C000 | 0x0000_FFFF  |
|                          |              | 4             | 16K Bytes  | 0x0001_0000 | 0x0001_3FFF  |
|                          |              | 5             | 16K Bytes  | 0x0001_4000 | 0x0001_7FFF  |
|                          |              | 6             | 32K Bytes  | 0x0001_8000 | 0x0001_FFFF  |
|                          | 1            | 7             | 128K Bytes | 0x0002_0000 | 0x0003_FFFF  |
|                          |              | 8             | 128K Bytes | 0x0004_0000 | 0x0005_FFFF  |
|                          | 2            | 9             | 128K Bytes | 0x0006_0000 | 0x0007_FFFF  |
|                          |              | 10            | 128K Bytes | 0x0008_0000 | 0x0009_FFFF  |
|                          | 3            | 11            | 128K Bytes | 0x000A_0000 | 0x000B_FFFF  |
|                          |              | 12            | 128K Bytes | 0x000C_0000 | 0x000D_FFFF  |
|                          | 4            | 13            | 128K Bytes | 0x000E_0000 | 0x000F_FFFF  |
|                          |              | 14            | 128K Bytes | 0x0010_0000 | 0x0011_FFFF  |
|                          |              | 15            | 128K Bytes | 0x0012_0000 | 0x0013_FFFF  |

<sup>(1)</sup>

- The Flash banks are 144-bit wide bank with ECC support.
- The flash bank7 can be programmed while executing code from flash bank0.
- Code execution is not allowed from flash bank7.

**Table 2-4. Flash Memory Banks and Sectors <sup>(1)</sup> (continued)**

| Memory Arrays<br>(or Banks)              | Block<br>Number | Sector<br>Number | Segment   | Low Address | High Address |

Refer to the device datasheet for electrical and timing specifications related to the flash module.

### 2.2.3.2 ECC Protection for Flash Accesses

The TMS570LS12x/11x microcontrollers protect all accesses to the on-chip flash memory by dedicated Single-Error-Correction-Double-Error-Detection (SECDED) logic.

The access to the program memory – flash bank 0, is protected by SECDED logic implemented inside the ARM Cortex-R4F CPU. Accesses to the EEPROM emulation flash bank (bank 7) are protected by dedicated SECDED logic inside the digital interface to the flash banks.

Both the SECDED logic implementations use Error Correction Codes (ECC) for correcting single-bit errors and for detecting multiple-bit errors in the values read from the flash arrays. There is an 8-bit ECC for every 64 bits of data. The ECC for the flash memory contents needs to be calculated by an external tool such as nowECC. The ECC can then be programmed into the flash array along with the actual application code.

The ECC for the flash array is stored in the flash itself, and is mapped to a region starting at 0xF0400000 for the main flash bank 0, and to a region starting at 0xF0100000 for the EEPROM emulation flash bank 7.

---

**NOTE: ECC Protection Not Enabled By Default**

The SECDED logic inside the CPU is not enabled by default and must be enabled by the application.

---

#### **Code Example for Enabling ECC Protection for Main Flash Accesses:**

The following code example can be used to enable the ECC protection for accesses to the main flash array:

```
MRC p15, #0, r1, c1, c0, #1
ORR r1, r1, #0x02000000      ;Enable ECC checking for ATCM
DMB
MCR p15, #0, r1, c1, c0, #1
```

The ECC protection for accesses to the EEPROM emulation flash bank can be enabled by writing 0xA to the EDACEN field of the flash module's Error Correction Control Register 1 (FEDACCTRL1). See [Chapter 5](#) for more details.

When the CPU detects an ECC single-, or double-bit error on a read from the flash memory, it signals this on a dedicated “Event” bus. This event bus signaling is also not enabled by default and must be enabled by the application. The following code example can be used to enable the CPU event signaling:

```
MRC p15,#0,r1,c9,c12,#0      ;Enabling Event monitor states
ORR r1, r1, #0x00000010
MCR p15,#0,r1,c9,c12,#0      ;Set 4th bit ('X') of PMNC register
MRC p15,#0,r1,c9,c12,#0
```

The digital logic that interfaces the ARM Cortex-R4F CPU to the flash banks captures the ECC error events signaled by the CPU, and in turn generates error signals that are input to the central Error Signaling Module (ESM).

## 2.2.4 On-Chip SRAM

Several SRAM modules are implemented on the device to support the functionality of the modules included.

Reads from the CPU data RAM are protected by ECC calculated inside the CPU. Reads from all other memories are protected by configurable odd or even parity that is evaluated in parallel with the actual read.

The TMS570LS12x/11x microcontrollers are targeted towards safety-critical applications, and it is critical for any failures in the on-chip SRAM modules to be identified before these modules are used for safety-critical functions. These microcontrollers support a Programmable Built-In Self-Test (PBIST) mechanism that is used to test each on-chip SRAM module for faults. The PBIST is usually run on device start-up as it is a destructive test and all contents of the tested SRAM module are overwritten during the test.

The microcontrollers also support a hardware-based auto-initialization of on-chip SRAM modules. This process also takes into account the read protection scheme implemented for each SRAM module – ECC or parity.

TI recommends that the PBIST routines be executed on the SRAM modules prior to the auto-initialization. The following section describe these two processes.

### 2.2.4.1 PBIST RAM Grouping and Algorithm Mapping For On-Chip SRAM Modules

Table 2-5 shows the groupings of the various on-chip memories for PBIST. It also lists the memory types and their assigned RAM Group Select (RGS) and Return Data Select (RDS). See Chapter 7 for more details on the usage of the RGS and RDS information.

**Table 2-5. PBIST Memory Grouping**

| Memory    | RAM Group # | Memory Type | RGS | RDS      |
|-----------|-------------|-------------|-----|----------|
| PBIST_ROM | 1           | ROM         | 1   | 0        |
| STC_ROM   | 2           | ROM         | 2   | 0        |
| DCAN1     | 3           | Dual-port   | 3   | 0 .. 5   |
| DCAN2     | 4           | Dual-port   | 4   | 0 .. 5   |
| DCAN3     | 5           | Dual-port   | 5   | 0 .. 5   |
| ESRAM1    | 6           | Single-port | 6   | 0/1 .. 4 |
| MIBSPI1   | 7           | Dual-port   | 7   | 0 .. 3   |
| MIBSPI3   | 8           | Dual-port   | 7   | 4 .. 7   |
| MIBSPI5   | 9           | Dual-port   | 7   | 8 .. 11  |
| VIM       | 10          | Dual-port   | 8   | 0 .. 1   |
| MIBADC1   | 11          | Dual-port   | 9   | 0        |
| DMA       | 12          | Dual-port   | 10  | 0 .. 5   |
| N2HET1    | 13          | Dual-port   | 11  | 0 .. 11  |
| HET TU1   | 14          | Dual-port   | 12  | 0 .. 5   |
| FLEXRAY   | 16          | Dual-port   | 14  | 0 .. 13  |
|           | 17          | Single-port |     |          |
| MIBADC2   | 18          | Dual-port   | 15  | 0        |
| N2HET2    | 19          | Dual-port   | 16  | 0 .. 11  |
| HET TU2   | 20          | Dual-port   | 17  | 0 .. 5   |
| ESRAM5    | 21          | Single-port | 18  | 0/1 .. 4 |
| ESRAM6    | 22          | Single-port | 19  | 0/1 .. 4 |
| ETHERNET  | 23          | Dual-port   | 20  | 0 .. 6   |
|           | 24          | Dual-port   |     |          |
|           | 25          | Single-port |     |          |

**Table 2-6** maps the different algorithms supported in application mode for the RAM groups. The table also lists the background pattern options available for each algorithm.

**Table 2-6. PBIST Algorithm Mapping**

| No. | ALGO MASK Register Value | Algorithm             | Memories Tested | Available Background Patterns                              | Valid RAM Groups                                     | Valid RAMINFO Register Value |
|-----|--------------------------|-----------------------|-----------------|------------------------------------------------------------|------------------------------------------------------|------------------------------|

---

**NOTE: Recommended Memory Test Algorithm**

March13 is the most recommended algorithm for the memory self-test.

---

For HCLK = 180 MHz, VCLK = 90 MHz, PBIST ROM\_CLK = 90 MHz, the March13 algorithm takes 14.02 ms to run on all on-chip SRAMs.

### 2.2.4.2 Auto-Initialization of On-Chip SRAM Modules

The device system provides the capability to perform a hardware initialization on most memories on the system bus and on the peripheral bus. The memory used for the FlexRay message objects is not directly CPU addressable, hence there is no memory auto-initialization support for this memory.

The intent of having the hardware initialization is to program the memory arrays with error detection capability to a known state based on their error detection scheme – odd/even parity or ECC. For example, the contents of the CPU data RAM after power-on reset is unknown. A hardware auto-initialization can be started so that there is no ECC error.

---

**NOTE: Effect of ECC or Parity on Memory Auto-Initialization**

The ECC or parity should be enabled on the RAMs before hardware auto-initialization starts if parity or ECC is being used.

---

**Auto-Initialization Sequence:**

1. Enable the global hardware memory initialization key by programming 0xA into MINITGCR[3:0], the Memory Initialization Key field (MINITGENA) of the Memory Hardware Initialization Global Control Register (MINITGCR) register.
2. Select the module on which the memory hardware initialization has to be performed by programming the appropriate value into the MSINENA(31–0) bits in the MSINENA register. See [Table 2-7](#).
3. If the global auto-initialization scheme is enabled, the corresponding module will initialize its memories based on its memory error checking scheme (even parity or odd parity or ECC).
4. When the memory initialization is complete, the module will signal “memory initialization done”, which sets the corresponding bit in the system module MIDONE field of the MINISTAT register to indicate the completion of its memory initialization.
5. When the memory hardware initialization completes for all modules, (indicated by each module’s MIDONE bit being set), the memory hardware initialization done bit (MINIDONE) is set in the MSTCGSTAT register.

**Table 2-7. Memory Initialization Select Mapping** <sup>(1)(2)(3)</sup>

| Memory         | Address Range |              | MSINENA Register Bit # |
|----------------|---------------|--------------|------------------------|
|                | Start         | End          |                        |
| RAM (PD#1)     | 0x08000000    | 0x08013FFF   | 0                      |
| RAM (RAM_PD#1) | 0x08010000    | 0x0801FFFF   | 0                      |
| RAM (RAM_PD#2) | 0x08020000    | 0x0802FFFF   | 0                      |
| MIBSPI5 RAM    | 0xFF0A0000    | 0xFF0BFFFF   | 12 <sup>(4)</sup>      |
| MIBSPI3 RAM    | 0xFF0C0000    | 0xFF0DFFFF   | 11 <sup>(4)</sup>      |
| MIBSPI1 RAM    | 0xFF0E0000    | 0xFF0FFFFFFF | 7 <sup>(4)</sup>       |
| DCAN3 RAM      | 0xFF1A0000    | 0xFF1BFFFF   | 10                     |
| DCAN2 RAM      | 0xFF1C0000    | 0xFF1DFFFF   | 6                      |
| DCAN1 RAM      | 0xFF1E0000    | 0xFF1FFFFFFF | 5                      |
| MIBADC2 RAM    | 0xFF3A0000    | 0xFF3BFFFF   | 14                     |
| MIBADC1 RAM    | 0xFF3E0000    | 0xFF3FFFFFFF | 8                      |
| NHET2 RAM      | 0xFF440000    | 0xFF47FFFF   | 15                     |
| NHET1 RAM      | 0xFF460000    | 0xFF47FFFF   | 3                      |
| HET TU2 RAM    | 0xFF4C0000    | 0xFF4DFFFF   | 16                     |
| HET TU1 RAM    | 0xFF4E0000    | 0xFF4FFFFFFF | 4                      |
| DMA RAM        | 0xFFF80000    | 0xFFF80FFF   | 1                      |
| VIM RAM        | 0xFFF82000    | 0xFFF82FFF   | 2                      |
| FlexRay TU RAM | 0xFF500000    | 0xFF51FFFF   | 13                     |

<sup>(1)</sup> If ECC protection is enabled for the CPU data RAM, then the auto-initialization process also initializes the corresponding ECC space.

<sup>(2)</sup> If parity protection is enabled for the peripheral SRAM modules, then the parity bits will also be initialized along with the SRAM modules.

<sup>(3)</sup> The CPU RAM interface module has separate control bit-fields to select the memory power domain that is to be initialized.

<sup>(4)</sup> The MibSPiX modules perform an initialization of the transmit and receive RAMs as soon as the multi-buffered mode is enabled. This is independent of whether the application has already initialized these RAMs using the auto-initialization method or not. The MibSPiX modules need to be released from reset by writing 1 to their SPIGCR0 registers before starting auto-initialization on their respective RAMs.

## 2.3 Exceptions

An “Exception” is an event that makes the processor temporarily halt the normal flow of program execution, for example, to service an interrupt from a peripheral. Before attempting to handle an exception, the processor preserves the critical parts of the current processor state so that the original program can resume when the handler routine has finished.

The following sections describe three exceptions – Reset, Abort and the System Software Interrupts.

Please refer to the ARM Cortex-R4F Technical Reference Manual for complete details on all exceptions.

### 2.3.1 Resets

The TMS570LS12x/11x microcontroller can be reset by either of the conditions described in [Table 2-8](#). Each reset condition is indicated in the System Exception Status Register (SYSESR).

The device nRST terminal is an I/O. It can be driven low by an external circuit to force a warm reset on the microcontroller. This terminal will be driven low as an output for a minimum of 8 peripheral clock (VCLK) cycles for any device system reset condition. As a result the EXT RST bit in the SYSESR register, SYSESR[3], gets set for all reset conditions listed in [Table 2-8](#). The nRST is driven low as an output for a longer duration during device power-up or whenever the power-on reset (nPORRST) is driven low externally. Refer the device datasheet for the electrical and timing specifications for the nRST.

**Table 2-8. Causes of Resets**

| Condition                          | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Driving nPORRST pin low externally | Cold reset, or power-on reset. This reset signal is typically driven by an external voltage supervisor. This reset is flagged by the PO RST bit in the SYSESR register, SYSESR[15].                                                                                                                                                                                                                                      |
| Voltage Monitor reset              | The microcontroller has an embedded voltage monitor that generates a power-on reset when the core voltage gets out of a valid range, or when the I/O voltage falls below a threshold. This reset is also flagged by the PO RST bit in the SYSESR register, SYSESR[15].<br><b>Note:</b> The voltage monitor is not an alternative for an external voltage supervisor.                                                     |
| Driving nRST pin low externally    | Warm reset. This reset input is typically used in a system with multiple ICs and which requires that the microcontroller also gets reset whenever the other IC detects a fault condition. This reset is flagged by the EXT RST bit in the SYSESR, register SYSESR[3].                                                                                                                                                    |
| Oscillator failure                 | This reset is generated by the system module when the clock monitor detects an oscillator fail condition. Whether or not a reset is generated is also dictated by a register in the system module. This reset is flagged by the OSC RST bit in the SYSESR register, SYSESR[14].                                                                                                                                          |
| Software reset                     | This reset is generated by the application software writing a 1 to bit 15 of System Exception Control Register (SYSECR) or a 0 to bit 14 of SYSECR. It is typically used by a bootloader type of code that uses a software reset to allow the code execution to branch to the application code once it is programmed into the program memory. This reset is flagged by the SW RST bit of the SYSESR register, SYSESR[4]. |
| CPU reset                          | This reset is generated by the CPU self-test controller (LBIST) or by changing the memory protection (MMU/MPU) configuration in the CPURSTCR register. This reset is flagged by the CPU RST bit of the SYSESR register, SYSESR[5].                                                                                                                                                                                       |
| Debug reset                        | The ICEPICK logic implemented on the microcontroller allows a system reset to be generated via the debug logic. This reset is flagged by the DBG RST bit of the SYSESR register, SYSESR[13].                                                                                                                                                                                                                             |
| Watchdog reset                     | This reset is generated by the digital windowed watchdog (DWWD) module on the microcontroller. The DWWD can generate a reset whenever the watchdog service window is violated. This reset is also flagged by bit 13 of the SYSESR register, SYSESR[13].                                                                                                                                                                  |

### 2.3.2 Aborts

When the ARM Cortex-R4F processor's memory system cannot complete a memory access successfully, an abort is generated. An error occurring on an instruction fetch generates a **prefetch abort**. Errors occurring on data accesses generate **data aborts**. Aborts are also categorized as being either **precise** or **imprecise**.

### 2.3.2.1 Prefetch Aborts

When a Prefetch Abort (PABT) occurs, the processor marks the prefetched instruction as invalid, but does not take the exception until the instruction is to be executed. If the instruction is not executed, for example because a branch occurs while it is in the pipeline, the abort does not take place.

All prefetch aborts are precise aborts.

### 2.3.2.2 Data Aborts

An error occurring on a data memory access can generate a data abort. If the instruction generating the memory access is not executed, for example, because it fails its condition codes, or is interrupted, the data abort does not take place.

A Data Abort (DABT) can be either precise or imprecise, depending on the type of fault that caused it.

### 2.3.2.3 Precise Aborts

A precise abort, also known as a synchronous abort, is one for which the exception is guaranteed to be taken on the instruction that generated the aborting memory access. The abort handler can use the value in the Link Register (r14\_abt) to determine which instruction generated the abort, and the value in the Saved Program Status Register (SPSR\_abt) to determine the state of the processor when the abort occurred.

### 2.3.2.4 Imprecise Aborts

An imprecise abort, also known as an asynchronous abort, is one for which the exception is taken on a later instruction to the instruction that generated the aborting memory access. The abort handler cannot determine which instruction generated the abort, or the state of the processor when the abort occurred. Therefore, imprecise aborts are normally fatal.

Imprecise aborts can be generated by store instructions to normal-type or device-type memory. When the store instruction is committed, the data is normally written into a buffer that holds the data until the memory system has sufficient bandwidth to perform the write access. This gives read accesses higher priority. The write data can be held in the buffer for a long period, during which many other instructions can complete. If an error occurs when the write is finally performed, this generates an imprecise abort.

The TMS570LS12x/11x microcontroller architecture applies techniques at the system level to mitigate the impact of imprecise aborts. System level adoption of write status sidebands to the data path allow bus masters to comprehend imprecise aborts, turning them into precise aborts. In cases where this approach is not feasible, buffering bridges or other sources of imprecision may build a FIFO of current transactions such that an imprecise abort may be registered at the point of imprecision for later analysis.

#### **Masking Of Imprecise Aborts:**

The nature of imprecise aborts means that they can occur while the processor is handling a different abort. If an imprecise abort generates a new exception in such a situation, the banked link register (R14\_abt) and the Saved Processor Status Register (SPSR\_abt) values are overwritten. If this occurs before the data is pushed to the stack in memory, the state information about the first abort is lost. To prevent this from happening, the Current Processor Status Register (CPSR) contains a mask bit to indicate that an imprecise abort cannot be accepted, the A-bit. When the A-bit is set, any imprecise abort that occurs is held pending by the processor until the A-bit is cleared, when the exception is actually taken. The A-bit is automatically set when abort, IRQ or FIQ exceptions are taken, and on reset. The application must only clear the A-bit in an abort handler after the state information has either been stacked to memory, or is no longer required.

---

**NOTE: Default Behavior for Imprecise Aborts**

The A-bit in the CPSR is set by default. This means that no imprecise abort exception will occur. The application must enable imprecise abort exception generation by clearing the A-bit of the CPSR.

---

### 2.3.2.5 Conditions That Generate Aborts

An Abort is generated under the following conditions on the TMS570LS12x/11x microcontrollers.

- Access to an illegal address (a nonimplemented address)
- Access to a protected address (protection violation)
- Parity / ECC / Time-out Error on a valid access

#### Illegal Addresses:

The illegal addresses and the responses to an access to these addresses are defined in [Table 2-3](#).

#### Addresses Protected By MPU:

Memory access permissions can be configured via the ARM Cortex-R4F processor's Memory Protection Unit (MPU). Please refer to the ARM Cortex-R4F TRM for more details on the MPU configuration.

A memory access violation is logged as a permission fault in the CPU's fault status register and the virtual address of the access is logged into the CPU's fault address register.

#### Protection of Peripheral Register and Memory Frames:

Accesses to the peripheral register and memory frames can be protected either by configuring the MPU or by configuring the Peripheral Central Resource (PCR) controller registers.

The PCR module PPROTSETx registers contain one bit per peripheral select quadrant. These bits define the access permissions to the peripheral register frames. If the CPU attempts to write to a peripheral register for which it does not have the correct permissions, a protection violation is detected and an Abort occurs.

Some modules also enforce register updates to only be allowed when the CPU is in a privileged mode of operation. If the CPU writes to these registers in user mode, the writes are ignored.

The PCR module PMPROTSETx registers contain one bit per peripheral memory frame. These bits define the access permissions to the peripheral memory frames. If the CPU attempts to write to a peripheral memory for which it does not have the correct permissions, a protection violation is detected and an Abort occurs.

---

**NOTE: No Access Protection for Reads**

The PCR PPROTSETx and PMPROTSETx registers protect the peripheral registers and memories against illegal writes by the CPU. The CPU can read from the peripheral registers and memories in both user and privileged modes.

---

### 2.3.3 System Software Interrupts

The system module provides the capability of generating up to four software interrupts. A software interrupt is generated by writing the correct key value to either of the four System Software Interrupt Registers (SSIRx). The SSI registers also allow the application to provide a label for that software interrupt. This label is an 8-bit value that can then be used by the interrupt service routine to perform the required task based on the value provided. The source of the system software interrupt is reflected in the system software interrupt vector (SSIVEC) register.

## 2.4 Clocks

This section describes the clocking structure of the TMS570LS12x/11x microcontrollers.

### 2.4.1 Clock Sources

The devices support up to 7 clock sources. These are shown in [Table 2-9](#). The electrical specifications as well as timing requirements for each of the clock sources are specified in the device datasheet.

**Table 2-9. Clock Sources**

| Clock Source # | Clock Source Name           | Description                                                                                                                                                                                                                             |
|----------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | OSCIN                       | Main oscillator. This is the primary clock for the microcontroller and is the only clock that is input to the phase-locked loops. The oscillator frequency must be between 5 and 20 MHz.                                                |
| 1              | PLL #1                      | This is the output of the main PLL. The PLL is capable of modulating its output frequency in a controlled manner to reduce the radiated emissions.                                                                                      |
| 2              | Not implemented             | This clock source is not available and must not be enabled or used as source for any clock domain.                                                                                                                                      |
| 3              | EXTCLKIN1                   | External clock input 1. A square wave input can be applied to this device input and used as a clock source inside the device.                                                                                                           |
| 4              | LF LPO (Low Frequency LPO)  | This is the low-frequency output of the internal reference oscillator. This is typically an 80 KHz signal which is used by the real-time interrupt module for generating periodic interrupts to wake up from a low power mode.          |
| 5              | HF LPO (High Frequency LPO) | This is the high-frequency output of the internal reference oscillator. This is typically a 10 MHz signal which is used by the clock monitor module as a reference clock to monitor the main oscillator frequency.                      |
| 6              | PLL #2                      | This is the output of the second PLL. There is no option of modulating this PLL's output signal. This separate non-modulating PLL allows the generation of an asynchronous clock source that is independent of the CPU clock frequency. |
| 7              | EXTCLKIN2                   | External clock input 2. A square wave input can be applied to this device input and used as a clock source inside the device.                                                                                                           |

#### 2.4.1.1 Enabling / Disabling Clock Sources

Each clock source can be independently enabled or disabled using the set of Clock Source Disable registers – CSDIS, CSDISSET and CSDISCLR.

Each bit in these registers corresponds to the clock source number indicated in [Table 2-9](#). For example, setting bit 1 in the CSDIS or CSDISSET registers disables the PLL#1.

##### **NOTE: Disabling the Main Oscillator or HF LPO**

By default, the clock monitoring circuit is enabled and checks for the main oscillator frequency to be within a certain range using the HF LPO as a reference. If the main oscillator and/or the HF LPO are disabled with the clock monitoring still enabled, the clock monitor will indicate an oscillator fault. The clock monitoring must be disabled before disabling the main oscillator or the HF LPO clock source(s).

The clock source is only disabled once there is no active clock domain that is using that clock source. Also, see [Chapter 10](#) for more information on enabling/disabling the oscillator and PLL.

On the TMS570LS12x/11x microcontrollers, the clock sources 0, 4 and 5 are enabled by default.

#### 2.4.1.2 Checking for Valid Clock Sources

The application can check whether a clock source is valid or not by checking the corresponding bit to be set in the Clock Source Valid Status (CSVSTAT) register. For example, the application can check if bit 1 in CSVSTAT is set before using the output of PLL#1 as the source for any clock domain.

## 2.4.2 Clock Domains

The clocking on this device is divided into multiple clock domains for flexibility in control as well as clock source selection. There are 10 clock domains on this device. Each of these are described in [Table 2-10](#).

Each of the control registers listed in [Table 2-10](#) are defined in [Section 2.5](#). The AC timing characteristics for each clock domain are specified in the device datasheet.

**Table 2-10. Clock Domains**

| Clock Domain # | Clock Domain | Default Source | Source Selection Register | Special Considerations                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------|--------------|----------------|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | GCLK         | OSCIN          | GHVSR                     | <ul style="list-style-type: none"> <li>• Clock domain used by one of the two Cortex-R4F CPUs operating in lock-step</li> <li>• Always the same frequency as HCLK</li> <li>• In phase with HCLK</li> <li>• Is disabled separately from HCLK via the CDDISx registers bit 0</li> <li>• Can be divided by 1 up to 8 when running CPU selftest (LBIST) using the CLKDIV field of the STCCLKDIV register at address 0xFFFFE108</li> </ul> |
| 0              | GCLK2        | OSCIN          | GHVSR                     | <ul style="list-style-type: none"> <li>• Clock domain used by the second Cortex-R4F CPU operating in lock-step</li> <li>• Always the same frequency as GCLK</li> <li>• 2 cycles delayed from GCLK</li> <li>• Is disabled along with GCLK</li> <li>• Gets divided by the same divider setting as that for GCLK when running CPU selftest (LBIST)</li> </ul>                                                                           |
| 1              | HCLK         | OSCIN          | GHVSR                     | <ul style="list-style-type: none"> <li>• Clock domain used by the high-speed system modules: Flash memory interfaces, TCRAM interface, Error Signaling Module (ESM), DMA</li> <li>• Is disabled via the CDDISx registers bit 1</li> </ul>                                                                                                                                                                                            |
| 2              | VCLK         | OSCIN          | GHVSR                     | <ul style="list-style-type: none"> <li>• Clock domain used by some system modules (VIM), peripheral modules accessed via the Peripheral Central Resource (PCR) controller, and all other register interfaces also accessed via the PCR</li> <li>• Divided down from HCLK</li> <li>• Can be HCLK/1, HCLK/2,... or HCLK/16</li> <li>• Is disabled separately from HCLK via the CDDISx registers bit 2</li> </ul>                       |

| 6              | RTICKL       | VCLK           | RCLKSRC                   | <ul style="list-style-type: none"> <li>Clock domain dedicated for timebase generation in the Real-Time Interrupt (RTI) generation module</li> <li>Defaults to VCLK as the source</li> <li>If a clock source other than VCLK is selected for RTICKL, then the RTICKL frequency must be less than or equal to VCLK/3</li> <li>Application can ensure this by programming the RTI1DIV field of the RCLKSRC register, if necessary</li> <li>Is disabled via the CDDISx registers bit 6</li> </ul> |

### 2.4.2.1 Enabling / Disabling Clock Domains

Each clock domain can be independently enabled or disabled using the set of Clock Domain Disable registers – CDDIS, CDDISSET and CDDISCLR.

Each bit in these registers corresponds to the clock domain number indicated in [Table 2-10](#). For example, setting bit 1 in the CDDIS or CDDISSET registers disables the HCLK clock domain. The clock domain will be turned off only when every module that uses the HCLK domain gives the “permission” for HCLK to be turned off.

All clock domains are enabled by default, or upon a system reset, or whenever a wake up condition is detected.

### 2.4.2.2 Mapping Clock Sources to Clock Domains

Each clock domain needs to be mapped to a valid clock source. There are control registers that allow an application to choose the clock sources for each clock domain.

#### • **Selecting clock source for GCLK, HCLK and VCLKx domains**

The CPU clock (GCLK), the system module clock (HCLK), and the peripheral bus clocks (VCLKx) all use the same clock source. This clock source is selected via the GHVSR register. The default source for the GCLK, HCLK and VCLKx is the main oscillator. That is, after power up, the GCLK and HCLK are running at the OSCIN frequency, while the VCLKx frequency is the OSCIN frequency divided by 2.

#### • **Selecting clock source for VCLKA1 and VCLKA2 domains**

The clock source for VCLKA1 and VCLKA2 domains is selected via the VCLKASRC register. The default source for the VCLKA1 and VCLKA2 domains is the VCLK.

#### • **Selecting clock source for VCLKA4 domain**

The clock source for VCLKA4 domain is selected via the VCLKACON1 register. The default source for the VCLKA4 domain is the VCLK.

- **Selecting clock source for RTICK domain**

The clock source for RTICK domain is selected via the RCLKSRC register. The default source for the RTICK domain is the VCLK.

---

**NOTE: Selecting a clock source for RTICK that is not VCLK**

When the application chooses a clock source for RTICK domain that is not VCLK, then the application must ensure that the resulting RTICK frequency must be less than or equal to VCLK frequency divided by 3. The application can configure the RT1DIV field of the RCLKSRC register for dividing the selected clock source frequency by 1, 2, 4 or 8 to meet this requirement.

---

### 2.4.3 Low Power Modes

All clock domains are active in the normal operating mode. This is the default mode of operation. As described in [Section 2.4.1.1](#) and [Section 2.4.2.1](#), the application can choose to disable any particular clock source and domain that it does not plan to use. Also, the peripheral central resource controller (PCR) has control registers to enable / disable the peripheral clock (VCLK) for each peripheral select. This offers the application a large number of choices for enabling / disabling clock sources, or clock domains, or clocks to specific peripherals.

This section describes three particular low-power modes and their typical characteristics. They are not the only low-power modes configurable by the application, as just described.

**Table 2-11. Typical Low-Power Modes**

| Mode Name | Active Clock Source(s) | Active Clock Domain(s) | Wake Up Options                                        | Suggested Wake Up Clock Source(s) | Wake Up Time(wake up detected -to- CPU code execution start)                                                                                                                           |
|-----------|------------------------|------------------------|--------------------------------------------------------|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Doze      | Main oscillator        | RTICK                  | RTI interrupt, GIO interrupt, CAN message, SCI message | Main oscillator                   | Flash pump sleep -> standby transition time<br>+<br>Flash bank sleep -> standby transition time<br>+<br>Flash bank standby -> active transition time                                   |
| Snooze    | LF LPO                 | RTICK                  | RTI interrupt, GIO interrupt, CAN message, SCI message | HF LPO                            | HF LPO warm start-up time<br>+<br>Flash pump sleep -> standby transition time<br>+<br>Flash bank sleep -> standby transition time<br>+<br>Flash bank standby -> active transition time |
| Sleep     | None                   | None                   | GIO interrupt, CAN message, SCI message                | HF LPO                            | HF LPO warm start-up time<br>+<br>Flash pump sleep -> standby transition time<br>+<br>Flash bank sleep -> standby transition time<br>+<br>Flash bank standby -> active transition time |

### 2.4.3.1 Typical Software Sequence to Enter a Low-Power Mode

1. Program the flash banks and flash pump fall-back modes to be “sleep”.  
The flash pump transitions from active to sleep mode only after all the flash banks have switched from active to sleep mode. The flash banks start switching from active to sleep mode only after the banks are not accessed for at least a duration defined by the Active Grace Period (AGP) parameter configured for the banks. See [Chapter 5](#) for more details.
2. Disable the clock sources that are not required to be kept active.  
A clock source does not get disabled until all clock domains using that clock source are disabled first, or are configured to use an alternate clock source.
3. Disable the clock domains that are not required to be kept active.  
A clock domain does not get disabled until all modules using that clock domain “give their permission” for that clock domain to be turned off.
4. Idle the Cortex-R4F core.  
The ARM Cortex-R4F CPU has internal power management logic, and requires a dedicated instruction to be used in order to enter a low power mode. This is the Wait For Interrupt (WFI) instruction. When a WFI instruction is executed, the Cortex-R4F core flushes its pipeline, flushes all write buffers, and completes all pending bus transactions. At this time the core indicates to the system that the clock to the core can be stopped. This indication is used by the Global Clock Module (GCM) to turn off the CPU clock domain (GCLK) if the CDDIS register bit 0 is set.

### 2.4.3.2 Special Considerations for Entry to Low Power Modes

Some bus master modules – High-End Timer Transfer Units (HTUx), FlexRay Transfer Unit (FTU), and Parameter Overlay Module (POM), can have ongoing transactions when the application wants to enter a low power mode to turn off the clocks to those modules. This is not recommended as it could leave the device in an unpredictable state. Refer to the individual module user guides for more information about the sequence to be followed to safely enter a low-power mode.

### 2.4.3.3 Selecting Clock Source Upon Wake Up

The domains for CPU clock (GCLK), the system clock (HCLK) and the peripheral clock (VCLKx) use the same clock source selected via the GHVSRC field of the GHVSRC register. The GHVSRC register also allows the application to choose the clock source after wake up via the GHVWAKE field.

When a wake up condition is detected, if the selected wake up clock source is not already active, the global clock module (GCM) will enable this selected clock source, wait for it to become valid, and then use it for the GCLK, HCLK and VCLKx domains. The other clock domains VCLKAx and RTICLK retain the configuration for their clock source selection registers – VCLKASRC, VCLKACON1 and RCLKSRC.

## 2.4.4 Clock Test Mode

The TMS570LS12x/11x microcontrollers support a test mode which allows a user to bring out several different clock sources and clock domains on to the ECLK terminal. This is very useful information for debug purposes. Each clock source also has a corresponding clock source valid status flag in the Clock Source Valid Status (CSVSTAT) register. The clock source valid status flags can also be brought out on to the NHET1[12] terminal in this clock test mode.

The clock test mode is controlled by the CLKTEST register ([Section 2.5.1.32](#)) in the system module register frame.

The clock test mode is enabled by writing 0x5 to the CLK\_TEST\_EN field.

The signal to be brought out on to the ECLK terminal is defined by the SEL\_ECP\_PIN field and the signal to be brought out on to the NHET1[12] terminal is defined by the SEL\_GIO\_PIN field.

The choices for these selections are defined in [Table 2-12](#).

**Table 2-12. Clock Test Mode Options**

| SEL_ECP_PIN | Signal on ECLK                 | SEL_GIO_PIN | Signal on NHET1[12]     |
|-------------|--------------------------------|-------------|-------------------------|
| 0000        | Oscillator                     | 0000        | Oscillator Valid status |

## 2.4.5 Safety Considerations for Clocks

The TMS570LS12x/11x microcontrollers are targeted for use in several safety-critical applications. The following sections describe the internal or external monitoring mechanisms that detect and signal clock source failures.

### 2.4.5.1 Oscillator Monitor

The oscillator clock frequency is monitored by a dedicated circuitry called CLKDET using the HF LPO as the reference clock. The CLKDET flags an oscillator fail condition whenever the OSCIN frequency falls outside of a range which is defined by the HF LPO frequency.

The valid OSCIN range is defined as a minimum of  $f_{(\text{HF LPO})} / 4$  to a maximum of  $f_{(\text{HF LPO})} \times 4$ .

The untrimmed HF LPO frequency on this device can range from 5.5MHz to 19.5MHz. This results in a valid OSCIN frequency range depicted in [Figure 2-4](#).

The application can select the device response to an oscillator fail indication. See [Chapter 10](#) for more details on the oscillator monitoring and the system response choices.

**Figure 2-4. LPO and Clock Detection, Untrimmed HF LPO**

### 2.4.5.2 PLL Slip Detector

Both the PLL macros implemented on the microcontrollers have an embedded slip detection circuit. A PLL slip is detected by the slip detector under the following conditions:

1. Reference cycle slip, RFSLIP — the output clock is running *too fast* relative to the reference clock
2. Feedback cycle slip, FBSLIP — the output clock is running *too slow* relative to the reference clock

The device also includes optional filters that can be enabled before a slip indication from the PLL is actually logged in the system module Global Status Register (GLBSTAT). Also, once a PLL slip condition is logged in the system module global status register, the application can choose the device's response to the slip indication. Refer to the Oscillator and PLL chapter for more details on PLL slip and the system response choices.

### 2.4.5.3 External Clock Monitor

The microcontrollers support a terminal called ECLK – External Clock, which is used to output a slow frequency which is divided down from the device system clock frequency. An external circuit can monitor the ECLK frequency in order to check that the device is operating at the correct frequency.

The frequency of the signal output on the ECLK pin can be divided down by 1 to 65536 from the peripheral clock (VCLK) frequency using the External Clock Prescaler Control Register (ECPCNTL). The actual clock output on ECLK is enabled by setting the ECP CLK FUN bit of the SYSPC1 control register.

### 2.4.5.4 Dual-Clock Comparators

The microcontrollers include two instances of the dual-clock comparator module. This module includes two down counters which independently count from two separate seed values at the rate of two independent clock frequencies. One of the clock inputs is a reference clock input, selectable between the main oscillator or the HF LPO in functional mode. The second clock input is selectable from among a set of defined signals as described in [Section 2.4.5.4.1](#) and [Section 2.4.5.4.2](#). This mechanism can be used to use a known-good clock to measure the frequency of another clock.

#### 2.4.5.4.1 DCC1

**Table 2-13. DCC1 Counter 0 Clock Inputs**

| Clock Source [3-0] | Clock / Signal Name |
|--------------------|---------------------|
| others             | oscillator (OSCIN)  |
| 0x5                | HF LPO              |
| 0xA                | test clock (TCK)    |

**Table 2-14. DCC1 Counter 1 Clock / Signal Inputs**

| Key [3-0] | Clock Source [3-0] | Clock / Signal Name      |
|-----------|--------------------|--------------------------|
| 0xA       | 0x0                | PLL1 free-running output |
|           | 0x1                | PLL2 free-running output |
|           | 0x2                | LF LPO                   |
|           | 0x3                | HF LPO                   |
|           | 0x4                | Reserved                 |
|           | 0x5                | EXTCLKIN1                |
|           | 0x6                | EXTCLKIN2                |
|           | 0x7                | Reserved                 |
|           | 0x8-0xF            | VCLK                     |
| others    | any value          | NHET1[31]                |

As can be seen, the main oscillator (OSCIN) can be used for counter 0 as a “known-good” reference clock. The clock for counter 1 can be selected from among 8 options. See [Chapter 11](#) for more details on the DCC usage.

#### 2.4.5.4.2 DCC2

**Table 2-15. DCC2 Counter 0 Clock Inputs**

| Clock Source [3-0] | Clock / Signal Name |
|--------------------|---------------------|
| others             | oscillator (OSCIN)  |
| 0xA                | test clock (TCK)    |

**Table 2-16. DCC2 Counter 1 Clock / Signal Inputs**

| Key [3-0] | Clock Source [3-0] | Clock / Signal Name |
|-----------|--------------------|---------------------|
| 0xA       | 0x0-0x7            | Reserved            |
|           | 0x8-0xF            | VCLK                |
| others    | any value          | NHET2[0]            |

As can be seen, the main oscillator (OSCIN) can be used for counter 0 as a “known-good” reference clock. The clock for counter 1 can be selected from among 2 options. See [Chapter 11](#) for more details on the DCC usage.

## 2.5 System and Peripheral Control Registers

The following sections describe the system and peripheral control registers of the TMS570LS12x/11x microcontroller.

### 2.5.1 Primary System Control Registers (SYS)

This section describes the SYSTEM registers. These registers are broken up into two separate frames. The start address of the primary system module frame is FFFF FF00h and the end address is FFFF FFFFh. The start address of the secondary system module frame is FFFF E100h and the end address is FFFF E1FFh. The registers support 32-, 16-, and 8-bit writes. The offset is relative to the system module frame start address.

Table 2-17 contains a list of the primary system control registers.

**Table 2-17. Primary System Control Registers**

| Offset  | Acronym     | Register Description                                   | Section                          |
|---------|-------------|--------------------------------------------------------|----------------------------------|

### 2.5.1.1 SYS Pin Control Register 1 (SYSPC1)

The SYSPC1 register, shown in [Figure 2-5](#) and described in [Table 2-18](#), controls the function of the ECLK pin.

**Figure 2-5. SYS Pin Control Register 1 (SYSPC1) [offset = 00]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 2-18. SYS Pin Control Register 1 (SYSPC1) Field Descriptions**

| Bit  | Field     | Value  | Description                                                                                                                                                                                                                                                          |
|------|-----------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-1 | Reserved  | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                               |
| 0    | ECPCLKFUN | 0<br>1 | ECLK function. This bit changes the function of the ECLK pin.<br>ECLK is in GIO mode.<br>ECLK is in functional mode as a clock output.<br><b>Note: Proper ECLK duty cycle is not guaranteed until 1 ECLK cycle has elapsed after switching into functional mode.</b> |

### 2.5.1.2 SYS Pin Control Register 2 (SYSPC2)

The SYSPC2 register, shown in [Figure 2-6](#) and described in [Table 2-19](#), controls whether the pin is an input or an output when in GIO mode.

**Figure 2-6. SYS Pin Control Register 2 (SYSPC2) [offset = 04h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 2-19. SYS Pin Control Register 2 (SYSPC2) Field Descriptions**

| Bit  | Field     | Value  | Description                                                                                                                                                                                                                                                                                                                                                                            |
|------|-----------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-1 | Reserved  | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                 |
| 0    | ECPCLKDIR | 0<br>1 | ECLK data direction. This bit controls the direction of the ECLK pin when it is configured to be in GIO mode only.<br>The ECLK pin is an input.<br><b>Note: If the pin direction is set as an input, the output buffer is tristated.</b><br>The ECLK pin is an output.<br><b>Note: The ECLK pin is placed into GIO mode by clearing the ECPCLKFUN bit to 0 in the SYSPC1 register.</b> |

### 2.5.1.3 SYS Pin Control Register 3 (SYSPC3)

The SYSPC3 register, shown in [Figure 2-7](#) and described in [Table 2-20](#), displays the logic state of the ECLK pin when it is in GIO mode.

**Figure 2-7. SYS Pin Control Register 3 (SYSPC3) [offset = 08h]**

**NOTE:** A list of the available clock sources is shown in [Table 2-28](#).

### 2.5.1.13 Clock Domain Disable Register (CDDIS)

The CDDIS register, shown in [Figure 2-17](#) and described in [Table 2-31](#), controls the state of the clock domains.

**NOTE:** All the clock domains are enabled on wakeup.

The application should guarantee that when HCLK and VCLK\_sys are turned off through the HCLKOFF bit, the GCLK domain is also turned off.

**Figure 2-17. Clock Domain Disable Register (CDDIS) [offset = 3Ch]**

### 2.5.1.14 Clock Domain Disable Set Register (CDDISSET)

This CDDISSET register, shown in [Figure 2-18](#) and described in [Table 2-32](#), sets clock domains to the disabled state.

**Figure 2-18. Clock Domain Disable Set Register (CDDISSET) [offset = 40h]**

| 7-4   | Reserved | 0     | Read returns 0. Writes have no effect.                          |
| 3-0   | VCLKA1S  | 0     | Peripheral asynchronous clock1 source.                          |
|       |          | 0     | Clock source0 is the source for peripheral asynchronous clock1. |
|       |          | 1h    | Clock source1 is the source for peripheral asynchronous clock1. |
|       |          | 2h    | Clock source2 is the source for peripheral asynchronous clock1. |
|       |          | 3h    | Clock source3 is the source for peripheral asynchronous clock1. |
|       |          | 4h    | Clock source4 is the source for peripheral asynchronous clock1. |
|       |          | 5h    | Clock source5 is the source for peripheral asynchronous clock1. |
|       |          | 6h    | Clock source6 is the source for peripheral asynchronous clock1. |
|       |          | 7h    | Clock source7 is the source for peripheral asynchronous clock1. |
|       |          | 8h-Fh | VCLK is the source for peripheral asynchronous clock1.          |

**NOTE:** Non implemented clock sources should not be enabled or used. A list of the available clock sources is shown in [Table 2-28](#).

### 2.5.1.18 RTI Clock Source Register (RCLKSRC)

The RCLKSRC register, shown in [Figure 2-22](#) and described in [Table 2-36](#), controls the RTI (Real Time Interrupt) clock source selection.

**NOTE: Important constraint when the RTI clock source is not VCLK**

If the RTIx clock source is chosen to be anything other than the default VCLK, then the RTI clock needs to be at least three times slower than the VCLK. This can be achieved by configuring the RTIxCLK divider in this register. This divider is internally bypassed when the RTIx clock source is VCLK.

**Figure 2-22. RTI Clock Source Register (RCLKSRC) [offset = 50h]**

This value will give maximum protection from a bit flip inducing event that would inadvertently enable the controller.</b> |

### 2.5.1.21 Memory Hardware Initialization Global Control Register (MINITGCR)

The MINITGCR register, shown in [Figure 2-25](#) and described in [Table 2-39](#), enables automatic hardware memory initialization.

**Figure 2-25. Memory Hardware Initialization Global Control Register (MINITGCR) [offset = 5Ch]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 2-39. Memory Hardware Initialization Global Control Register (MINITGCR) Field Descriptions**

| Bit  | Field     | Value                           | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|------|-----------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | Reserved  | 0                               | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                        |

### 2.5.1.22 MBIST Controller/ Memory Initialization Enable Register (MSINENA)

The MSINENA register, shown in [Figure 2-26](#) and described in [Table 2-40](#), enables PBIST controllers for memory self test and the memory modules initialized during automatic hardware memory initialization.

**Figure 2-26. MBIST Controller/Memory Initialization Enable Register (MSINENA) [offset = 60h]**

|    |        |    |
|----|--------|----|
| 31 | MSIENA | 16 |
|    | R/WP-0 |    |
| 15 | MSIENA | 0  |
|    | R/WP-0 |    |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 2-40. MBIST Controller/Memory Initialization Enable Register (MSINENA) Field Descriptions**

| Bit  | Field  | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------|--------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | MSIENA | 0     | <p>PBIST controller and memory initialization enable register. In memory self-test mode, all the corresponding bits of the memories to be tested should be set before enabling the global memory self-test controller key (MSTGENA) in the MSTGCR register (offset 58h). The reason for this is that MSTGENA, in addition to being the global enable for all individual PBIST controllers, is the source for the reset generation to all the PBIST controller state machines. Disabling the MSTGENA or MINITGENA key (by writing from Ah to any other value) will reset all the MSIENA[31-0] bits to their default values.</p> <p>In memory self-test mode (MSTGENA = Ah):<br/>PBIST controller [31-0] is disabled.</p> <p>In memory Initialization mode (MINITGENA = Ah):<br/>Memory module [31-0] auto hardware initialization is disabled.</p> |
|      |        | 1     | <p>In memory self-test mode (MSTGENA = 5h):<br/>PBIST controller [31-0] is enabled.</p> <p>In memory Initialization mode (MINITGENA = 5h):<br/>Memory module [31-0] auto hardware initialization is enabled.</p> <p><b>Note: Software should ensure that both the memory self-test global enable key (MSTGENA) and the memory hardware initialization global key (MINITGENA) are not enabled at the same time.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                            |

### 2.5.1.23 Memory Self-Test Fail Status Register (MSTFAIL)

The MSTFAIL register, shown in [Figure 2-27](#) and described in [Table 2-41](#), shows the fail status of the memory self-tests.

**Figure 2-27. Memory Self-Test Fail Status Register (MSTFAIL) [offset = 64h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 2-41. Memory Self-Test Fail Status Register (MSTFAIL) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                                                                                                                                          |
|------|-------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | MSTF  | 0     | Memory self-test fail status bit.<br><i>Read:</i> PBIST controller [31-0] run did not fail.<br><i>Write:</i> A write of 0 has no effect.                                                                                                             |
|      |       | 1     | <i>Read:</i> PBIST controller [31-0] run failed.<br><i>Write:</i> The bit is cleared to 0.<br><b>Note:</b> Disabling the MSTGENA key (by writing from Ah to any other value) will reset all the individual fail status bits to their default values. |

### 2.5.1.24 MSTC Global Status Register (MSTCGSTAT)

The MSTCGSTAT register, shown in [Figure 2-28](#) and described in [Table 2-42](#), shows the status of the memory hardware initialization and the memory self-test.

**Figure 2-28. MSTC Global Status Register (MSTCGSTAT) [offset = 68h]**

LEGEND: R/W = Read/Write; R = Read only; C = Clear; WP = Write in privileged mode only; -n = value after reset

**Table 2-42. MSTC Global Status Register (MSTCGSTAT) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-9 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                              |
| 8    | MINIDONE | 0     | Memory hardware initialization complete status.<br><b>Note: Disabling the MINITGENA key (By writing from Ah to any other value) will clear the MINIDONE status bit to 0.</b><br><b>Note: Individual memory initialization status is shown in the MINISTAT register.</b><br><i>Read:</i> Memory hardware initialization is not complete for all memory.<br><i>Write:</i> A write of 0 has no effect. |
|      |          | 1     | <i>Read:</i> Hardware initialization of all memory is completed.<br><i>Write:</i> The bit is cleared to 0.                                                                                                                                                                                                                                                                                          |
| 7-1  | Reserved | 0     | Read returns 0. ### 2.5.1.25 Memory Hardware Initialization Status Register (MINISTAT)

The MINISTAT register, shown in [Figure 2-29](#) and described in [Table 2-43](#), indicates the status of hardware memory initialization.

**Figure 2-29. Memory Hardware Initialization Status Register (MINISTAT) [offset = 6Ch]**

|      |        | 1     | <i>Read:</i> Memory module[31-0] hardware initialization is completed.<br><i>Write:</i> The bit is cleared to 0.<br><b>Note:</b> Disabling the MINITGENA key (by writing from Ah to any other value) will reset all the individual status bits to 0. |

### 2.5.1.26 PLL Control Register 1 (PLLCTL1)

The PLLCTL1 register, shown in [Figure 2-30](#) and described in [Table 2-44](#), controls the output frequency of PLL1 (Clock Source 1 - FMzPLL). It also controls the behavior of the device if a PLL slip or oscillator failure is detected.

**Figure 2-30. PLL Control Register 1 (PLLCTL1) [offset = 70h]**

|            |           |         |    |    |        |      |           |    |

### 2.5.1.27 PLL Control Register 2 (PLLCTL2)

The PLLCTL2 register, shown in [Figure 2-31](#) and described in [Table 2-45](#), controls the modulation characteristics and the output divider of the PLL.

**Figure 2-31. PLL Control Register 2 (PLLCTL2) [offset = 74h]**

### 2.5.1.28 SYS Pin Control Register 10 (SYSPC10)

The SYSPC10 register, shown in [Figure 2-32](#) and described in [Table 2-46](#), controls the function of the ECPCLK slew mode.

**Figure 2-32. SYS Pin Control Register 10 (SYSPC10) [offset = 78h]**

|    |          |             |
|----|----------|-------------|

|    | R-0      |             |
| 15 | Reserved | 1 0         |
|    | R-0      | ECPCLK_SLEW |
|    |          | R/W-0       |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 2-46. SYS Pin Control Register 10 (SYSPC10) Field Descriptions**

| Bit  | Field       | Value | Description                                                                                                                                        |
|------|-------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-1 | Reserved    | 0     | Read returns 0. Writes have no effect.                                                                                                             |
| 0    | ECPCLK_SLEW | 0     | ECPClk slew control. This bit controls between the fast or slow slew mode.<br>Fast mode is enabled; the normal output buffer is used for this pin. |
|      |             | 1     | Slow mode is enabled; slew rate control is used for this pin.                                                                                      |

### 2.5.1.29 Die Identification Register Lower Word (DIEIDL)

The DIEIDL register, shown in [Figure 2-33](#) and described in [Table 2-47](#), contains information about the die lot number, wafer number, and X, Y wafer coordinates.

**Figure 2-33. Die Identification Register, Lower Word (DIEIDL) [offset = 7Ch]**

LEGEND: R = Read only; -n = value after reset; -D = device specific

**Table 2-47. Die Identification Register, Lower Word (DIEIDL) Field Descriptions**

| Bit   | Field                 | Description                                                              |
|-------|-----------------------|--------------------------------------------------------------------------|
| 31-22 | LOT # (Lower 10 Bits) | These read only bits contain the lower 10 bits of the device lot number. |
| 21-16 | WAFER #               | These read only bits contain the wafer number of the device.             |
| 15-8  | Y WAFER COORDINATE    | These read only bits contain the Y wafer coordinate of the device        |
| 7-0   | X WAFER COORDINATE    | These read only bits contain the X wafer coordinate of the device        |

**NOTE: Die Identification Information**

The die identification information will vary from unit to unit. This information is programmed by TI as part of the initial device test procedure.

### 2.5.1.30 Die Identification Register Upper Word (DIEIDH)

The DIEIDH register, shown in [Figure 2-34](#) and described in [Table 2-48](#), contains information about the die lot number.

**Figure 2-34. Die Identification Register, Upper Word (DIEIDH) [offset = 80h]**

LEGEND: R/W = Read/Write; R = Read only; D = Value is device dependent; -n = value after reset

**Table 2-48. Die Identification Register, Upper Word (DIEIDH) Field Descriptions**

| Bit   | Field                 | Value | Description                                                                  |
|-------|-----------------------|-------|------------------------------------------------------------------------------|
| 31-14 | Reserved              | 0     | Read returns 0. Writes have no effect.                                       |
| 13-0  | LOT # (Upper 14 Bits) |       | This read-only register contains the upper 14 bits of the device lot number. |

**NOTE: Die Identification Information**

The die identification information will vary from unit to unit. This information is programmed by TI as part of the initial device test procedure.

### 2.5.1.31 LPO/Clock Monitor Control Register (LPOMONCTL)

The LPOMONCTL register, shown in [Figure 2-35](#) and described in [Table 2-49](#), controls the Low Frequency (Clock Source 4) and High Frequency (Clock Source 5) Low Power Oscillator's trim values.

**Figure 2-35. LPO/Clock Monitor Control Register (LPOMONCTL) [offset = 088h]**

|          |  |    |          |             |  |          |  |          |  |                 |          |   |  |   |  |

| 4-0 | LFTRIM |       | <p>Low frequency oscillator trim value. This four-bit value is used to center the LF oscillator's frequency.</p> <p><b>Caution: This value should only be changed when the LF oscillator is not the source for a clock domain, otherwise a system failure could result.</b></p> <p>The values below are the ratio: <math>f / f_0</math> in the F021 process.</p> |

### 2.5.1.32 Clock Test Register (CLKTEST)

The CLKTEST register, shown in [Figure 2-36](#) and described in [Table 2-50](#), controls the clock signal that is supplied to the ECLK pin for test and debug purposes.

**NOTE: Clock Test Register Usage**

This register should only be used for test and debug purposes.

**Figure 2-36. Clock Test Register (CLKTEST) [offset = 8Ch]**

|-------|--------------------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | EMIF_FUNC                | 0              | Enable EMIF functions to be output. EMIF_ADDR[0], EMIF_ADDR[1], EMIF_ADDR[6], EMIF_ADDR[7], EMIF_ADDR[8], EMIF_BA[1], EMIF_nCS[0], and EMIF_nCS[3] are multiplexed with N2HET2 signals. By default, these terminals are tri-stated and pulled down. Any application that requires the EMIF functionality must set the EMIF_FUNC bit. This allows these 8 EMIF module outputs to be driven on to the assigned balls.                                                                                                                                                                                               |
| 30-26 | Reserved                 | 0              | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 25-20 | PLL1_FBSLIP_FILTER_COUNT | 0-3Fh          | FBSLIP down counter programmed value.<br><br>Configures the system response when a FBSLIP is indicated by the PLL macro. When PLL1_RFSLIP_FILTER_KEY is not 1010, the down counter counts from the programmed value on every LPO high frequency clock once PLL macro indicates FBSLIP. When the count reaches zero, if the synchronized FBSLIP signal is still high, an FBSLIP condition is indicated to the system module and is captured in the global status register. When the FBSLIP signal from the PLL macro is de-asserted before the count reaches 0, the counter is reloaded with the programmed value. |
| 19-16 | PLL1_RFSLIP_FILTER_KEY   | 5h<br>Ah<br>Fh | Configures the system response when a FBSLIP is indicated by the PLL macro.<br><br>5h The FBSLIP filter is bypassed and the FBSLIP indicated by the PLL macro is captured in the system module global status register.<br><br>Ah The FBSLIP filter is enabled and the one-stage synchronization circuit is used.<br><br>Fh The FBSLIP filter is enabled and the two-stage synchronization circuit is used.                                                                                                                                                                                                        |

**Table 2-53. General Purpose Register (GPREG1) Field Descriptions (continued)**

| Bit  | Field                      | Value    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### 2.5.1.36 Imprecise Fault Status Register (IMPFASTS)

The IMPFASTS register, shown in [Figure 2-40](#) and described in [Table 2-54](#), displays information about imprecise aborts that have occurred.

**Figure 2-40. Imprecise Fault Status Register (IMPFASTS) [offset = A8h]**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                      |
|-------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                           |
| 15-8  | SSKEY1   | 0-FFh | System software interrupt request key. A 075h written to these bits initiates IRQ/FIQ interrupts. Data in this field is always read as 0. The SSKEY1 field can be written into only if the write data matches the key (75h). The SSDATA1 field can only be written into if the write data into this field, the SSKEY1 field, matches the key (75h).              |
| 7-0   | SSDATA1  | 0-FFh | System software interrupt data. These bits contain user read/write register bits. They may be used by the application software as different entry points for the interrupt routine. The SSDATA1 field cannot be written into unless the write data into the SSKEY1 field matches the key (75h); therefore, byte writes cannot be performed on the SSDATA1 field. |

**NOTE:** This register is mirrored at offset FCh for compatibility reasons.

### 2.5.1.39 System Software Interrupt Request 2 Register (SSIR2)

The SSIR2 register, shown in [Figure 2-43](#) and described in [Table 2-57](#), is used for software interrupt generation.

**Figure 2-43. System Software Interrupt Request 2 Register (SSIR2) [offset = B4h]**

**Table 2-59. System Software Interrupt Request 4 Register (SSIR4) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                      |
|-------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                           |
| 15-8  | SSKEY4   | 0-FFh | System software interrupt2 request key. A A2h written to these bits initiates IRQ/FIQ interrupts. Data in this field is always read as 0. The SSKEY4 field can be written into only if the write data matches the key (A2h). The SSDATA4 field can only be written into if the write data into this field, the SSKEY4 field, matches the key (A2h).              |
| 7-0   | SSDATA4  | 0-FFh | System software interrupt data. These bits contain user read/write register bits. They may be used by the application software as different entry points for the interrupt routine. The SSDATA4 field cannot be written into unless the write data into the SSKEY4 field matches the key (A2h); therefore, byte writes cannot be performed on the SSDATA4 field. |

### 2.5.1.42 RAM Control Register (RAMGCR)

The RAMGCR register, shown in Figure 2-46 and described in Table 2-60, is used to configure eSRAM data and address wait states.

**NOTE:** The RAM\_DFT\_EN bits are for TI internal use only.

The contents of the RAM\_DFT\_EN field should not be changed.

**Figure 2-46. RAM Control Register (RAMGCR) [offset = C0h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 2-60. RAM Control Register (RAMGCR) Field Descriptions**

| Bit   | Field      | Value        | Description                                                                                                                                                                                                                                                                                                                                                                    |
|-------|------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-20 | Reserved   | 0            | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                         |

### 2.5.1.43 Bus Matrix Module Control Register 1 (BMMCR1)

The BMMCR1 register, shown in [Figure 2-47](#) and described in [Table 2-61](#), allows RAM and Program (Flash) memory addresses to be swapped.

**Figure 2-47. Bus Matrix Module Control Register 1 (BMMCR) [offset = C4h]**

### 2.5.1.44 CPU Reset Control Register (CPURSTCR)

The CPURSTCR register shown in [Figure 2-48](#) and described in [Table 2-62](#), allows the memory protection mode to be configured. It also allows a reset to the Cortex R4 CPU to be generated.

**Figure 2-48. CPU Reset Control Register (CPURSTCR) [offset = CCh]**

| 0    | CPU RESET |       | CPU Reset.<br>Only the CPU is reset whenever this bit is toggled. There is no system reset. |

### 2.5.1.45 Clock Control Register (CLKCNTL)

The CLKCNTL register, shown in [Figure 2-49](#) and described in [Table 2-63](#), controls peripheral reset and the peripheral clock divide ratios.

**NOTE: VCLK and VCLK2 clock ratio restrictions.**

VCLK2 must always be greater than or equal to VCLK. In addition, the VCLK and VCLK2 clock ratios must not be changed simultaneously. The application must configure the VCLK2 ratio, read back the contents of the CLKCNTL register, and then configure the VCLK ratio.

**Figure 2-49. Clock Control Register (CLKCNTL) [offset = D0h]**

|          |    |         |        |          |     |         |    |

### 2.5.1.46 ECP Control Register (ECPCNTL)

The ECP register, shown in [Figure 2-50](#) and described in [Table 2-64](#), configures the ECLK pin in functional mode.

**NOTE: ECLK Functional mode configuration.**

The ECLK pin must be placed into Functional mode by setting the ECPCLKFUN bit to 1 in the SYSPC1 register before a clock source will be visible on the ECLK pin.

**Figure 2-50. ECP Control Register (ECPCNTL) [offset = D4h]**

|-------|------------|--------|----------------------------------------------------------------------------------------|
| 31-16 | Reserved   | 0      | Read returns 0. Writes have no effect.                                                 |
| 15-14 | RESET[1-0] |        | Software reset bits. Setting RESET1 or clearing RESET0 causes a system software reset. |
|       |            | 1h     | No reset will occur.                                                                   |
|       |            | 1x, x0 | A global system reset will occur.                                                      |
| 13-0  | Reserved   | 0      | Read returns 0. Writes have no effect.                                                 |

### 2.5.1.49 System Exception Status Register (SYSESR)

The SYSESR register, shown in Figure 2-53 and described in Table 2-67, shows the source for different resets encountered. Previous reset source status bits are not automatically cleared if new resets occur. All bits in this register can be cleared by writing a '1' to the bit.

**Figure 2-53. System Exception Status Register (SYSESR) [offset = E4h]**

|      |             | 1h     | <i>Read:</i> Controller times out because there is no last row sent from the FuseROM.                                                                                                                                                                                                                                                                          |
|      |             | 2h     | <i>Read:</i> The autoloading machine was started, either through the SYS_INITZ signal from the system or the JTAG data register. In either case, the autoloading machine did not find enough FuseROM data to fill the scan chain.                                                                                                                              |
|      |             | 3h     | <i>Read:</i> The autoloading machine was started, either through the SYS_INITZ signal from the system or the JTAG data register. In either case, the autoloading machine starts the scan chain with a signature it expects to see after the scan chain is full. The autoloading machine was able to fill the scan chain, but the wrong signature was returned. |
|      |             | 4h     | <i>Read:</i> The autoloading machine was started, either through the SYS_INITZ signal from the system or the JTAG data register. In either case, the autoloading machine was not able or not allowed to complete its operation.                                                                                                                                |
|      |             | Others | <i>Read:</i> Reserved.                                                                                                                                                                                                                                                                                                                                         |
|      |             | 1Fh    | <i>Write:</i> These bits are cleared to 0.                                                                                                                                                                                                                                                                                                                     |

### 2.5.1.51 Global Status Register (GLBSTAT)

The GLBSTAT register, shown in [Figure 2-55](#) and described in [Table 2-69](#), indicates the FMzPLL (PLL1) slip status and the oscillator fail status.

**NOTE: PLL and OSC fail behavior**

The device behavior after a PLL slip or an oscillator failure is configured in the PLLCTL1 register.

**Figure 2-55. Global Status Register (GLBSTAT) [offset = ECh]**

LEGEND: R/W = Read/Write; R = Read only; C = Clear; -n = value after reset

**Table 2-69. Global Status Register (GLBSTAT) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                       |

| 7-1   | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                            |
| 0     | OSCFAIL  | 0     | Oscillator fail flag bit.<br><i>Read:</i> No oscillator failure has been detected.<br><i>Write:</i> The bit is unchanged.         |
|       |          | 1     | <i>Read:</i> An oscillator failure has been detected.<br><i>Write:</i> The bit is cleared to 0.                                   |

### 2.5.1.52 Device Identification Register (DEVID)

The DEVID is a read-only register. It contains device-specific information that is hard-coded during device manufacture. For the initial silicon version, the device identification code value is 802A AD05h. This register is shown in [Figure 2-56](#) and described in [Table 2-70](#).

**Figure 2-56. Device Identification Register (DEVID) [offset = F0h]**

### 2.5.1.53 Software Interrupt Vector Register (SSIVEC)

The SSIVEC register, shown in [Figure 2-57](#) and described in [Table 2-71](#), contains information about software interrupts.

**Figure 2-57. Software Interrupt Vector Register (SSIVEC) [offset = F4h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 2-71. Software Interrupt Vector Register (SSIVEC) Field Descriptions**

| Bit   | Field    | Value                                                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### 2.5.1.54 System Software Interrupt Flag Register (SSIF)

The SSIF register, shown in [Figure 2-58](#) and described in [Table 2-72](#), contains software interrupt flag status information.

**Figure 2-58. System Software Interrupt Flag Register (SSIF) [offset = F8h]**

LEGEND: R/W = Read/Write; R = Read only; C = Clear; -n = value after reset

**Table 2-72. System Software Interrupt Flag Register (SSIF) Field Descriptions**

| Bit  | Field         | Value | Description                                                                                                                                                                                                                                                                                          |
|------|---------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | Reserved      | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                               |
| 3-0  | SSI_FLAG[4-1] |       | System software interrupt flag[4-1]. |      |               | 0     | <i>Read:</i> No IRQ/FIQ interrupt was generated since the bit was last cleared.<br><i>Write:</i> The bit is unchanged.                                                                                                                                                                               |
|      |               | 1     | <i>Read:</i> An IRQ/FIQ interrupt was generated.<br><i>Write:</i> The bit is cleared to 0.                                                                                                                                                                                                           |

## 2.5.2 Secondary System Control Registers (SYS2)

[Table 2-73](#) lists the secondary frame of system registers. The start address of the second system module frame is FFFF E100h and the end address is FFFF E1FFh. The registers support 32-, 16-, and 8-bit writes. The offset is relative to the system module frame start address.

**Table 2-73. Secondary System Control Registers**

| Offset  | Acronym    | Register Description                                   | Section                          |

### 2.5.2.1 PLL Control Register 3 (PLLCTL3)

The PLLCTL3 register is shown in [Figure 2-59](#) and described in [Table 2-74](#); controls the settings of PLL2 (Clock Source 6 - FPLL).

**Figure 2-59. PLL Control Register 3 (PLLCTL3) [offset = 00]**

**Table 2-77. Peripheral Asynchronous Clock Configuration 1 Register (VCLKACON1) Field Descriptions**  
**(continued)**

| Bit | Field   | Value | Description                                                     |
|-----|---------|-------|-----------------------------------------------------------------|
| 3-0 | VCLKA3S |       | Peripheral asynchronous clock3 source.                          |
|     |         | 0     | Clock source0 is the source for peripheral asynchronous clock3. |
|     |         | 1h    | Clock source1 is the source for peripheral asynchronous clock3. |
|     |         | 2h    | Clock source2 is the source for peripheral asynchronous clock3. |
|     |         | 3h    | Clock source3 is the source for peripheral asynchronous clock3. |
|     |         | 4h    | Clock source4 is the source for peripheral asynchronous clock3. |
|     |         | 5h    | Clock source5 is the source for peripheral asynchronous clock3. |
|     |         | 6h    | Clock source6 is the source for peripheral asynchronous clock3. |
|     |         | 7h    | Clock source7 is the source for peripheral asynchronous clock3. |
|     |         | 8h-Fh | VCLK is the source for peripheral asynchronous clock3.          |

**NOTE:** Nonimplemented clock sources should not be enabled or used. A list of the available clock sources is shown in [Table 2-9](#).

#### 2.5.2.5 Clock Slip Register (CLKSLIP)

This register is shown in [Figure 2-63](#) and described in [Table 2-78](#).

**Figure 2-63. Clock Slip Register (CLKSLIP) [offset = 70h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

### Table 2-78. Clock Slip Register (CLKSLIP) Field Descriptions

| Bit   | Field                  | Value  | Description                                                                                                                                                                                        |
|-------|------------------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-14 | Reserved               | 0      | Read returns 0. Writes have no effect.                                                                                                                                                             |
| 13-8  | PLL1_SLIP_FILTER_COUNT | 0      | Configure the count for the filtered PLL slip. Count is on 10M clock.<br>On reset, counter value is zero. Counter must be programmed to non-zero value and enabled for the filtering to be enabled |
|       |                        | 1h-3Fh | Counter programmed to a non-zero value                                                                                                                                                             |
| 7-4   | Reserved               | 0      | Read returns 0. Writes have no effect.                                                                                                                                                             |
| 3-0   | PLL1_SLIP_FILTER_KEY   |        | Enable the PLL filtering.                                                                                                                                                                          |
|       |                        | 5h     | On reset, the PLL filter is disabled and normal PLL slip passes through.                                                                                                                           |
|       |                        | Fh     | This is an unsupported value. User should avoid writing this value to this field.                                                                                                                  |
|       |                        | Others | Enable of filtered PLL slip. Recommended to program 1010 in these bit fields. Enable of PLL slip occurs when the KEY is programmed and a non-zero value is present in the COUNT field.             |

### 2.5.2.6 EFUSE Controller Control Register (EFC\_CTLREG)

This register is shown in [Figure 2-64](#) and described in [Table 2-79](#).

**Figure 2-64. EFUSE Controller Control Register (EFC\_CTLREG) [offset = ECh]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 2-79. EFUSE Controller Control Register (EFC\_CTLREG) Field Descriptions**

| Bit  | Field         | Value        | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|------|---------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | Reserved      | 0            | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                  |
| 3-0  | EFC_INSTR_WEN | Ah<br>Others | Enable user write of 4 EFUSE controller instructions.<br>SYS module generates the enable signal which will be tied to OCP_FROM_WRITE_DISABLE on efuse controller port<br>Writing of instructions (Program, ProgramCRA, RunAutoload, and LoadFuseScanchain) to EFC is allowed enabled.<br>Writing of instructions (Program, ProgramCRA, RunAutoload, and LoadFuseScanchain) in EFC registers is blocked. |

### 2.5.2.7 Die Identification Register Lower Word (DIEIDL\_REG0)

This register is shown in [Figure 2-65](#) and described in [Table 2-80](#).

**Figure 2-65. Die Identification Register, Lower Word (DIEIDL\_REG0) [offset = F0h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; -X = Value unchanged after reset

**Table 2-80. Die Identification Register, Lower Word (DIEIDL\_REG0) Field Descriptions**

| Bit  | Field        | Value        | Description                                                                       |
|------|--------------|--------------|-----------------------------------------------------------------------------------|
| 31-0 | DIEIDL(31-0) | 0-FFFF FFFFh | This read-only register contains the lower word (31:0) of the die ID information. |

### 2.5.2.8 Die Identification Register Upper Word (DIEIDH\_REG1)

This register is shown in [Figure 2-66](#) and described in [Table 2-81](#).

**Figure 2-66. Die Identification Register, Upper Word (DIEIDH\_REG1) [offset = F4h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; -X = Value unchanged after reset

**Table 2-81. Die Identification Register, Upper Word (DIEIDH\_REG1) Field Descriptions**

| Bit  | Field         | Value        | Description                                                                        |
|------|---------------|--------------|------------------------------------------------------------------------------------|
| 31-0 | DIEIDH(63-32) | 0-FFFF FFFFh | This read-only register contains the upper word (63:32) of the die ID information. |

### 2.5.2.9 Die Identification Register Lower Word (DIEIDL\_REG2)

This register is shown in [Figure 2-67](#) and described in [Table 2-82](#).

**Figure 2-67. Die Identification Register, Lower Word (DIEIDL\_REG2) [offset = F8h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; -X = Value unchanged after reset

**Table 2-82. Die Identification Register, Lower Word (DIEIDL\_REG2) Field Descriptions**

| Bit  | Field          | Value        | Description                                                                        |
|------|----------------|--------------|------------------------------------------------------------------------------------|
| 31-0 | DIEIDL2(95-64) | 0-FFFF FFFFh | This read-only register contains the lower word (95:64) of the die ID information. |

### 2.5.2.10 Die Identification Register Upper Word (DIEIDH\_REG3)

This register is shown in [Figure 2-68](#) and described in [Table 2-83](#).

**Figure 2-68. Die Identification Register, Upper Word (DIEIDH\_REG3) [offset = FCh]**

| Bit  | Field           | Value        | Description                                                                         |
|------|-----------------|--------------|-------------------------------------------------------------------------------------|
| 31-0 | DIEIDH2(127-96) | 0-FFFF FFFFh | This read-only register contains the upper word (127:97) of the die ID information. |

### 2.5.3 Peripheral Central Resource (PCR) Control Registers

This section describes the Peripheral Central Resource (PCR) control registers. The start address of the PCR register frame is FFFF E000h and the end address is FFFF E0FFh. [Table 2-84](#) summarizes the registers in the PCR, which are used to configure protection to the peripherals in PCS and PS regions. The following sections provide detailed information about these registers. Not all chip selects exist on this device.

**Table 2-84. Peripheral Central Resource Control Registers**

| Offset  | Acronym       | Register Description                          | Section                          |

### 2.5.3.1 Peripheral Memory Protection Set Register 0 (PMPROTSET0)

This register is shown in [Figure 2-69](#) and described in [Table 2-85](#).

**NOTE:** Only those bits that have a slave at the corresponding bit position are implemented. Writes to nonimplemented bits have no effect and reads are 0.

**Figure 2-69. Peripheral Memory Protection Set Register 0 (PMPROTSET0) [offset = 00]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 2-85. Peripheral Memory Protection Set Register 0 (PMPROTSET0) Field Descriptions**

| Bit  | Field            | Value | Description                                                                                                                                                                                                                          |
|------|------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | PCS[31-0]PROTSET | 0     | Peripheral memory frame protection set.<br><i>Read:</i> The peripheral memory frame can be written to and read from in both user and privileged modes.<br><i>Write:</i> The bit is unchanged.                                        |
|      |                  | 1     | <i>Read:</i> The peripheral memory frame can be written to only in privileged mode, but it can be read in both user and privileged modes.<br><i>Write:</i> The corresponding bit in PMPROTSET0 and PMPROTCLR0 registers is set to 1. |

### 2.5.3.2 Peripheral Memory Protection Set Register 1 (PMPROTSET1)

This register is shown in [Figure 2-70](#) and described in [Table 2-86](#).

**NOTE:** Only those bits that have a slave at the corresponding bit position are implemented. Writes to nonimplemented bits have no effect and reads are 0.

**Figure 2-70. Peripheral Memory Protection Set Register 1 (PMPROTSET1) [offset = 04h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

### Table 2-86. Peripheral Memory Protection Set Register 1 (PMPROTSET1) Field Descriptions

| Bit  | Field             | Value | Description                                                                                                                                                                                                                          |
|------|-------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | PCS[63-32]PROTSET | 0     | Peripheral memory frame protection set.<br><i>Read:</i> The peripheral memory frame can be written to and read from in both user and privileged modes.<br><i>Write:</i> The bit is unchanged.                                        |
|      |                   | 1     | <i>Read:</i> The peripheral memory frame can be written to only in privileged mode, but it can be read in both user and privileged modes.<br><i>Write:</i> The corresponding bit in PMPROTSET1 and PMPROTCLR1 registers is set to 1. |

### 2.5.3.3 Peripheral Memory Protection Clear Register 0 (PMPROTCLR0)

This register is shown in [Figure 2-71](#) and described in [Table 2-87](#).

**NOTE:** Only those bits that have a slave at the corresponding bit position are implemented. Writes to nonimplemented bits have no effect and reads are 0.

**Figure 2-71. Peripheral Memory Protection Clear Register 0 (PMPROTCLR0) [offset = 10h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 2-87. Peripheral Memory Protection Clear Register 0 (PMPROTCLR0) Field Descriptions**

| Bit  | Field            | Value | Description                                                                                                                                                                                                                              |
|------|------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | PCS[31-0]PROTCLR | 0     | Peripheral memory frame protection clear.<br><i>Read:</i> The peripheral memory frame can be written to and read from in both user and privileged modes.<br><i>Write:</i> The bit is unchanged.                                          |
|      |                  | 1     | <i>Read:</i> The peripheral memory frame can be written to only in privileged mode, but it can be read in both user and privileged modes.<br><i>Write:</i> The corresponding bit in PMPROTSET0 and PMPROTCLR0 registers is cleared to 0. |

### 2.5.3.4 Peripheral Memory Protection Clear Register 1 (PMPROTCLR1)

This register is shown in [Figure 2-72](#) and described in [Table 2-88](#).

**NOTE:** Only those bits that have a slave at the corresponding bit position are implemented. Writes to nonimplemented bits have no effect and reads are 0.

**Figure 2-72. Peripheral Memory Protection Clear Register 1 (PMPROTCLR1) [offset = 14h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 2-88. Peripheral Memory Protection Clear Register 1 (PMPROTCLR1) Field Descriptions**

| Bit  | Field             | Value | Description                                                                                                                                                                                                                              |
|------|-------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | PCS[63-32]PROTCLR | 0     | Peripheral memory frame protection clear.<br><i>Read:</i> The peripheral memory frame can be written to and read from in both user and privileged modes.<br><i>Write:</i> The bit is unchanged.                                          |
|      |                   | 1     | <i>Read:</i> The peripheral memory frame can be written to only in privileged mode, but it can be read in both user and privileged modes.<br><i>Write:</i> The corresponding bit in PMPROTSET1 and PMPROTCLR1 registers is cleared to 0. |

### 2.5.3.5 Peripheral Protection Set Register 0 (PPROTSET0)

There is one bit for each quadrant for PS0 to PS7.

The following are the ways in which quadrants are used within a PS frame-

- (a) The slave uses all the four quadrants  
Only the bit corresponding to the quadrant 0 of PSn is implemented. It protects the whole 1K-byte frame. The remaining three bits are not implemented.
- (b) The slave uses two quadrants  
Each quadrant has to be in one of these groups- (Quad 0 and Quad 1), or (Quad 2 and Quad 3).  
For the group Quad0/Quad1, the bit quadrant 0 protects both quadrants 0 and 1. The bit quadrant 1 is not implemented.  
For the group Quad2/Quad3, the bit quadrant 2 protects both quadrants 2 and 3. The bit quadrant 3 is not implemented.
- (c) The slave uses only one quadrant.  
In this case, the bit, as specified in [Table 2-89](#), protects the slave.

The above arrangement is true for all the peripheral select (PS0 to PS31), presented in [Section 2.5.3.6 - Section 2.5.3.12](#). This register holds bits for PS0 to PS7 and is shown in [Figure 2-73](#) and described in [Table 2-89](#).

**NOTE:** Writes to nonimplemented bits have no effect and reads are 0.

**Figure 2-73. Peripheral Protection Set Register 0 (PPROTSET0) [offset = 20h]**

### 2.5.3.9 Peripheral Protection Clear Register 0 (PPROTCLR0)

There is one bit for each quadrant for PS0 to PS7. The protection scheme is described in [Section 2.5.3.5](#). This register is shown in [Figure 2-77](#) and described in [Table 2-93](#).

**NOTE:** Only those bits that have a slave at the corresponding bit position are implemented. Writes to nonimplemented bits have no effect and reads are 0.

### 2.5.3.17 Peripheral Power-Down Set Register 0 (PSPWRDWNSET0)

There is one bit for each quadrant for PS0 to PS7. Each bit of this register corresponds to the bit at the same index in the corresponding PPROT register in that they relate to the same peripheral. These bits are used to power down/power up the clock to the corresponding peripheral.

For every bit implemented in the PPROT register, there is one bit in the PSnPWRDWN register, except when two peripherals (both in PS area) share buses. In that case, only one Power-Down bit is implemented, at the position corresponding to that peripheral whose quadrant comes first (the lower numbered).

The ways in which quadrants can be used within a frame are identical to what is described under PPROTSET0, [Section 2.5.3.5](#).

This arrangement is the same for bits of PS8 to PS31, presented in [Section 2.5.3.18](#) - [Section 2.5.3.24](#). This register holds bits for PS0 to PS7. This register is shown in [Figure 2-85](#) and described in [Table 2-101](#).

**NOTE:** Only those bits that have a slave at the corresponding bit position are implemented. Writes to nonimplemented bits have no effect and reads are 0.

**Figure 2-85. Peripheral Power-Down Set Register 0 (PSPWRDWNSET0) [offset = 80h]**

### 2.5.3.18 Peripheral Power-Down Set Register 1 (PSPWRDWNSET1)

There is one bit for each quadrant for PS8 to PS15. The protection scheme is described in [Section 2.5.3.17](#). This register is shown in [Figure 2-86](#) and described in [Table 2-102](#).

**NOTE:** Only those bits that have a slave at the corresponding bit position are implemented. Writes to nonimplemented bits have no effect and reads are 0.

## ***Power Management Module (PMM)***

---

---

This chapter describes the power management module (PMM).

| <b>Topic</b>                   | <b>Page</b> |
|--------------------------------|-------------|
| <b>3.1 Overview .....</b>      | <b>206</b>  |
| <b>3.2 Power Domains .....</b> | <b>208</b>  |
| <b>3.3 PMM Operation .....</b> | <b>209</b>  |
| <b>3.4 PMM Registers .....</b> | <b>211</b>  |

## 3.1 Overview

This microcontroller is part of the Hercules family of microcontrollers from Texas Instruments for safety-critical applications. Several functions are implemented on this microcontroller targeted towards varied applications. The core logic is divided into several domains that can be independently turned on or off based on the application's requirements. This allows an application to reduce the leakage current for a core domain that has modules that are not being used by the application.

This chapter describes the Power Management Module (PMM). The PMM provides memory-mapped registers that control the states of the supported power domains. The PMM includes interfaces to the Power Mode Controller (PMC) and the Power State Controller (PSCON). The PMC and PSCON control the power up/down sequence of each power domain.

### 3.1.1 Main Features of the Power Management Module (PMM)

The main features of the PMM implemented on the microcontroller are:

- Supports 5 logic power domains: PD1, PD2, PD3, PD4, and PD5
- Supports 2 memory-only power domains: RAM\_PD1, RAM\_PD2
- Manages the clocks for each power domain
- Manages the resets to each power domain
- Includes failsafe compare logic to continuously monitor the states of each power domain
- Supports diagnostic and self-test logic to validate failsafe compare logic

### 3.1.2 Block Diagram

[Figure 3-1](#) is a block diagram of the PMM. The PMM consists of several key components:

- Register interface – the PMM control registers are mapped to the device memory space and start at address 0xFFFF0000.
- System Interface – the PMM receives the clocks, resets, errors and all other control signals through this interface.
- PSCON Diagnostic Compare – this block compares the outputs of each primary PSCON and the respective diagnostic PSCON implemented for failsafe safety.
- Self-Test Diagnostic – this block contains the logic to place the PSCON diagnostic compare block in a self-test mode in order to test the failsafe feature.
- Clock management – the PMM provides independent clock gating and handshaking controls for each power domain and also generates the clock domains for each power domain.
- Reset Management – the PMM provides independent reset signals for each power domain.
- Power State Controller (PSCON) – The PSCON is a finite state machine that controls the power sequence of a power domain from one state to another. Each power domain is controlled by one dedicated PSCON.
- Power Domain – A power domain is a group of logic and/or memories which is separated from the global power supply via power switches. These power switches are controlled by the PSCON and can be turned on or off.

Figure 3-1. PMM Block Diagram

## 3.2 Power Domains

Figure 3-2 shows the core and memory power domains implemented on the microcontroller.

This device has 7 separate core power domains:

- PD1 is an always-ON domain and is not controlled by PMM. It contains the CPU as well as other principal modules and the interconnect required for operation of the microcontroller. This domain also includes 64KB of the tightly-coupled RAM. The PD1 can operate on its own even when all the other core power domains are turned off by the PMM. Note that all I/Os are in this always-ON domain as well.

Core power domains PD2 through PD5 and RAM\_PD1 through RAM\_PD2 are controlled by the PMM.

- PD2 contains the Parameter Overlay Module (POM).
- PD3 contains some additional peripheral modules as an enhanced configuration over and above the peripheral set available in PD1. These include a second High-End Timer (NHET2) with its dedicated transfer unit (HTU2), a second Analog-to-Digital Converter (ADC2), a Serial Communication Interface (SCI), an Inter-Integrated Circuit controller (I2C), a third Controller Area Network controller (DCAN3), and a fourth Serial Peripheral Interface module (SPI4).
- PD4 contains the FlexRay controller and its dedicated transfer unit (FTU).
- PD5 contains the Ethernet controller (EMAC), the External Memory Interface (EMIF), as well as some components of the interconnect fabric required by these modules.
- RAM\_PD1 and RAM\_PD2 each contain 64KB of tightly-coupled RAM.

---

### NOTE: Switching of Power Domains

The microcontrollers only support static switching of the power domains. That is, the power domains can be turned ON or OFF one time during device initialization. Once configured, it is not allowed to change the state of a power domain without first asserting a system reset.

---

**Figure 3-2. Core Power Domains**

### 3.3 PMM Operation

It is important to understand some fundamental concepts beforehand.

#### 3.3.1 Power Switch

A power domain gets its power supply via a power switch. The power switch creates a link between the global core supply plane and the local switchable power domain supply. Each power domain uses multiple power switches, which are daisy-chained together.

#### 3.3.2 Power Domain State

Each core power domain can be in one of three states: Active, Idle, or Off.

In the **active** state, a power domain is fully powered with normal supply voltage.

In the **idle** state, all clocks to a power domain are turned off (driven low). The supply voltage is still maintained at the normal level.

In the **off** state, a power domain is completely cut off from the power supply.

#### 3.3.3 Default Power Domain State

The default state of each power domain, except for PD1, is controlled by TI during production testing via programming of individual bits within the reset configuration word in the TI-OTP sector of flash bank 0. This allows each power domain to default to either the active state or the off state.

#### 3.3.4 Disabling a Power Domain Permanently

TI can also permanently disable any power domain, except for PD1. This is also controlled by programming of individual bits within the reset configuration word in the TI-OTP sector of flash bank 0.

#### 3.3.5 Changing Power Domain State

A domain can only change state when commanded by the application. Each domain has an associated 4-bit key to define the intended power state. When the correct key is programmed, the PMM initiates the sequence to transition that domain to the commanded state.

A power state transition is considered complete only when every single power switch for that domain has switched over to the commanded state.

##### 3.3.5.1 Turning a Power Domain Off

It is necessary to turn off all clocks going to a power domain before that domain can be powered down. PMM contains the hardware interlocks to handle this. Each power domain has an associated memory-mapped register which allows the application to turn off clocks to that power domain.

Steps to power down a domain with logic – PD2, PD3, PD4, PD5:

1. Write to the PDCLK\_DISx register to disable all clocks to the power domain.
2. Write 0xA to the LOGICPDONx register to power down the domain.
3. Poll for LOGICPDPWRSTATx to become “00”. The power domain is now powered down.

A power domain with only SRAM macros does not have a clock input, so the sequence is shorter. This applies to RAM\_PD1 and RAM\_PD2 power domains shown in [Figure 3-2](#):

1. Write the correct key to the MEMPDONx register to power down the domain.
2. Poll for MEMPDPWRSTATx to become “00”. The power domain is now powered down.

### 3.3.5.2 Turning a Power Domain On

A power domain can be turned on by writing the correct key to the LOGICPDON or MEMPDON register. PMM will automatically restart the clocks to the power domain once the power is restored if the “automatic clock enable upon wake up” option is selected. If this option is not selected, the application can turn on clocks to the power domain by clearing the PDCLK\_DIS register. The application must poll the DOMAINISON register to ensure that the power has been fully restored before enabling the clocks.

---

**NOTE:** If a power domain has been permanently disabled by TI, the application cannot turn this power domain ON. No error is generated if the application attempts to do so.

---

### 3.3.6 Reset Management

PMM handles the reset sequence for each power domain. When a power domain is turned on from an off state, the PMM will reset the power domain to ensure that all logic begins in its default reset state.

PMM generates nPORRST (power-on reset), nRST (system reset), nPRST (peripheral reset), and nTRST (test / debug logic reset) for each domain.

### 3.3.7 Diagnostic Power State Controller (PSCON)

Each power domain state is controlled by a primary PSCON. There is a second PSCON as well for each power domain. This is the diagnostic PSCON. All power management inputs to a power domain are controlled only by the primary PSCON. All power management outputs from the power domain are fed back to both the primary and the diagnostic PSCON.

The PMM commands both the PSCON identically so that they are always in a lock-step operating mode. A dedicated compare unit checks the outputs of the two PSCON modules on every cycle.

### 3.3.8 PSCON Compare Block

The diagnostic compare block can operate in one of four modes:

#### 3.3.8.1 Lock-Step Mode

This is the default mode of operation of the PSCON compare block. The PSCON diagnostic compare block compares the outputs from the two PSCONs on every cycle. Any mismatch in the PSCON outputs is indicated as a PSCON compare error. This error signal is mapped to the Error Signaling Module's (ESM) Group1 channel 38. The application can define the response to this error.

#### 3.3.8.2 Self-Test Mode

A self-test mechanism is provided to check the PSCON compare logic for faults. The compare error signal output is disabled in self-test mode. The PSCON diagnostic compare block generates two types of patterns during self-test mode: compare match test followed by compare mismatch test. During the self-test, each test pattern is applied on both PSCON signal ports of the PSCON diagnostic compare block and then is clocked for one cycle. The duration of the self-test is 24 cycles. Any detected fault is indicated as a self-test error, mapped to ESM group1 channel 39. If no fault is detected, the self-test complete flag is set.

The application can poll for this flag to be set and then switch the mode of the PSCON compare block back to lock-step mode by writing to the mode key register.

---

**NOTE:** **PSCON operation when compare block is in self-test mode**

When the PSCON compare block is in its self-test mode, both PSCONs continue to function normally. However, there is no comparison done on the PSCON outputs.

---

### Compare match test:

An identical vector is applied to both input ports at the same time, thereby expecting a compare match. If the compare unit produces a mismatch then the self-test error flag is set and the self-test error signal is generated. The compare match test is terminated if a compare mismatch is detected. The compare match test takes 4 cycles to complete when the test passes.

### Compare mismatch test:

A vector with all 1's is applied to the PSCON diagnostic compare block's primary input port and the same input is also applied to the secondary input port but with one bit flipped starting from bit position 0. The unequal vectors should cause the PSCON diagnostic compare block to generate a compare mismatch at bit position 0. In case a mismatch is not detected, a self-test error is indicated. This compare mismatch test algorithm is repeated until every single bit position is verified on both PSCON signal ports.

### 3.3.8.3 Error-Forcing Mode

This mode is designed specifically to ensure that the error signal output from the PSCON compare block is not stuck inactive. In this mode, a test pattern is applied to the PSCON related inputs of the compare logic to force an error. The application can clear the flag for ESM group1 channel 38 once the error is flagged. If the ESM group1 channel 38 flag does not get set, this indicates that the PSCON compare error signal is stuck inactive and cannot be relied upon to detect a PSCON mismatch.

### 3.3.8.4 Self-Test Error-Forcing Mode

In this mode, an error is forced so that the self-test error output from the PSCON compare block is activated. The application can clear the flag for ESM group1 channel 39 once the error is flagged. If the ESM group1 channel 39 flag does not get set, this indicates that the PSCON compare block self-test error signal is stuck inactive and there is no self-test mechanism available for the PSCON compare block.

### 3.3.8.5 PMM Operation During CPU Halt Debug Mode

No compare errors are generated when the CPU is halted in debug mode, regardless of the mode of the diagnostic compare block. No status flags are updated in this mode. Normal operation of the compare block is resumed once the CPU exits the debug mode.

## 3.4 PMM Registers

[Table 3-1](#) lists the memory-mapped registers for the PMM. All register offset addresses not listed in [Table 3-1](#) should be considered as reserved locations and the register contents should not be modified.

**Table 3-1. PMM REGISTERS**

| Offset | Acronym         | Register Name                                     | Section                        |

### 3.4.1 LOGICPDPWCTRL0 Register (offset = 0h) [reset = 0h]

LOGICPDPWCTRL0 is shown in [Figure 3-3](#) and described in [Table 3-2](#).

The default values of the control fields are determined by the device reset configuration word stored in the TI-OTP region of flash bank 0.

### 3.4.7 LOGICPDPWRSTAT1 Register (offset = 44h) [reset = 0h]

LOGICPDPWRSTAT1 is shown in [Figure 3-9](#) and described in [Table 3-8](#).

This is a read-only register. All writes are ignored. The default values of the control fields are determined by the device reset configuration word stored in the TI-OTP region of flash bank 0.

### 3.4.8 LOGICPDPWRSTAT2 Register (offset = 48h) [reset = 0h]

LOGICPDPWRSTAT2 is shown in [Figure 3-10](#) and described in [Table 3-9](#).

This is a read-only register. All writes are ignored. The default values of the control fields are determined by the device reset configuration word stored in the TI-OTP region of flash bank 0.

### 3.4.9 LOGICPDPWRSTAT3 Register (offset = 4Ch) [reset = 0h]

LOGICPDPWRSTAT3 is shown in [Figure 3-11](#) and described in [Table 3-10](#).

This is a read-only register. All writes are ignored. The default values of the control fields are determined by the device reset configuration word stored in the TI-OTP region of flash bank 0.

### 3.4.10 MEMPDWRSTAT0 Register (offset = 80h) [reset = 0h]

MEMPDPWRSTAT0 is shown in Figure 3-12 and described in Table 3-11.

This is a read-only register. All writes are ignored. The default values of the control fields are determined by the device reset configuration word stored in the TI-OTP region of flash bank 0.

### 3.4.11 MEMPDWRSTAT1 Register (offset = 84h) [reset = 0h]

MEMPDPWRSTAT1 is shown in [Figure 3-13](#) and described in [Table 3-12](#).

This is a read-only register. All writes are ignored. The default values of the control fields are determined by the device reset configuration word stored in the TI-OTP region of flash bank 0.

## 4.1 Overview

This chapter describes the overall features of the module which controls the I/O multiplexing on the device. The mapping of control registers to multiplexing options is specified in [Section 4.8](#).

## 4.2 Main Features of I/O Multiplexing Module (IOMM)

The IOMM contains memory-mapped registers (MMR) that control device-specific multiplexed functions. The safety and diagnostic features of the IOMM are:

- Kicker mechanism to protect the MMRs from accidental writes
- Master-id checker to only allow the CPU to write to the MMRs
- Error indication for access violations

## 4.3 Control of Multiplexed Outputs

The signal multiplexing controlled by each memory-mapped control register (PINMMRn) is described in [Table 4-21](#). Each byte in the PINMMRs control the functionality output on a single terminal. Consider the following example for the PINMMR10 control register.

**Figure 4-1. PINMMR10 Control Register, Address = FFFF EB38h**

|          |              |              |             |
|----------|--------------|--------------|-------------|

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

- Consider the multiplexing controlled by PINMMR10[23–16]. These bits control the multiplexing between the EMIF\_nCS[0] and N2HET2[7] on the ball N17 of the 337BGA package for this device. The default function on the N17 ball is EMIF\_nCS[0]. This is dictated by bit 16 of the PINMMR10 register being set.
- If the application wants to use N17 as an N2HET2[7] signal, then bit 16 of PINMMR10 must be cleared and bit 18 must be set.
- Each feature of the output function is determined by the function selected to be output on a terminal.

For example, the ball N17 on the 337BGA package is driven by an output buffer with an 8mA drive strength and which supports the adaptive impedance control mode for reduced electromagnetic emissions. This output buffer has the following signals: A (signal to be output), GZ (output enable), SBEN (Standard Buffer Enable) and LPM (Low Power Mode). Each of these signals is an output of a multiplexor which allows the selected function to control all available features of the output buffer.

- The PINMMR control registers are used to implement a one-hot encoding scheme for selecting the multiplexed function.
  - For example, for the N17 ball on the 337BGA package for this device at least one out of bit 16 or bit 18 must be set.
  - If the application clears both bits 16 and 18, then the default function, EMIF\_nCS[0], will be selected for output on N17.
  - If the application sets both bits 16 and 18, then the default function will be selected for output on N17.

- If the application sets one or more reserved bit(s) within the byte 23–16, then the default function will be selected for output on N17.

Figure 4-2 shows the multiplexing between the output functions for the N17 ball. This terminal uses an 8mA low-EMI output buffer.

**Figure 4-2. Output Multiplexing Example**

#### 4.4 Control of Multiplexed Inputs

The microcontrollers are available in two package options – 337-ball grid array (BGA) and 144-pin Quad Flat Pack (QFP). Input multiplexing is not required for the 337BGA package. For the 144QFP package, some signals have a multiplexor implemented on their input side. The selection between the two input paths is done by a combination of two control registers. These registers are described in Table 4-1.

**Table 4-1. Input Multiplexing on 144QFP Parts**

| Signal     | 144QFP Dedicated Input Pin # | 144QFP Multiplexed Input Pin # | A, Output Control for Muxed Pin | B, Input Control for Muxed Pin |
|------------|------------------------------|--------------------------------|---------------------------------|--------------------------------|
| SPI4SIMO   | –                            | 30                             | PINMMR5[9]                      | PINMMR23[16]                   |
| SPI4SOMI   | –                            | 31                             | PINMMR5[17]                     | PINMMR23[24]                   |

| N2HET1[19] | –                            | 40                             | PINMMR8[9]                      | PINMMR24[24]                   |
| N2HET1[23] | –                            | 96                             | PINMMR12[17]                    | PINMMR25[8]                    |
| N2HET1[25] | –                            | 37                             | PINMMR7[9]                      | PINMMR25[16]                   |
| N2HET1[27] | –                            | 4                              | PINMMR0[26]                     | PINMMR25[24]                   |
| N2HET1[29] | –                            | 3                              | PINMMR0[18]                     | PINMMR26[0]                    |
| N2HET1[31] | –                            | 54                             | PINMMR9[10]                     | PINMMR26[8]                    |
| GIOB[2]    | 142                          | 55                             | PINMMR29[16]                    | PINMMR29[16]                   |

For signals with a “–” in the column for dedicated input pin #, these signals do have a dedicated pad on the die. The default input for these signals comes from the dedicated pad. To be able to drive in the input from the multiplexed pins on the 144QFP package, the IOMM registers need to be configured.

Table 4-1 shows two controls for each of these signals: A and B.

A indicates the control register bit to be set to enable the corresponding signal to be output on the multiplexed pin.

B is another control register bit that is used to select between the dedicated input terminal and the multiplexed pin.

- The input to a module comes from the **dedicated** pad when the condition **[ not(A) or (A AND B) ] = TRUE**.
- The input to a module comes from the **multiplexed** pin when the condition **[ A and not(B) ] = TRUE**.

---

**NOTE: Inputs are broadcast to all multiplexed functions**

The input signals are broadcast to all modules hooked up to a terminal. The application must ensure that modules that are not being used in the application do not react to a change on their input functions. For example, a GIO signal toggle can trigger an interrupt request, when the application actually is using the function multiplexed with this GIO signal.

---

**Figure 4-3. Input Multiplexing Example**

## 4.5 Control of Special Multiplexed Options

Several of the PINMMR registers are used to control specific functions on this microcontroller. These are described now.

### 4.5.1 Control of SDRAM clock (EMIF\_CLK)

PINMMR29[8] is set by default. This blocks the EMIF SDRAM clock signal (EMIF\_CLK) from being output from the microcontroller. If the EMIF is used to connect to an external SDRAM module, then the application must enable the SDRAM clock output by clearing the PINMMR29[8] bit.

### 4.5.2 Control for other EMIF Outputs

There are some EMIF address and control signals that are multiplexed with N2HET2 signals. For applications that require the use of these N2HET2 signals, it is inconvenient if the EMIF starts driving these address and control signals as output after reset is released and before the application can configure the I/O Multiplexing Module registers. Therefore, these EMIF signals are blocked from being output by default. This is done by using the bit 31 of the system module General Purpose Control Register

(GPREG1). This bit is cleared (0) by default. In this condition, these EMIF/N2HET2 terminals are configured as inputs and pulled down. An application that requires the EMIF functionality must set the GPREG1[31] bit. This causes the EMIF address and control signals to then be output on the EMIF/N2HET2 terminals when the EMIF functionality is selected via the IOMM output multiplexing control registers.

#### 4.5.3 Control for Fast Mode for Synchronous and Asynchronous EMIF

The EMIF on this microcontroller implements a "fast mode" for both the synchronous and asynchronous interfaces. There are some critical timing paths on read accesses to external asynchronous as well as synchronous memories. The fast mode allows the clock to the capture flops inside the EMIF module to be pushed in order to capture the incoming data correctly. The fast mode for asynchronous interface is enabled by setting PINMMR29[18] and the fast mode for the synchronous interface is enabled by setting PINMMR29[17].

#### 4.5.4 Control of Ethernet Controller Mode

PINMMR29[24] is set by default. This bit is used to enable the Reduced Media Independent Interface of the Ethernet controller. If the application desires to use the Media Independent Interface of the Ethernet controller, then the PINMMR29[24] must be cleared.

#### 4.5.5 Control of ADC Trigger Events

The microcontrollers contain two Analog-to-Digital Converter modules: ADC1 and ADC2. The ADC conversions can be started using a rising or falling or both edges as the trigger event. Both the ADC modules support up to eight event trigger inputs. There are two sets of these 8 inputs for each ADC. The option for each of these 8 inputs are controlled by registers in the I/O multiplexing module as shown in [Table 4-2](#) and [Table 4-3](#).

**Table 4-2. ADC1 Trigger Event Selection**

| Group Source Select, G1SRC, G2SRC or EVSRC | Event # | Trigger Event Signal      |                                     |                      |            |                                       |
|--------------------------------------------|---------|---------------------------|-------------------------------------|----------------------|------------|---------------------------------------|
|                                            |         | PINMMR30[0] = 1 (default) | PINMMR30[0] = 0 and PINMMR30[1] = 1 |                      |            |                                       |

#### 4.5.6 Control for ADC Event Trigger Signal Generation from eTPWMx Modules

This microcontroller implements 7 eTPWM modules. Each of these modules generate two outputs, SOCA (Start Of Conversion) and SOCB, for use in triggering the on-chip ADC modules. Registers from the I/O multiplexing module are used to control the logic for generation of the eTPWM\_A1, eTPWM\_A2, eTPWM\_AB and eTPWM\_B signals from these eTPWMx\_SOCA and eTPWMx\_SOCB signals.

The logic equations for the 4 outputs from the combinational logic shown in [Figure 4-4](#) are:

- B = SOC1B or SOC2B or SOC3B or SOC4B or SOC5B or SOC6B or SOC7B
- A1 = [ SOC1A and not(SOC1A\_SEL) ]  
[ SOC2A and not(SOC2A\_SEL) ]  
[ SOC3A and not(SOC3A\_SEL) ]  
[ SOC4A and not(SOC4A\_SEL) ]  
[ SOC5A and not(SOC5A\_SEL) ]  
[ SOC6A and not(SOC6A\_SEL) ]  
[ SOC7A and not(SOC7A\_SEL) ]
- A2 = [ SOC1A and SOC1A\_SEL ]

**Figure 4-4. ADC Trigger Event Signal Generation from eTPWMx**

The SOCxA\_SEL signals used in the above logic equations are generated using registers in the I/O multiplexing module.

- PINMMR35[0] defines the value of SOC1A\_SEL. This bit is set by default and can be cleared by the application.
- PINMMR35[8] defines the value of SOC2A\_SEL. This bit is set by default and can be cleared by the application.
- PINMMR35[16] defines the value of SOC3A\_SEL. This bit is set by default and can be cleared by the application.
- PINMMR35[24] defines the value of SOC4A\_SEL. This bit is set by default and can be cleared by the application.
- PINMMR36[0] defines the value of SOC5A\_SEL. This bit is set by default and can be cleared by the application.
- PINMMR36[8] defines the value of SOC6A\_SEL. This bit is set by default and can be cleared by the application.
- PINMMR36[16] defines the value of SOC7A\_SEL. This bit is set by default and can be cleared by the application.

#### 4.5.7 Control for Generating Interrupt Upon External Fault Indication to N2HETx

The N2HET module on this microcontroller allows the application to selectively disable any PWM output from the N2HET module whenever a fault condition is indicated to the N2HET. This fault condition is input to the N2HET module via the N2HETx\_PIN\_nDIS input signal. It is important for the CPU to be notified with an interrupt whenever this fault condition is indicated to the N2HET module.

The PIN\_nDIS signal for the N2HET1 module comes from the GIOA[5] terminal, and the application can enable the interrupt generation for whenever the GIOA[5] terminal is driven low.

The PIN\_nDIS signal for the N2HET2 module comes from the MibSPI3\_nCS[0] / AD2EVT terminal. These signals do not offer the capability of generating an interrupt when they are driven low. Therefore, the input from this terminal can optionally be connected to the GIOB[2] input. This connection is enabled by a register in the I/O multiplexing module. This is the PINMMR29[16].

#### 4.5.8 Control for Enabling Clocks to eTPWMx Modules

The VCLK4 domain is used as the clock for the eTPWMx modules. This clock can be individually gated off when one or more of the eTPWMx modules are not being used.

- PINMMR37[8] is set by default and enables the clock to the eTPWM1. The application can clear this bit to disable the clock to the eTPWM1.
- PINMMR37[16] is set by default and enables the clock to the eTPWM2. The application can clear this bit to disable the clock to the eTPWM2.
- PINMMR37[24] is set by default and enables the clock to the eTPWM3. The application can clear this bit to disable the clock to the eTPWM3.
- PINMMR38[0] is set by default and enables the clock to the eTPWM4. The application can clear this bit to disable the clock to the eTPWM4.
- PINMMR38[8] is set by default and enables the clock to the eTPWM5. The application can clear this bit to disable the clock to the eTPWM5.
- PINMMR38[16] is set by default and enables the clock to the eTPWM6. The application can clear this bit to disable the clock to the eTPWM6.
- PINMMR38[24] is set by default and enables the clock to the eTPWM7. The application can clear this bit to disable the clock to the eTPWM7.

#### 4.5.9 Control for Enabling Clocks to eCAPx Modules

The VCLK4 domain is used as the clock for the eCAPx modules. This clock can be individually gated off when one or more of the eCAPx modules are not being used.

- PINMMR39[0] is set by default and enables the clock to the eCAP1. The application can clear this bit to disable the clock to the eCAP1.
- PINMMR39[8] is set by default and enables the clock to the eCAP2. The application can clear this bit to disable the clock to the eCAP2.
- PINMMR39[16] is set by default and enables the clock to the eCAP3. The application can clear this bit to disable the clock to the eCAP3.
- PINMMR39[24] is set by default and enables the clock to the eCAP4. The application can clear this bit to disable the clock to the eCAP4.
- PINMMR40[0] is set by default and enables the clock to the eCAP5. The application can clear this bit to disable the clock to the eCAP5.
- PINMMR40[8] is set by default and enables the clock to the eCAP6. The application can clear this bit to disable the clock to the eCAP6.

#### 4.5.10 Control for Enabling Clocks to eQEPx Modules

The VCLK4 domain is used as the clock for the eQEPx modules. This clock can be individually gated off when one or more of the eQEPx modules are not being used.

- PINMMR40[16] is set by default and enables the clock to the eQEP1. The application can clear this bit to disable the clock to the eQEP1.
- PINMMR40[24] is set by default and enables the clock to the eQEP2. The application can clear this bit to disable the clock to the eQEP2.

#### 4.5.11 Control for Synchronizing Time Bases for All eTPWMx Modules

The eTPWMx modules implement a mechanism that allows their time bases to be synchronized. This is done by using a signal called TBCLKSYNC, which is a common input to all the eTPWMx modules. This TBCLKSYNC is generated by a register bit in the I/O multiplexing module. PINMMR37[1] is the TBCLKSYNC signal. This bit is clear ('0') by default.

When TBCLKSYNC = 0, the time-base clock of all eTPWMx modules is stopped. This is the default condition.

When TBCLKSYNC = 1, the time-base clocks of all eTPWMx modules are started aligned to the rising edge of the TBCLKSYNC signal.

The correct procedure for enabling and synchronizing the time-base clocks of all the eTPWMx modules is:

1. Enable the clocks to the desired individual eTPWMx modules if they have been disabled
2. Set TBCLKSYNC = 0. This will stop the time-base clocks of any enabled eTPWMx module.
3. Configure the time-base clock prescaler values and desired eTPWM modes.
4. Set TBCLKSYNC = 1.

#### 4.5.12 Control for Synchronizing all eTPWMx Modules to N2HET1 Module Time-Base

Some applications require a synchronized time base for all PWM signals generated by the microcontroller. The N2HET1 module uses a time base that is created by configuring the high-resolution and loop-resolution prescalers in the N2HET1 module control registers. The N2HET1 module outputs the loop-resolution clock signal (N2HET1\_LOOP\_SYNC) so that other timer modules on the microcontroller can use it to synchronize their time bases to the N2HET1 loop-resolution clock.

There is a dedicated connection between the N2HET1 and N2HET2 modules, which allows the N2HET2 to use the N2HET1\_LOOP\_SYNC signal to synchronize its own time base to that of N2HET1.

The seven eTPWMx modules can also optionally use the N2HET1\_LOOP\_SYNC for their time-base synchronization using a specially designed scheme.

**Figure 4-5. Synchronizing eTPWMx Modules to N2HET1 Time-Base**

PINMMR36[25] is used to select between the eTPWM1\_SYNCI and the stretched N2HET1\_LOOP\_SYNC signals.

If PINMMR36[25] = 0, the SYNCI input to the eTPWM1 comes from the eTPWM1\_SYNCI device input terminal. This is the default connection.

If PINMMR36[25] = 1, the SYNCI input to the eTPWM1 comes from the pulse-stretched N2HET1\_LOOP\_SYNC signal.

#### 4.5.13 Control for Input Connections to eTPWMx Modules

The eTPWMx modules take the following signals as input:

- eTPWM1\_SYNCI: external time-base input to the eTPWMx
- nTZ1 through nTZ6: trip-zone inputs to the eTPWMx

Of the six trip-zone inputs, three are input from device terminals while the other three are connected to internal error events. Registers from the I/O multiplexing module are used to control various aspects of these input connections to the eTPWMx modules.

**Table 4-4. Controls for eTPWMx Inputs**

| Input Signal | Control for Asynchronous Input<br>(default connection) | Control for Double-VCLK4-Synchronized Input | Control for Double-VCLK4-Synchronized and 6-VCLK4-Filtered Input |
|--------------|--------------------------------------------------------|---------------------------------------------|------------------------------------------------------------------|
| nTZ1         | PINMMR46[16] = 1                                       | PINMMR46[16] = 0 and<br>PINMMR46[17] = 1    | PINMMR46[17:16] = "00" and<br>PINMMR46[18] = 1                   |
| nTZ2         | PINMMR46[24] = 1                                       | PINMMR46[24] = 0 and<br>PINMMR46[25] = 1    | PINMMR46[25:24] = "00" and<br>PINMMR46[26] = 1                   |
| nTZ3         | PINMMR47[0] = 1                                        | PINMMR47[0] = 0 and<br>PINMMR47[1] = 1      | PINMMR47[1:0] = "00" and<br>PINMMR47[2] = 1                      |
| eTPWM1_SYNCI | PINMMR47[8] = 1                                        | PINMMR47[8] = 0 and<br>PINMMR47[9] = 1      | PINMMR47[9:8] = "00" and<br>PINMMR47[10] = 1                     |

Of the three internal error events for the trip-zone inputs, nTZ4 is connected to the eQEPx error output signal. There are two eQEP modules on this microcontroller, and registers in the I/O multiplexing module are used to allow a flexible scheme for the connection between the eQEPx error signal and the nTZ4 inputs of the eTPWMx modules.

**Table 4-5. Controls for eQEPx\_ERROR Connection to eTPWMx nTZ4 Inputs**

| eTPWMx Module | Control for nTZ4 =<br>not(eQEP1ERR or<br>eQEP2ERR)<br>(default connection) | Control for nTZ4 =<br>not(eQEP1ERR)      | Control for nTZ4 =<br>not(eQEP2ERR)            |
|---------------|----------------------------------------------------------------------------|------------------------------------------|------------------------------------------------|
| eTPWM1        | PINMMR41[0] = 1                                                            | PINMMR41[0] = 0 and<br>PINMMR41[1] = 1   | PINMMR41[1:0] = "00" and<br>PINMMR41[2] = 1    |
| eTPWM2        | PINMMR41[8] = 1                                                            | PINMMR41[8] = 0 and<br>PINMMR41[9] = 1   | PINMMR41[9:8] = "00" and<br>PINMMR41[10] = 1   |
| eTPWM3        | PINMMR41[16] = 1                                                           | PINMMR41[16] = 0 and<br>PINMMR41[17] = 1 | PINMMR41[17:16] = "00" and<br>PINMMR41[18] = 1 |
| eTPWM4        | PINMMR41[24] = 1                                                           | PINMMR41[24] = 0 and<br>PINMMR41[25] = 1 | PINMMR41[25:24] = "00" and<br>PINMMR41[26] = 1 |
| eTPWM5        | PINMMR42[0] = 1                                                            | PINMMR42[0] = 0 and<br>PINMMR42[1] = 1   | PINMMR42[1:0] = "00" and<br>PINMMR42[2] = 1    |
| eTPWM6        | PINMMR42[8] = 1                                                            | PINMMR42[8] = 0 and<br>PINMMR42[9] = 1   | PINMMR42[9:8] = "00" and<br>PINMMR42[10] = 1   |
| eTPWM7        | PINMMR42[16] = 1                                                           | PINMMR42[16] = 0 and<br>PINMMR42[17] = 1 | PINMMR42[17:16] = "00" and<br>PINMMR42[18] = 1 |

#### 4.5.14 Control for Input Connections to eCAPx Modules

Each eCAPx module has a single input from the device terminals. This input can be connected to the eCAPx module in two ways:

1. Double-synchronized using VCLK4, or
2. Double-synchronized using VCLK4 and then filtered through a 6-VCLK4-cycle counter

Registers in the I/O multiplexing module are used to control these input connections for each eCAPx module.

**Table 4-6. Controls for eCAPx Inputs**

| eCAPx Input | Control for Double-VCLK4-Synchronized Input (default connection) | Control for Double-VCLK4-Synchronized and 6-VCLK4-Filtered Input |
|-------------|------------------------------------------------------------------|------------------------------------------------------------------|
| eCAP1       | PINMMR43[0] = 0                                                  | PINMMR43[0] = 0 and PINMMR43[1] = 1                              |
| eCAP2       | PINMMR43[8] = 0                                                  | PINMMR43[8] = 0 and PINMMR43[9] = 1                              |
| eCAP3       | PINMMR43[16] = 0                                                 | PINMMR43[16] = 0 and PINMMR43[17] = 1                            |
| eCAP4       | PINMMR43[24] = 0                                                 | PINMMR43[24] = 0 and PINMMR43[25] = 1                            |
| eCAP5       | PINMMR44[0] = 0                                                  | PINMMR44[0] = 0 and PINMMR44[1] = 1                              |
| eCAP6       | PINMMR44[8] = 0                                                  | PINMMR44[8] = 0 and PINMMR44[9] = 1                              |

#### 4.5.15 Control for Input Connections to eQEPx Modules

Each eQEPx module has four inputs from the device terminals. These inputs can be connected to the eQEPx module in two ways:

1. Double-synchronized using VCLK4, or
2. Double-synchronized using VCLK4 and then filtered through a 6-VCLK4-cycle counter

Registers in the I/O multiplexing module are used to control these input connections for each eQEPx module.

**Table 4-7. Controls for eQEPx Inputs**

| eQEPx Input | Control for Double-VCLK4-Synchronized Input (default connection) | Control for Double-VCLK4-Synchronized and 6-VCLK4-Filtered Input |
|-------------|------------------------------------------------------------------|------------------------------------------------------------------|
| eQEP1A      | PINMMR44[16] = 0                                                 | PINMMR44[16] = 0 and PINMMR44[17] = 1                            |
| eQEP1B      | PINMMR44[24] = 0                                                 | PINMMR44[24] = 0 and PINMMR44[25] = 1                            |
| eQEP1I      | PINMMR45[0] = 0                                                  | PINMMR45[0] = 0 and PINMMR45[1] = 1                              |
| eQEP1S      | PINMMR45[8] = 0                                                  | PINMMR45[8] = 0 and PINMMR45[9] = 1                              |
| eQEP2A      | PINMMR45[16] = 0                                                 | PINMMR45[16] = 0 and PINMMR45[17] = 1                            |
| eQEP2B      | PINMMR45[24] = 0                                                 | PINMMR45[24] = 0 and PINMMR45[25] = 1                            |
| eQEP2I      | PINMMR46[0] = 0                                                  | PINMMR46[0] = 0 and PINMMR46[1] = 1                              |
| eQEP2S      | PINMMR46[8] = 0                                                  | PINMMR46[8] = 0 and PINMMR46[9] = 1                              |

## 4.6 Safety Features

The IOMM supports certain safety functions that are designed to prevent unintentional changes to the I/O multiplexing configuration. These are described in the following sections.

### 4.6.1 Locking Mechanism for Memory-Mapped Registers

The IOMM contains a mechanism to prevent any spurious writes from changing any of the PINMMR values. The PINMMRs are locked by default and after any system reset. None of the PINMMRs can be written under this condition. The application can read any of the IOMM registers regardless of the state of the locking mechanism.

- **Enabling Write Access to the PINMMRs**

To enable write access to the PINMMRs, the CPU must write 0x83e70b13 to the kick0 register followed by a write of 0x95a4f1e0 to the kick1 register.

- **Disabling Write Access to the PINMMRs**

It is recommended to disable write access to the PINMMRs once the I/O multiplexing configuration is completed. This can be done by:

- writing any other data value to either of the kick registers, or
- restarting the unlock sequence by writing 0x83e70b13 to the kick0 register

---

**NOTE: No Error On Write to Locked PINMMRs**

There is no error response on any write accesses to the PINMMRs when write access is disabled. None of the PINMMRs change state due to this write.

---

### 4.6.2 Master ID Check

Each bus transaction to the IOMM has an associated master ID value. Master ID values are unique to each bus master. The IOMM only allows write accessed by the CPU bus master. Writes by other bus masters will generate a bus error response and the states of the IOMM registers are not affected.

### 4.6.3 Error Conditions

The IOMM generates one error signal that is mapped to the Error Signaling Module's Group 1, channel 37. This error signal is generated under either of the following two conditions:

- Address Error – occurs when there is a read or a write access to an un-implemented memory location within the IOMM register frame.
- Protection Error – occurs when the CPU writes to an IOMM register while not in a privileged mode of operation.

## 4.7 IOMM Registers

Table 4-8 lists the memory-mapped registers for the IOMM. All register offset addresses not listed in Table 4-8 should be considered as reserved locations and the register contents should not be modified.

**Table 4-8. IOMM REGISTERS**

| Offset    | Acronym                | Register Name                         | Section                       |
|-----------|------------------------|---------------------------------------|-------------------------------|
| FFFFEA00h | REVISION_REG           | Revision Register                     | <a href="#">Section 4.7.1</a> |

### 4.7.1 REVISION\_REG Register (offset = FFFFEA00h) [reset = 4E840102h]

REVISION\_REG is shown in [Figure 4-6](#) and described in [Table 4-9](#).

This is a read-only register that provides the revision information about the I/O Multiplexing Module (IOMM).

**Figure 4-6. REVISION\_REG Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 4-9. REVISION\_REG Register Field Descriptions**

| Bit   | Field      | Type | Reset | Description                  |
|-------|------------|------|-------|------------------------------|
| 31-30 | REV_SCHEME | R    | 1h    | Revision Scheme, value = 01. |

| 5-0   | REV_MINOR  | R    | 2h    | Minor Revision, value = 2h.  |

### 4.7.2 ENDIAN\_REG Register (offset = FFFFEA20h) [reset = 0h]

ENDIAN\_REG is shown in [Figure 4-7](#) and described in [Table 4-10](#).

This is a read-only register that reflects the state of the device endianness.

**Figure 4-7. ENDIAN\_REG Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 4-10. ENDIAN\_REG Register Field Descriptions**

| Bit  | Field    | Type | Reset | Description                                                                                                          |

#### 4.7.3 KICK\_REG0 Register (offset = FFFFEA38h) [reset = 0h]

KICK\_REG0 is shown in [Figure 4-8](#) and described in [Table 4-11](#).

This register must be written by the CPU in a privileged mode of operation. It forms the first part of the unlock sequence for being able to update the I/O multiplexing control registers (PINMMRnn).

### Figure 4-8. KICK\_REG0 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

### Table 4-11. KICK\_REG0 Register Field Descriptions

| Bit  | Field | Type | Reset | Description                                                                                                                                       |
|------|-------|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | KICK0 | R/W  | 0h    | Kicker 0 Register. The value 83E7 0B13h must be written to KICK0 as part of the process to unlock the CPU write access to the PINMMRnn registers. |

#### 4.7.4 KICK\_REG1 Register (offset = FFFFEA3Ch) [reset = 0h]

KICK\_REG1 is shown in [Figure 4-9](#) and described in [Table 4-12](#).

This register must be written by the CPU in a privileged mode of operation. It forms the second part of the unlock sequence for being able to update the I/O multiplexing control registers (PINMMRnn).

**Figure 4-9. KICK\_REG1 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 4-12. KICK\_REG1 Register Field Descriptions**

| Bit  | Field | Type | Reset | Description                                                                                                                                           |
|------|-------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | KICK1 | R/W  | 0h    | Kicker 1 Register. The value 95A4 F1E0h must be written to the KICK1 as part of the process to unlock the CPU write access to the PINMMRnn registers. |

#### 4.7.5 ERR\_RAW\_STATUS\_REG Register (offset = FFFFEAE0h) [reset = 0h]

ERR\_RAW\_STATUS\_REG is shown in [Figure 4-10](#) and described in [Table 4-13](#).

This register shows the statuses of the error conditions (before enabling) and allows setting the status. The IOMM module error signal is connected to the device's Error Signaling Module (ESM) group1 channel 37. The application can choose to generate an interrupt whenever this ESM channel flag gets set. This interrupt service routine can then read this Error Raw Status Register to determine the actual cause of the error condition. The Error Raw Status register is also writable by the application in order to test the ESM signaling and interrupt generation mechanism.

**Figure 4-10. ERR\_RAW\_STATUS\_REG Register**

### 4.7.9 FAULT\_ADDRESS\_REG Register (offset = FFFFEAF4h) [reset = 0h]

FAULT\_ADDRESS\_REG is shown in [Figure 4-14](#) and described in [Table 4-17](#).

This register holds the address of the first fault transfer.

**Figure 4-14. FAULT\_ADDRESS\_REG Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 4-17. FAULT\_ADDRESS\_REG Register Field Descriptions**

| Bit  | Field      | Type | Reset | Description                                                                                                       |
|------|------------|------|-------|-------------------------------------------------------------------------------------------------------------------|
| 31-0 | FAULT_ADDR | R/W  | 0h    | Fault Address. This field captures the fault address in case of an address error or a protection error condition. |

#### 4.7.10 FAULT\_STATUS\_REG Register (offset = FFFFEAF8h) [reset = 0h]

FAULT\_STATUS\_REG is shown in [Figure 4-15](#) and described in [Table 4-18](#).

This register holds the status and attributes of the first fault transfer.

**Figure 4-15. FAULT\_STATUS\_REG Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 4-18. FAULT\_STATUS\_REG Register Field Descriptions**

#### 4.7.11 FAULT\_CLEAR\_REG Register (offset = FFFFEAFCh) [reset = 0h]

FAULT\_CLEAR\_REG is shown in [Figure 4-16](#) and described in [Table 4-19](#).

This register allows the application to clear the current fault so that another can be captured when 1 is written to this register.

**Figure 4-16. FAULT\_CLEAR\_REG Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 4-19. FAULT\_CLEAR\_REG Register Field Descriptions**

#### 4.7.12 PINMMR0 to PINMMR47 Register (offset = FFFEB10h to FFFEBCh) [reset = 1010101h]

PINMMR0 to PINMMR47 is shown in [Figure 4-17](#) and described in [Table 4-20](#).

These registers control the multiplexing of the functionality available on each pad as well as some special multiplexing schemes for specific functionalities on the microcontroller. There are 48 such registers PINMMR0 through PINMMR47. Each 8-bit field of a PINMMR register controls the functionality of a single ball/pin. The mapping between the PINMMRx control registers and the functionality selected on a given terminal is defined in .

**Figure 4-17. PINMMR0 to PINMMR47 Register**

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

**Table 4-20. PINMMR0 to PINMMR47 Register Field Descriptions**

| Bit   | Field         | Type | Reset | Description                                                                                                                                                                                              |
|-------|---------------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | PINMMRx_31_24 | R/W  | 1h    | Each of these byte-fields control the functionality on a given ball/pin. Please refer to <a href="#">Table 4-21</a> for a list of multiplexed signals. This list is sorted by the control register used. |

| 15-8  | PINMMRx_15_8  | R/W  | 1h    | Each of these byte-fields control the functionality on a given ball/pin. Please refer to <a href="#">Table 4-21</a> for a list of multiplexed signals. This list is sorted by the control register used. |
| 7-0   | PINMMRx_7_0   | R/W  | 1h    | Each of these byte-fields control the functionality on a given ball/pin. Please refer to <a href="#">Table 4-21</a> for a list of multiplexed signals. This list is sorted by the control register used. |

## 4.8 Output Multiplexing and Control

The device output terminals are shared between several different functions. The controls for these outputs are listed in [Table 4-21](#).

**Table 4-21. Output Multiplexing and Control**

## ***F021 Flash Module Controller***

---

---

The Flash electrically erasable programmable read-only memory module is a type of nonvolatile memory which has fast read access times and is able to be reprogrammed in the field or in the application. This chapter describes the F021 Flash module controller (FMC).

## 5.1 Overview

The F021 Flash is used to provide non-volatile memory for instruction execution or data storage. The Flash can be electrically programmed and erased many times to ease code development.

Refer the following documents for support in how to initialize and use the on-chip Flash and its API:

- *Initialization of Hercules ARM Cortex-R4F Microcontrollers* (literature number [SPNA106](#))
- *F021 (Texas Instruments 65nm Flash) Flash API Reference Guide* (literature number [SPNU501](#))

### 5.1.1 Features

- Read, program and erase with a single 3.3 V supply voltage
- Supports error detection and correction
  - Single Error Correction and Double Error Detection (SECCDED)
  - Error Correction Code (ECC) is evaluated in the CPU for the main Flash bank arrays and in the Flash Wrapper for the EEPROM emulation Flash banks
  - Address bits included in ECC calculation
- Provides different read modes to optimize performance and verify the integrity of Flash contents
- Provides built-in power mode control logic
- Integrated program/erase state machine
  - Simplifies software algorithms
  - Supports simultaneous read access on a bank while performing a write or erase operation on any one of the remaining banks
  - Suspend command allows read access to a sector being programmed/erased
  - Fast erase and program times (for details, see the device-specific data sheet)

For the actual size of the Flash memory for the device, see the device-specific data sheet.

### 5.1.2 Definition of Terms

Terms used in this document have the following meaning:

- BAGP (Bank Active Grace Period): Time (in HCLK cycles) from the most recent Flash access of a particular bank until that bank enters fallback power mode. This reduces power consumption by the Flash. However, it can also increase access time.
- bw - Normal data space bank data width of a Flash bank. The bw is 128 bits (144 bits including the error correction bits).
- bwe - EEPROM emulation bank is 128 bit wide (144 bits including the error correction bits).
- Charge pump: Voltage generators and associated control (logic, oscillator, and bandgap, for example).
- CSM: Program/erase command state machine
- Fallback power mode: The power mode (active, standby or sleep, depending on which mode is selected) into which a bank or the charge pump falls back each time the active grace period expires.
- Flash bank: A group of Flash sectors which share input/output buffers, data paths, sense amplifiers, and control logic.
- FEE - Flash EEPROM Emulation. Features on the FMC to support using a Flash type memory in place of an EEPROM Flash memory. EEPROM is erasable by the word while this Flash memory is only erasable by the sector. The FEE bank is accessible only through Bus 2 in a special address range and always resides in bank 7.
- Flash module: Flash banks, charge pump, and Flash wrapper.
- Flash wrapper: Power and mode control logic, data path, wait logic, and write/erase state machines.
- FMC - Flash Module Controller.
- Command - A sequence of coded instructions to Flash module to execute a certain task.

- FSM (Flash State Machine) - State machine which parses and decodes FSM commands. It executes embedded algorithms and generates control signals to both Flash bank and charge pump during the actual program/erase operation.
- OTP (one-time programmable): A program-only-once Flash sector (cannot be erased)
- PAGP (Pump Active Grace Period): Time (in HCLK cycles) from when the last of the banks have entered fallback power mode until the pump enters a fallback power mode. This can reduce power consumption by the Flash; however, it can also increase access time.
- Pipeline mode: The mode in which Flash is read 128 bits (+ 16 bit ECC) at a time, providing higher throughput.
- Sector: A contiguous region of Flash memory which must be erased simultaneously.
- Wide\_Word - the width of the data output from the Flash bank. This is 144 bits wide for main Flash and for the FEE bank.
- Standard read mode: The mode assumed when the pipeline mode is disabled. Physically, 128 (+ 16 bit ECC) is read at a time. However, only 32 bits of data is used while the other bits of data are discarded.
- Read Margin 1 mode: More stringent read mode designed for early detection of marginally erased bits.
- Read Margin 0 mode: More stringent read mode designed for early detection of marginally programmed bits.

### 5.1.3 F021 Flash Tools

Texas Instruments provides the following tools for F021 Flash:

- [nowECC](#) Generation Tool - to generate the Flash ECC from the Flash data.
- [nowFLASH](#) Programming Tool - to erase/program/verify the device Flash content through JTAG.
- Code Composer Studio - the development environment with integrated Flash programming capabilities.
- F021 Flash API Library - a set of software peripheral functions to program/erase the Flash module. Refer to *F021 Flash API Reference Guide* (literature number [SPNU501](#)) for more information.

## 5.2 Default Flash Configuration

At power up, the Flash module state exhibits the following properties:

- Wait states are set to 1 data wait state and 0 address wait states
- Pipeline mode is disabled
- The Flash content is protected from modification
- Power modes are set to *Active* (no power savings)
- The boot code must initialize the wait states (including data wait states and address wait states) and the desired pipeline mode by initializing the FRDCNTL register to achieve the optimum system performance. This needs to be done before switching to the final device operating frequency. Refer to *Initialization of Hercules ARM Cortex-R4F Microcontrollers* (literature number [SPNA106](#)) for more information.

### 5.3 SECDED

The Flash memory can be protected by Single Error Correction Double Error Detection (SECDED). The main program memory is protected by the SECDED circuit inside of the Cortex R4 CPU. All OTP and the FEE memory (bank 7) is protected by SECDED logic in the flash wrapper.

#### 5.3.1 SECDED Initialization

Flash error detection and correction is not enabled at reset. To enable SECDED, error correction detection must be enabled in the flash wrapper, the CPU event bus must be enabled and SECDED must be enabled within the CPU. Refer to *Initialization of Hercules ARM Cortex-R4F Microcontrollers* (literature number [SPNA106](#)) for information on these steps.

The ECC values for all of the ATCM program memory space (flash banks 0 through 6) must be programmed into the flash before SECDED is enabled. This can be done by generating the correct values of the ECC with an external tool such as [nowECC](#) or may be generated by the programming tool. The Cortex R4 CPU may generate speculative fetches to any location within the ATCM memory space. A speculative fetch to a location with invalid ECC, which is subsequently not used, will not create an abort, but will set the ESM flags for a correctable or uncorrectable error. An uncorrectable error will unconditionally cause the nERROR pin to toggle low. Therefore care must be taken to generate the correct ECC for the entire ATCM space including the holes between sections and any unused or blank flash areas.

The Cortex R4 CPU does not generate speculative fetches into the address space of bank 7, the EEPROM Emulation flash. It is only necessary to initialize the ECC values of the locations which will be intentionally read by the CPU or other bus masters.

### 5.3.2 ECC Encoding

Nineteen address lines are also included in the ECC calculation. A failure of a single address line inside of the bank will be treated as an uncorrectable error. The ECC encoding is show in [Table 5-1](#). Bits 31:0 come from the word at the address ending in 0x0 or 0x8, Bits 63:31 come from the word at the address ending in 0x4 or 0xC.

**Table 5-1. ECC Encoding for BE32 Devices**

<sup>(1)</sup> For Odd parity, XOR a 1 to the row's XOR result. For even Parity, use the row's XOR result directly.

<sup>(2)</sup> Each ECC[x] bit represents the XOR of all the address and data bits marked with x in the same row.

### 5.3.3 Syndrome Table: Decode to Bit in Error

The syndrome is a 8 bit value which decodes to the bit in error. The bit in error can be a bit among the 64 data bits, the 19 address bits or a bit among the 8 ECC check bits. A syndrome value of 00000000 indicates there is no error. Any other syndrome combinations not shown in the table are un-correctable multi-bit error. Errors of three or more bits may escape detection. The syndrome decoding is shown in Table 5-2.

**Table 5-2. Syndrome Table, Decode to Bit in Error**

|  |                            |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |  |

- Axx - Single bit address error, uncorrectable
- D - Double bit error, uncorrectable
- M - Multibit errors, uncorrectable

## 5.4 Memory Map

The Flash module contains the program memory, which is mapped starting at location zero, and one Customer OTP sector and one TI OTP sector per bank. The Customer OTP sectors may be programmed by the customer, but cannot be erased. They are typically blank in new parts. The TI OTP sectors are used to contain manufacturing information. They may be read by the customer but can not be programmed or erased. The TI OTP sectors contain settings used by the Flash API to setup the Flash state machine for erase and program operations.

All of these OTP regions are memory mapped to facilitate ease of access by the CPU. They are memory mapped to an offset starting at F000 0000h in the CPU's memory map.

The RWAIT value is used to define the number of wait states for the program memory flash. The EWAIT value is used to define the number of wait states for the data flash in bank 7. Bank 7 starting at offset F020 0000h is dedicated for data storages such as EEPROM Emulation.

### 5.4.1 Location of Flash ECC bits

The flash ECC bits can be read starting at address 0xF0040000. The ECC bits are packed in their memory space as shown in [Figure 5-1](#). The ECC bytes must be read as bytes or halfwords.

**Figure 5-1. ECC Byte Mapping**

## 5.4.2 OTP Memory

### 5.4.2.1 Flash Bank and Sector Sizes

Flash Bank/Sectoring information can be determined from the device-specific datasheet or can be computed by reading locations in the TI OTP and FMC registers.

The number of banks, which banks are available, and the number of sectors for bank 0 can be read from TI OTP location F008 0158h as show in [Figure 5-2](#) and described in [Table 5-4](#).

**Figure 5-2. TI OTP Bank 0 Sector Information (F008 0158h)**

|          |    |                |    |
|----------|----|----------------|----|
| 31       | 24 | 23             | 16 |
| Reserved |    | BX_NUM_Sectors |    |
| R        |    | R              |    |
| 15       | 8  | 7              | 0  |
| Reserved |    | BX_Sector_Size |    |
| R        |    | R              |    |

LEGEND: R = Read only

**Table 5-4. TI OTP Bank 0 Sector Information Field Descriptions**

| Bit   | Field          | Value   | Description                           |
|-------|----------------|---------|---------------------------------------|
| 31-24 | Reserved       | 0       | Reserved. All bits will be read as 0. |
| 23-16 | BX_NUM_Sectors | 0-FFFFh | Number of sectors in bank.            |
| 15-8  | Reserved       | 0       | Reserved                              |
| 7-0   | BX_Sector_Size | 0-FFh   | Number of banks on this part.         |

The bank sector information is repeated once for each bank in the device. The number of sectors is unique for each bank. The number of banks and which banks are implemented is repeated in each location. Use the TI OTP information for bank 0 to determine which banks are in the device, and then read the number of sectors for each bank using the TI OTP locations shown in [Table 5-5](#).

**Table 5-5. TI OTP Sector Information Address**

| Bank | TI OTP Address |
|------|----------------|
| 0    | F008 0158h     |
| 1    | F008 2158h     |
| 2    | F008 4158h     |
| 3    | F008 6158h     |
| 4    | F008 8158h     |
| 5    | F008 A158h     |
| 6    | F008 C158h     |
| 7    | F008 E158h     |

### 5.4.2.2 Package and Memory Size

Package and memory size information can be determined from the device-specific datasheet, or can be computed by reading locations in the TI OTP Bank 0 registers.

The package and memory size can be read from TI OTP location F008 015Ch as show in [Figure 5-3](#) and described in [Table 5-6](#).

**Figure 5-3. TI OTP Bank 0 Package and Memory Size Information (F008 015Ch)**

|             |    |         |    |
|-------------|----|---------|----|
| 31          | 28 | 27      | 16 |
| Reserved    |    | PACKAGE |    |
| R           |    | R       |    |
| 15          | 0  |         |    |
| MEMORY_SIZE |    |         |    |
| R           |    |         |    |

LEGEND: R = Read only

**Table 5-6. TI OTP Bank 0 Package and Memory Size Information Field Descriptions**

| Bit   | Field       | Description                  |
|-------|-------------|------------------------------|
| 31-28 | Reserved    | Reserved                     |
| 27-16 | PACKAGE     | Count of pins in the package |
| 15-0  | MEMORY_SIZE | Flash memory size in Kbytes  |

### 5.4.2.3 LPO Trim and Max HCLK

The HF LPO trim solution, LF LPO trim solution and maximum HCLK frequency can be read from TI OTP location F008 01B4h as show in [Figure 5-4](#) and described in [Table 5-7](#).

**Figure 5-4. TI OTP Bank 0 LPO Trim and Max HCLK Information (F008 01B4h)**

|            |    |            |    |
|------------|----|------------|----|
| 31         | 24 | 23         | 16 |
| HFLPO_TRIM |    | LFLPO_TRIM |    |
| R          |    | R          |    |
| 15         | 0  |            |    |
| MAX_HCLK   |    |            |    |
| R          |    |            |    |

LEGEND: R = Read only

**Table 5-7. TI OTP Bank 0 LPO Trim and Max HCLK Information Field Descriptions**

| Bit   | Field      | Description          |
|-------|------------|----------------------|
| 31-24 | HFLPO_TRIM | HF LPO Trim Solution |
| 23-16 | LFLPO_TRIM | LF LPO Trim Solution |
| 15-0  | MAX_HCLK   | Maximum HCLK Speed   |

#### 5.4.2.4 Part Number Symbolization

Device part number symbolization information can be determined from the device-specific datasheet or can be computed by reading locations in the TI OTP bank 0 registers.

The device part number symbolization can be read from TI OTP bank 0 location F008 01E0h through F008 01FFh as show in [Figure 5-5](#) and described in [Table 5-8](#).

**Figure 5-5. TI OTP Bank 0 Symbolization Information (F008 01E0h-F008 01FFh)**

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|

|      |       | 0x53                | TMS                                                                   |
|      | x     | 0x41                | Silicon Revision A                                                    |
|      |       | 0x42                | Silicon Revision B                                                    |

## 5.5 Power On, Power Off, and Reset Considerations

### 5.5.1 Error Checking at Power On

As the device is coming out of the device reset sequence the flash wrapper reads two configuration words from the TI OTP section of bank zero, the hardware configuration word at address 0xF0080140 and then the AJSM visible password at address 0xF0000000. During these reads ECC is enabled. Single bit errors are corrected and generate an ESM group 1 channel 6 error event. The first failing address will be latched in the FCOR\_ERR\_ADD register along with the bit position in FCOR\_ERR\_POS register and the FEDACSTATUS register flags will be updated to indicate the type of error. Uncorrectable errors will generate an ESM group 3 channel 7 error event, the ERROR pin will be activated, the first failing address will be latched in the FUNC\_ERR\_ADD register and the FEDACSTATUS register flags will be updated to indicate the type of error.

### 5.5.2 Flash Integrity when Reset while Programming or Erasing

If a device is reset while programming, then the bits being programmed when reset is asserted are indeterminate, however the other bits in the flash are not disturbed. Likewise, If the device is reset while being erased, the sector or sectors being erased will have indeterminate bits, however the other sectors in the same bank, and the other banks will not be disturbed.

### 5.5.3 Flash Integrity at Power Off

If power is lost during a programming or erase operation, a power-on reset must be asserted before the core supply voltage drops below specification. The PORRST pin has a glitch filter which means that the PORRST pin must be asserted low  $t_{(nPORRST)}$  (2us) before the core supply drops below  $V_{CC\_MIN}$  (1.14V). If this requirement is met, then the bits being programmed when PORRST goes low are indeterminate, however the other bits in the flash are not disturbed. Likewise, If this requirement is met, and PORRST is asserted while erasing, the sector or sectors being erased will have indeterminate bits, however the other sectors in the same bank, and the other banks will not be disturbed.

## 5.6 Emulation and SIL3 Diagnostic Modes

### 5.6.1 System Emulation

During emulation when SUSPEND signal is high, the data read from memory is still passed to SECEDED for correction if ECC\_ENABLE is active. If a correctable error is detected then it is corrected but error event is not generated and error occurrence counter is not incremented if in profiling mode. If a double error is detected then the raw data is returned without generating double error signal.

The SUSPEND signal can be disabled by using the SUSP\_IGNORE bit in FEDACCTRL1 register. The SUSPEND signal should not be confused with the suspend\_now operation for the FSM.

### 5.6.2 Diagnostic Mode

Flash wrapper can be put in diagnostic mode to verify various logic. There are multiple diagnostic modes supported by the wrapper. A specific diagnostic mode is selected via DIAGMODE[2:0] control bits.

Diagnostic mode is only enabled via a 4-bit key stored in DIAG\_EN\_KEY[3:0]. Only DIAG\_EN\_KEY=0101 will enable any diagnostic mode and all diagnostic modes use the DIAG\_TRIG to initiate the action.

All tests will run from any pipeline mode. Some of the diagnostic modes can corrupt the flash data access, and generate errors as part of the test. Running in non-pipeline may minimize some of these conditions.

For all modes it is best to follow this sequence.

1. Write 0101 to the DIAG\_EN\_KEY register and set the desired DIAG\_MODE. This will block many UERR sources.
2. Set any data registers needed for this mode.
3. Write a one to the DIAG\_TRIG to initiate the action and allow UERRs to happen for one cycle.
4. Write 1010 to DIAG\_EN\_KEY to exit the diagnostic modes.

When the CONF\_TYPE is 5 then the ECC logic is in the CPU and most of diagnostic modes are removed. Some because the logic they test no longer exists and the rest because the path is validated via the ECC path to the CPU.

**Table 5-9. DIAGMODE Encoding**

| Mode | DIAGMODE Bits |   |   | Description                                                       |
|------|---------------|---|---|-------------------------------------------------------------------|
| 0    | 0             | 0 | 0 | Diagnostic mode is disabled. Same as DIAG_EN_KEY not equal to 5h. |
| 1    | 0             | 0 | 1 | ECC Data correction test mode.                                    |
| 2    | 0             | 1 | 0 | ECC Syndrome reporting test mode.                                 |
| 3    | 0             | 1 | 1 | ECC Malfunction test mode 1 (same data mode)                      |
| 4    | 1             | 0 | 0 | ECC Malfunction test mode 2 (inverted data mode)                  |
| 5    | 1             | 0 | 1 | Address Tag Register test mode                                    |
| 6    | 1             | 1 | 0 | Reserved                                                          |
| 7    | 1             | 1 | 1 | ECC Data Correction                                               |

### 5.6.2.1 ECC Data Correction Mode 1

This diagnostic mode can be enabled while ECC logic is also enabled for normal bank read. The flash wrapper will arbitrate the usage of the ECC logic if a conflict occurs between a normal bank read and diagnostic checking.

When in diagnostic data correction mode, FEMU\_xxxx registers contain the 64-bit EEPROM emulation data register, the 19-bit emulation address register and the 8-bit emulation check-bit register. These values are used to enter diagnostic data to exercise the SECDED logic. The user can apply a value with an error in any bit location. When the DIAG\_TRIG is set, the SECDED calculation is done and the corrected values are saved back into the same FEMU\_xxxx registers. The error position register is also updated to indicate the bit position in error. Either ERR\_ONE\_FLG or ERR\_ZERO\_FLG bit is set when a correctable error is detected. The D\_COR\_ERR bit will be also be set in FEDACSTATUS. For un-correctable error the double/multi bit error status bit ECC\_MUL\_ERR is set as well as the D\_UNC\_ERR bit in the same register. Status bits should be cleared by the user before applying a new diagnostic data.

It takes multiple CPU transactions to preload the registers with diagnostic values. During this time, the result of the diagnostic logic such as comparator can change. User should apply a trigger by setting DIAG\_TRIG bit to 1 as a qualifier after all registers are loaded with intended values. The DIAG\_TRIG serves to validate the diagnostic result. Only when DIAG\_TRIG is high and a failing result in the diagnostic logic will update the corresponding status flag and the position register.

### 5.6.2.2 ECC Syndrome Report Mode 2: DIAGMODE = 2

When in diagnostic syndrome reporting mode, the resulting syndrome calculated by SECDED is captured into the ECC check-bit register FEMU\_ECC. The syndrome can be read by the user and compare with a known syndrome value. Diagnostic data in FEMU\_DxSW and FEMU\_ADDR is not corrected and the error position register is not updated. The FEDACSTATUS error bits are not updated during this mode. See [Figure 5-6](#).

For devices with ECC\_IN\_CPU (CONF\_TYPE=5), the resulting FEMU\_ECC value will represent the 32-bit byte swapped values. Here, bytes 7654\_3210 are rearranged to 4567\_0123. For instance, if the syndrome shows an error in data bit 33, it would really be an error in EMU\_DMW bit 57. You can also XOR the data bit position with "011000". (21h XOR 18h => 39h)

**NOTE:** The user should pre-load the registers with the test values with DIAG\_TRIG=0. After all test values are written, the DIAG\_TRIG should then be set high to validate the diagnostic result.

### 5.6.2.3 ECC Malfunction Test Mode 3: DIAGMODE = 3

There are three inputs to the malfunction detection logic: the resulting syndrome, the original uncorrected data and the final corrected data. See Figure 5-6.

In normal function, the malfunction detection logic will detect an error if the syndrome is 0 and if the data before correction and the data after the correction is not equal or if the syndrome is not 0 and if the data before correction and data after the correction is equal to each other. During diagnostic mode 3 or 4, user supplied values are sent to the malfunction logic. No functional checking is done by the ecc\_malfunction logic while the mode is 3 or 4.

Diagnostic mode 3 is also known as “same data” mode. A diagnostic value can be stored in the ECC checkbit register. The value stored in the 64-bit Raw data register will be supplied to the two inputs of the malfunction comparator logic. If a non-zero value is stored in the Raw ECC checkbit register FRAW\_ECC then the malfunction logic should detect it as an error and set the ECC\_MAL\_ERR bit (ECC malfunction error). There is one ECC\_MAL\_ERR bit for each SECEDED block and they are called ECC1\_MAL\_ERR and ECC0\_MAL\_ERR and are selectable with the DIAG\_ECC\_SEL bit. The DIAG\_TRIG is set to initiate this mode.

The FRAW\_DATAx, FRAW\_ECC and FUNC\_ERR\_ADD will load on an ECC\_MAL\_ERR but will not contain useful information during Diag mode 3.

### 5.6.2.4 ECC Malfunction Test Mode 4: DIAGMODE = 4

This mode is also known as “inverted data” mode. A diagnostic value can be stored in the ECC checkbit register. A value stored in the 64-bit Raw data register and its bit-wise inverted counterpart will be supplied to the two inputs of the malfunction comparator logic. If a zero value is stored in the Raw ECC checkbit register FRAW\_ECC then the malfunction logic should detect it as an error and set the ECC\_MAL\_ERR bit (diagnostic ECC malfunction). See Figure 5-6.

In this mode only, the COM\_MAL\_GOOD bit (Compare Malfunction) is cleared if any one of the 64 XOR gates is malfunctioning. There is one COMx\_MAL\_GOOD bit for each SECEDED blocks and they are called COM1\_MAL\_GOOD and COM0\_MAL\_GOOD. The COMx\_MAL\_GOOD bits go high when entering diagnostic mode 4 and go low and stay low if an error is detected. These bits are only valid in diagnostic mode 4 and outside of this mode the bits are zero.

Set the ECC\_SEL bits before entering mode 4 or enter mode 4 from a nonmode 4 and set the ECC\_SEL bits at the same time. Do not just change the ECC\_SEL bits or the corresponding MAL\_GOOD will not get set because it did not enter mode 4 correctly.

The FRAW\_DATAx, FRAW\_ECC and FUNC\_ERR\_ADD will load on an ECC\_MAL\_ERR but will not contain useful information during Diag mode 4.

Figure 5-6. ECC Malfunction Test Logic

### 5.6.2.5 Address Tag Register Test Mode 5: DIAGMODE = 5

There are four sets of address tag registers. Each set consists of a primary and a duplicate address tag registers. Normally, these registers stores the recently issued CPU addresses during pipeline mode. To detect errors in these registers, the primary and duplicate address tag registers are continuously compared to each other if the buffer is valid. If they are different then an address tag register error event is generated.

These registers are memory mapped. All primary address tag registers are memory mapped to one address and likewise, all duplicate tag registers are mapped to another single address. During diagnostic mode, each individual set can be selected via the 2-bit DIAG\_BUF\_SEL (Diagnostic buffer select) register. User supplied values can be written into the selected set during a diagnostic mode. If different values are written into the primary and the duplicate address tag registers then the ADD\_TAG\_ERR (Address Tag Error) register will be set. This diagnostic mode uses the FRAW\_DATA1 register to supply the alternate address when DIAG\_TRIG is set. The FUNC\_ERR\_ADD will not contain useful information during Diag mode 5. It will also trigger the normal uncorrectable register freeze.

All address tags and buffer valid bits will be set to zero when leaving diag\_mode 5. Going to mode 5 and back out clears the pipeline buffers and is useful for other test modes also. No functional checking is done by the address tag logic while the mode is 5.

---

**NOTE:** The user should pre-load the registers with the test values with DIAG\_TRIG=0. After all test values are written, the DIAG\_TRIG should then be set high to validate the diagnostic result.

---

### 5.6.2.6 ECC Data Correction Diagnostic Mode 7: DIAGMODE = 7

Testing the error correction and ECC logic in the CPU involves corrupting the ECC value returned to the CPU. By inverting one or more bits of the ECC, the CPU will detect errors in a selected data or ECC bit, or in any possible value returned by the ECC.

To set an error for a particular bit use the syndrome, see [Table 5-3](#). For instance if you want to corrupt data bit 62 then put the value 70h into the test register.

The method uses the DATA\_INV\_PAR value in the FPAR\_OVR register to alter the ECC during a slave access cycle. The value in the DATA\_INV\_PAR register will be XORED with the current ECC to give a bad ECC value to the CPU. This only will occur when the DIAG\_MODE is 7, the PAR\_OVR\_KEY is 5, the DIAG\_EN\_KEY in the FDIAGCTRL register is 5 and the access is a slave cycle.

This mode can set the FEDACSTATUS status error bits ECC\_MUL\_ERR or ERR\_ZERO\_FLG but it will not set D\_UNC\_ERR nor D\_COR\_ERR. Also the logic to support the ECCx\_MAL\_ERR and COMx\_MAL\_GOOD bits is not implemented for the CPU path so these bits will not set.

The sequence to do this test would be:

1. Make sure the true DMA module is off.
2. Put 0101b into PAR\_OVR\_KEY and 101b into DAT\_INV\_PAR fields (00005Axxh) of the FPAR\_OVR register (0x7C).
3. Put the desired value in DAT\_INV\_PAR field of FPAR\_OVR register.
4. Put 7 in DIAG\_MODE, and 5 in DIAG\_EN\_KEY of FDIAGCTRL (0x6C).
5. Do a slave access of the desired address.
6. Put 0 in DIAG\_MODE or A in one of the key fields to turn off this test.
7. Check error registers for ECC errors. (0x14, 0x1C, 0x20).
8. Repeat as necessary to test out the ECC.
9. Put 0 in DIAG\_MODE and A in both of the key fields to completely disable this test at the end of the test.
10. Write 5400h to FPAR\_OVR(0x7C) to clear DAT\_INV\_PAR and put 2 into PAR\_OVR\_KEY.

### 5.6.3 Diagnostic Mode Summary

The following table give a summary of the input registers needed for each mode, the possible registers that can change and the possible error bits in FEDACSTATUS that may set.

**Table 5-10. Bus1 Diagnostic Mode Summary**

| DIAG<br>MODE | Name                             | Inputs                                      | Possible Outputs             | Possible Error Bits<br>Set  | Notes             |
|--------------|----------------------------------|---------------------------------------------|------------------------------|-----------------------------|-------------------|
| 1            | ECC Data Correction              |                                             |                              |                             | Not Applicable    |

## 5.6.4 Read Margin

When the bits are programmed or erased, they are checked against a program\_verify or erase\_verify reference level that is far away from the normal read reference point. Over time, bit levels may drift toward the normal read point and if it is too much then a bit will read the wrong value. To counteract this, the bits can be read using different read\_margin reference points to give an early detection of the problem. The bits can then be either re-programmed (most common) or the sector can be erased and reprogrammed.

## 5.7 Control Registers

This section details the Flash module registers, summarized in [Table 5-13](#). A detailed description of each register and its bits is also provided.

The Flash module control registers can only be read and/or written by the CPU while in privileged mode. Each register begins on a word boundary. All registers are 32-bit, 16-bit and 8-bit accessible. The start address of the Flash module is FFF8 7000h.

**Table 5-13. Flash Control Registers**

| Offset     | Acronym        | Register Description                                               | Section                        |

### 5.7.1 Flash Option Control Register (FRDCNTL)

FRDCNTL supports pipeline mode. This register controls flash timings for the main flash banks. For the equivalent register that controls flash timings for the EEPROM Emulation flash bank (bank 7) see [Section 5.7.34](#).

**Figure 5-7. Flash Option Control Register (FRDCNTL) (offset = FFF8 7000h)**

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode; -n = value after reset

**Table 5-14. Flash Option Control Register (FRDCNTL) Field Descriptions**

| Bit   | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                           |
|-------|----------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-12 | Reserved | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                |
| 11-8  | RWAIT    | 0 - Fh | Random/data Read Wait State<br>The random read wait state bits indicate how many wait states are added to a flash read access. In Pipeline mode there is always one wait state even when RWAIT is set to 0.<br><b>Note:</b> The required wait states for each HCLK frequency can be found in the device-specific data sheet.                                                          |
| 7-5   | Reserved | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                |

### 5.7.2 Flash Error Detection and Correction Control Register 1 (FEDACCTRL1)

This register controls ECC event detection for the main flash banks. For the equivalent register that controls ECC event detection for the EEPROM Emulation flash bank (bank 7), see [Section 5.7.35](#).

| 15-0  | FERRCNT  |       | Single Error Correction Count<br>This register contains the number of SEC (single error correction) occurrences. Writing any value to this register resets the count value to zero. The counter resets to zero when it increments to be equal to the single error correction threshold. This register only increments when profiling mode is enabled. This register is not affected by the EOFEN or EZEFEF error control bits in the FEDACCTRL1 register. |

### 5.7.5 Flash Correctable Error Address Register (FCOR\_ERR\_ADD)

This register applies to the main flash banks. For the equivalent register which applies to the EEPROM Emulation flash bank (bank 7) see [Section 5.7.38](#).

The error address is captured during errors when either EOFEN or EZFEN enable bit is set. During error profiling mode when only EPEN is set, the error address is not captured if a correctable error is detected. This register is frozen while either the ERR\_ZERO\_FLG or the ERR\_ONE\_FLG bit is set in the FEDACSTATUS register.

During emulation mode, this address is frozen even when read. By setting the SUSP\_IGNORE bit, (see [Table 5-15](#)) this register can be un-frozen in emulation mode.

This register is not changed with the reset signal and contains unknown data at powerup.

**Figure 5-11. Flash Correctable Error Address Register (FCOR\_ERR\_ADD) (offset = FFF8 7014h)**

LEGEND: R = Read only; -n = value after reset; -u = unchanged value on internal reset, cleared on power up

**Table 5-18. Flash Correctable Error Address Register (FCOR\_ERR\_ADD) Field Descriptions**

| Bit  | Field       | Value | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|------|-------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | COR_ERR_ADD |       | Correctable Error Address<br>COR_ERR_ADD records the CPU logical address of which a correctable error is detected by the ECC logic. This error address is frozen from begin updated until it is read by the CPU. Additional error are blocked until this register is read.                                                                                                                       |
| 2-0  | B_OFF       |       | Byte Offset<br>Since ECC is checked on 64 bit data, when checking main memory or OTP, the address captured is aligned to a 64-bit boundary with address bits[2:0] equal to 0. When reading from the ECC bytes, these bits will indicate the failing address of the ECC location associated with the failure. When reading an ECC byte, the ECC is checked against the 64 data bits they protect. |

### 5.7.6 Flash Correctable Error Position Register (FCOR\_ERR\_POS)

This register applies to the main flash banks. For the equivalent register which applies to the EEPROM Emulation flash bank (bank 7), see [Section 5.7.39](#).

**Note:** The bit error position is only detected during reads of the OTP, the mirrored flash image or the ECC bytes. Single bit errors corrected during reads of the main memory will only capture the failing address, but not the bit position. The bit position is captured during errors when either EOFEN or EZFEN enable bit is set. During error profiling mode when only EPEN is set, the bit position is not captured if a correctable error is detected. This register is frozen while either the ERR\_ZERO\_FLG or the ERR\_ONE\_FLG bit is set in the FEDACSTATUS register.

During emulation mode, this address is frozen even when read. By setting the SUSP\_IGNORE bit, this register can be un-frozen in emulation mode.

This register is not changed with the reset signal and contains unknown data at powerup.

| 7-0   | ERR_POS  |        | The bit address of the single bit error                                                     |

### 5.7.7 Flash Error Detection and Correction Status Register (FEDACSTATUS)

This register applies to the main flash banks. For the equivalent register which applies to the EEPROM Emulation flash bank (bank 7), see [Section 5.7.40](#).

All these error status bits can be cleared by writing a one to the bit. Writing a zero has no effect.

The correctable errors in bits 2:0, and FSM\_DONE bit 24, must be cleared before the end of their error event service routine or else the error event will re-issue.

Field Descriptions (continued)**

| Bit   | Field       | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------|-------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 17    | B2_UNC_ERR  | 0<br>1 | <p>Bus 2 uncorrectable error</p> <p>No bus 2 uncorrectable errors were detected</p> <p>A bus 2 uncorrectable error was detected</p> <p>Two or more bits in the data, or ECC field; or a single bit error in the address field have been found in error. Address bit errors are considered an uncorrectable error. The FUNC_ERR_ADD register should contain the Bus2 error location. This error will generate an ESM group 3 channel 7 event.</p>                                                                                                                                                                                                                                                                           |
| 16    | B2_COR_ERR  | 0<br>1 | <p>Bus 2 Correctable Error</p> <p>No bus2 correctable error was detected</p> <p>A bus 2 correctable error was detected</p> <p>One bit in the data, or ECC field has been found in error. Either the ERR_ONE_FLAG or ERR_ZERO_FLAG should be set in this register along with this bit. The FCOR_ERR_ADD register should contain the error address, and the FCOR_ERR_POS register should contain the failing bit position. This error will generate an ESM group 1 channel 6 event.</p>                                                                                                                                                                                                                                      |
| 15-13 | Reserved    | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 12    | D_UNC_ERR   |        | <p>Diagnostic Uncorrectable Error</p> <p>This bit sets when diagnostic mode 1 discovers a multi-bit error using the ECC. This means two or more bits in the data, address or ECC field have been found in error. The ECC is capable of correcting a single bit error and this would show up in bit 3 D_COR_ERR. The ECC can always detect two bit errors. Three or more bit errors may escape detection with the ECC. This bit also may set during other uncorrectable errors and during the diagnostic mode like address tag errors and ECC malfunctions.</p>                                                                                                                                                             |
| 11    | ADD_TAG_ERR | 0<br>1 | <p>Address Tag Register Error Flag</p> <p>Address Tag Register Error not detected</p> <p>Address Tag Register Error detected.</p> <p>This bit is set if the primary address tag has a hit but the duplicate address tag does not match the primary address tag. This bit is functional only when pipeline mode is enabled. This error will create an ESM group 3 channel 7 event.</p>                                                                                                                                                                                                                                                                                                                                      |
| 10    | ADD_PAR_ERR | 0<br>1 | <p>Address Parity Error Flag</p> <p>No address parity error was detected.</p> <p>A parity error was detected on the incoming address bus.</p> <p>The full 32 bit address will be stored in FUNC_ERR_ADD register. This error will create an ESM group 2 channel 4 event.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 9     | Reserved    | 0      | Read returns 0. ### 5.7.8 Flash Un-Correctable Error Address Register (FUNC\_ERR\_ADD)

This register applies to ECC event detection for the main flash banks. For the equivalent register which applies to the EEPROM Emulation flash bank (bank 7), see [Section 5.7.41](#).

During emulation mode, this address is frozen even when read. By setting the SUSP\_IGNORE bit, (see [Table 5-15](#)) this register can be un-frozen in emulation mode.

This register is not changed with the reset signal and contains unknown data at powerup.

**Figure 5-14. Flash Un-Correctable Error Address Register (FUNC\_ERR\_ADD) (offset = FFF8 7020h)**

LEGEND: R = Read only; -n = value after reset; -u = unchanged value on internal reset, cleared on power up

**Table 5-21. Flash Un-Correctable Error Address Register (FUNC\_ERR\_ADD) Field Descriptions**

| Bit  | Field       | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|-------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | UNC_ERR_ADD |       | Un-correctable Error Address<br><br>UNC_ERR_ADD records the CPU logical address of which an un-correctable error is detected by the ECC logic in the CPU. The UNC_ERR_ADD also captures the error address when a address bus parity mismatch is detected. This error address is frozen from begin updated until it is read by the CPU. Additional error are blocked until this register is read.<br><br>This register captures the full 32 bit incoming address when there is a bus parity error. It only captures address of 22:3 for multiple bit ECC errors. Address parity errors take priority over other errors that happen in the same cycle. |
| 2-0  | B_OFF       |       | Byte offset<br><br>Since ECC is checked on 64 bit data, when checking main memory or OTP, the address captured is aligned to a 64-bit boundary with address bits[2:0] equal to 0. When reading from the ECC bytes, these bits will indicate the failing address of the ECC location associated with the failure. When reading an ECC byte, the ECC is checked against the 64 data bits they protect.                                                                                                                                                                                                                                                 |

### 5.7.9 Flash Error Detection and Correction Sector Disable Register (FEDACSDIS)

This register is used to disable the SECDED function for one or two sectors from the EEPROM Emulation flash (bank 7). An additional two sectors can have SECDED disabled by the use of the FEDACSDIS2 register (see [Section 5.7.31](#)).

**Figure 5-15. Flash Error Detection and Correction Sector Disable Register (FEDACSDIS)

### 5.7.13 Flash Bank Sector Enable Register (FBSE)

FBSE provides one enable bit per sector for up to 16 sectors per bank. Each bank in the Flash module has one FBSE register. The bank is selected via the BANK[2:0] bits of the FMAC register (see [Section 5.7.20](#)). As only one bank at a time can be selected by FMAC, only the register for the bank selected appears at this address.

**Table 5-38. EEPROM Emulation Address Register (FEMU\_ADDR) Field Descriptions**

| Bit   | Field    | Value     | Description                                                                                                                                                                                                                                                                                                                                                         |
|-------|----------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-22 | Reserved | 0         | Reserved; writes have no affect. It is not necessary to mask these upper ten bits when writing the address of bank 7 locations (0xF002xxxx), however these bits are not used in calculating the ECC value and will read back as zero.                                                                                                                               |
| 21-3  | EMU_ADDR | 0-7 FFFFh | EEPROM Emulation Address<br>This register contains the upper 19 bits of the 83-bit data used to calculate the ECC. When this register is written, the corresponding ECC word is updated in FEMU_ECC register.<br>This register is also used in the diagnostic modes 1 and 2. In these modes, this register supplies the address bits 21:3 for checking the SECDDED. |
| 2-0   | Reserved | 0         | Reserved; writes have no affect. The lower three bits of the CPU address are not used in the ECC calculation to align the data on a 64-bit boundary. These bits will read back as zero.                                                                                                                                                                             |

### 5.7.26 Diagnostic Control Register (FDIAGCTRL)

Set the DIAG\_MODE and the DIAG\_EN\_KEY first before setting up the other registers to block the other registers from causing a false error. The final write should set the DIAG\_TRIG register to activate the test. Running out of ram will prevent problems with the diagnostic test corrupting the flash access in some of the modes.

This register is present only when SIL3\_config = 1, otherwise, this is an unimplemented location. Reads will return zeros; writes do nothing but no address error will be generated.

| 24    | DIAG_TRIG    |                                          | Diagnostic Trigger<br>Diagnostic trigger is the final qualifier for the diagnostic result. After setting all the other diagnostic register values, the DIAG_TRIG is set to 1. This will activate the diagnostic logic for one access and then automatically clear the DIAG_TRIG value. DIAG_EN_KEY and DIAGMODE must be set at least one cycle before setting DIAG_TRIG.<br>This bit always reads as zero.   |

**Table 5-40. Uncorrected Raw Data High Register (FRAW\_DATAH) Field Descriptions**

| Bit  | Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | RAW_DATA [63:32] | <p><b>Uncorrected Raw Data</b></p> <p>This register contains the upper 32 bits of the 64-bit uncorrected raw data passed into the SECDEC. This register captures the uncorrected data passed when either an 'error on one fail' or an 'error on zero fail' or a multi-bit error is detected. The register is frozen until the respective error status flag in FEDACSTATUS is cleared by CPU. This register does not update if the error was found while using pipeline buffer data.</p> <p>An ECC malfunction error will not save the correct data into the FRAW_x registers but it will freeze the register from further updates.</p> <p>If both SECDEDs detect any one of the correctable errors at the same time then only the uncorrected data passed into SECDED0 is captured. The corresponding error address is also saved into FCOR_ERR_ADD register.</p> <p>This register is used in the pipeline buffer parity diagnostic mode (DIAG_MODE=6). This diagnostic mode checks the logic that compares the stored pipeline buffer parity against the stored pipeline buffer data. Diag mode 6 will replace the stored pipeline buffer data with FRAW_DATAH and FRAWDATAL. It will also replace the stored pipeline parity with FRAW_ECC. When the DIAG_TRIG is set it uses these replacement registers to exercise the compare logic to see if it functions correctly.</p> <p>This register is loaded with the current read data when the ECC Malfunction logic detects an error. This register will change during an ECCx_MAL_ERR error in diagnostic mode 3 or 4 but it will contain no useful information.</p> <p>This register can also be updated by the FMC, when not frozen, by other diagnostic modes that trigger an ECC error.</p> <p><b>NOTE:</b> Raw Data and Raw ECC registers can be loaded with diagnostic values only in diagnostic modes 1 through 6 with DIAG_EN_KEY=0101. These modes must be set for at least one clock cycle before writing to any FRAW* register.</p> |

## 5.7.28 Uncorrected Raw Data Low Register (FRAW\_DATAL)

| 8    | PIPE BUF     |       | <p>Error came from pipeline buffer hit</p> <p>When this bit is a one, latest error came from a pipeline buffer hit and the FRAW_DATH, FRAW_DATL, and RAW_ECC fields will not contain information that matches the error address nor error status bits. This bit is cleared when the RAW_ECC field is updated with new valid information or by writing a one to this bit.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 7-0  | RAW_ECC[7:0] |       | <p>Uncorrected Raw ECC</p> <p>This register contains the uncorrected ECC data passed into the SECDEC. This register captures the uncorrected data passed when either an error on one fail or error on zero fail is detected. The register is frozen until the respective error status flag is cleared by CPU. This register does not update if the error was found while using pipeline buffer data.</p> <p>In the event of a non-diagnostic ECC malfunction error event, the FRAW_x registers are frozen but will contain useless data. They will be unfrozen when the ECC_MAL_ERR flag bit is cleared..</p> <p>Secondly, this register is used in the pipeline buffer parity diagnostic mode (DIAG_MODE=6). Here it replaces the pipeline parity data with the FRAW_ECC value and the buffer data is replaced with the data in the FRAW_DATAH and FRAW_DATAH registers.</p> <p>Thirdly, this register is loaded with the current ECC data when the ECC Malfunction logic detects an error. The register changes during an ECCx_MAL_ERR error in diagnostic mode 3 or 4, but it will contain no useful information.</p> <p><b>NOTE:</b> Raw Data and Raw ECC registers can loaded with diagnostic values only in a used diagnostic mode with DIAG_EN_KEY=0101. This mode must be set for at least one clock cycle before writing to any FRAW* register.</p> |

### 5.7.30 Parity Override Register (FPAR\_OVR)

This register is present only when SIL3\_config=1, Otherwise this is unimplemented location. Reads will return zeros; writes do nothing and no address error will be generated.

**Figure 5-36. Parity Override Register (FPAR\_OVR) (offset = FFF8 707Ch)**

| 16    | BNK_INV_PAR |       | Buffer Invert Parity<br>When this value is one and PAR_OVR_KEY is '101' then the current system parity signal SYS_ODD_PARITY is inverted when doing bank parity calculations. This will generate parity errors and cause interrupt signals to be generated. When zero, the SYS_ODD_PARITY value is used. This bit is only implemented for parity configurations and is reserved for ECC devices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 15-12 | BUS_PAR_DIS |       | Disable Bus Parity<br>When this value is "1010", the address bus parity error and buffer parity error are disabled and no checking is done and no events are generated. Any other value will enable the parity checking on the Address bus and read data bus. The read data parity is never disabled from this module.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 11-9  | PAR_OVR_KEY |       | When this value is "101", the selected ADD_INV_PAR and DAT_INV_PAR fields will become active. Any other value will cause the module to use the global system parity bit in the system register DEVCR1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 8     | ADD_INV_PAR |       | Address Odd Parity<br>This bit is active only when PAR_OVR_KEY = '101'. When ADD_INV_PAR is one, the incoming address bus will invert the system signal SYS_ODD_PARITY for parity calculations. This will cause parity errors and generate interrupt error signals. When zero it will use the SYS_ODD_PARITY value. This bit is set to the SYS_ODD_PAR signal value on reset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 7-0   | DAT_INV_PAR |       | Data Odd Parity<br>This byte is active only when PAR_OVR_KEY = '101'. When a DATA_INV_PAR bit is one, the output read data will invert the system signal SYS_ODD_PARITY for parity calculations. This will cause parity errors and generate interrupt signals. When zero it will use the SYS_ODD_PARITY value. This byte can support up to a 64 bit data bus but when the device has a 32 bit bus, bits 7:4 are reserved.<br>Bit 0 affects read bus bits 7:0, Bit 1 affects read bus bits 15:8 and so on. Each active bit of this field is set to the SYS_ODD_PAR signal value on reset.<br>The DAT_INV_PAR is used in the parity for the pipeline buffer logic and for the read data bus to the CPU.<br>When the ECC logic is in the CPU (CONF_TYPE = 5) and SIL3 is active, this field becomes the ECC corrupting value for SIL3 diagnostic mode 7. (Starting with version 1.0.0.0)<br>In diagnostic mode 7 the FPAR_OVR should be set to 00005Axxh to allow writes to the DAT_INV_PAR field. This field should be written before entering diagnostic mode 7. |

### 5.7.31 Flash Error Detection and Correction Sector Disable Register (FEDACSDIS2)

This register is used to disable the SECDED function for one or two sectors from the EEPROM Emulation flash (bank 7). An additional two sectors can have SECDED disabled by the use of the FEDACSDIS register. see [Section 5.7.9](#).

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode; -n = value after reset

This is a banked register. A separate register is implemented for each bank, but they all occupy the same address. The correct bank must be selected in the FMAC register before reading or writing this register. See [Section 5.7.20](#).

**Table 5-46. FSM Register Write Enable (FSM\_WR\_ENA) Field Descriptions**

| Bit   | Field             | Value | Description                                                                                                                                                                                                                        |
|-------|-------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | SECT_ERASED[16:0] |       | Sectors Erased<br>There is one bit for each sector. Bit 16 corresponds to sector 0, bit 17 corresponds to sector 1, and so on. After bank erase, the bit corresponding to each sector which is erased will be changed from 0 to 1. |
|       |                   | 0     | During bank erase, each sector will be erased.                                                                                                                                                                                     |
|       |                   | 1     | Each sector will not be erased.                                                                                                                                                                                                    |
| 15-0  | Reserved          | 0     | These bits are used by the state machine during bank erase. Do not write to these bits.                                                                                                                                            |

| 31-16 | Reserved  | 0       | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 15-0  | EE_ERRCNT | 0-FFFFh | Single Error Correction Count<br><br>This register contains the number of SEC (single error correction) occurrences. Writing any value to this register resets the count value to zero. The counter resets to zero when it increments to be equal to the single error correction threshold. This register only increments when profiling mode is enabled. This register is not affected by the EE_ZERO_EN or EE_ONE_EN error control bits in the EE_CTRL1 register. |

### 5.7.38 EEPROM Emulation Correctable Error Address Register (EE\_COR\_ERR\_ADD)

During emulation mode, this address is frozen even when read. By setting the SUSP\_IGNR bit, (see [Table 5-15](#)) this register can be un-frozen in emulation mode.

This register is not changed with the reset signal and contains unknown data at powerup.

**Figure 5-44. EEPROM Emulation Correctable Error Address Register (EE\_COR\_ERR\_ADD)  
(offset = FFF8 7314h)**

LEGEND: R = Read only; -n = value after reset; -u = unchanged value on internal reset, cleared on power up

## 6.1 Overview

The Hercules™ family of microcontrollers are based on the ARM® Cortex-R4F™ processor. This CPU has two tightly-coupled memory interfaces – ATCM and BTCM, which are used to interface to the program and data memories, respectively. The Hercules MCUs use the ATCM interface for the main flash memory and the BTCM interface for the CPU data RAM.

### 6.1.1 B0TCM and B1TCM Connection Diagram

The BTCM interface is further divided into two parts – B0TCM and B1TCM, which are both used to interface to actual RAM banks as shown in [Figure 6-1](#).

**Figure 6-1. TCRAM Module Connections**

### 6.1.2 Main Features

The main features of the tightly-coupled RAM interface module are:

- Controls read/write accesses to the data RAM
- Decodes addresses within the memory region allocated for the RAM
- Supports read and write accesses in 64-bit, 32-bit, 16-bit or 8-bit access sizes
  - Does not support bit-wise operations
- Safety Features:
  - Support for Cortex-R4F CPU's Built-In Single-Error-Correction Double-Error-Detection (SECDED) Logic
    - Uses the CPU's Event bus and maintains the SECDED status in memory-mapped registers
    - Captures the number of occurrences of single-bit or multi-bit errors as well as the RAM address that has the fault
    - Generates signals for indicating single-bit and multi-bit errors to the Error Signaling Module (ESM)
  - Support for Cortex-R4F CPU's Parity Protection Logic for BTCM Address Bus and Control Signals
    - Uses the CPU's TCM Address Parity Scheme and indicates an address bus parity error to the ESM

- Redundant Address Decode Scheme
  - Checks the decoding of CPU address lines and generation of correct memory selects for the RAM banks
  - Also supports checking of the redundant address decode comparators themselves
- Supports auto-initialization of the CPU data RAM banks
- Supports the RAM Trace Port (RTP) Interface
  - Traces out all RAM read and write accesses to the RTP module

## 6.2 RAM Memory Map

The ARM Cortex-R4F CPU allows up to 8MB to be accessed through the BTCM interface. The Hercules family of microcontrollers support up to 256KB RAM on the BTCM interface. Check the specific part's datasheet to identify the actual amount of TCRAM supported on the part. This RAM is protected by ECC allowing the CPU to correct any single-bit errors and detect double-bit errors within a 64-bit value. The error correction codes (ECC) are stored in the RAM memory space as well. The memory map for the TCRAM and the corresponding ECC space is shown in [Figure 6-2](#). Any access to an unimplemented TCRAM location results in an error response from the TCRAM module.

**Figure 6-2. RAM Memory Map**

Each RAM data word is 64 bits wide. These 64 bits are divided into 32 bits per RAM bank as shown in [Figure 6-1](#). The 8 bits of ECC are also divided into 4 bits per RAM bank.

For every 64-bit read from the RAM, an 8-bit ECC is also read by the CPU on its ECC bus. Similarly, for every 64-bit write to the RAM, the CPU also writes an 8-bit ECC using the same ECC bus.

**NOTE: Read-Modify-Write Requirement for Writes to RAM:** The TCRAM interface module supports 64-bit, 32-bit, 16-bit or 8-bit writes to the RAM. However the ECC is calculated by the CPU for 64-bit values only. For any write access smaller than 64 bits, it is necessary to force the CPU to perform a 64-bit read-modify-write operation in order to ensure that the correct ECC is also written. This can be done by setting the bit 1: BTCMRMW of c15, the Secondary Auxiliary Control Register of the CPU. **This bit is already set by default.**

The ECC memory can also be directly accessed via memory-mapped offset addresses starting from 4MB, as shown in . A read from the ECC space results in the 8-bit ECC value appearing on each byte of the 64-bit CPU data. The ECC memory can only be written to as a 64-bit access. The write to the ECC space must also first be enabled via the RAM Control Register (RAMCTRL).

Accesses to the ECC space are not traced out to the RAM Trace Port (RTP).

---

**NOTE: No ECC Error Generated for Accesses to ECC Memory:** A read from the ECC space send the ECC value on both the 64-bit TCM read data bus as well as the 8-bit ECC bus. This could result in the detection of a multi-bit error by the SECDED logic inside the CPU. The TCRAM interface module ignores the ECC error indicated by the CPU for the access to the ECC space.

---

## 6.3 Safety Features

The TCRAM interface module incorporates some features that are designed specifically with safety considerations. These are described in the following sections.

### 6.3.1 Support for Cortex-R4F CPU's Single-Error-Correction Double-Error-Detection (SECDED)

The TCRAM interface module monitors the CPU's event bus. The CPU's event bus signals single-bit or multi-bit errors for B0TCM as well as B1TCM separately. These signals are monitored by the TCRAM modules for each of these interfaces.

#### TCRAM Interface Module Features dedicated for SECDED Support:

- Dedicated single-bit error counter
  - This counter is stored in a memory-mapped register called [RAMOCCUR](#)
  - RAMOCCUR is used to count the single-bit errors corrected by the CPU's SECDED logic
  - The TCRAM interface module allows the application to generate an interrupt via the [RAMINTCTRL](#) register when the number of single-bit errors corrected by the CPU exceeds a programmable threshold, [RAMTHRESHOLD](#)
- RAM Error Status Register
  - The errors detected by the TCRAM interface module as well as those indicated by the CPU are flagged in the [RAMERRSTATUS](#) register
  - There are separate bits to indicate single-bit error, double-bit error, address decode failure, address compare logic failure, read-address parity failure, and write-address parity failure
- ECC Error Address Capture
  - Separate registers to hold the address on which a single-bit error is detected ( [RAMSERRADDR](#)) or a double-bit error is detected ( [RAMUERRADDR](#))
  - The RAMSERRADDR register is only updated when the RAMTHRESHOLD value is set to 1
  - Both the RAMSERRADDR and RAMUERRADDR capture the 64-bit-aligned address for the access to the TCRAM as an offset from the base address of the TCRAM (0x08000000 by default)

---

**NOTE: Cortex-R4F CPU Event Bus Signaling Not Enabled By Default:** Upon power-up and after a CPU reset, the event signaling mechanism inside the Cortex-R4F CPU is disabled. This feature must be enabled by setting the Export (X-bit) of the Performance Monitoring and Control Register (PMNC) in the CPU. The TCRAM interface module can only capture the single-bit or double-bit ECC error occurrences once the CPU's event signaling mechanism is enabled.

---

### 6.3.2 Support for Cortex-R4F CPU's Address and Control Bus Parity Checking

The Cortex-R4F CPU calculates a single parity-bit for the TCRAM address and control signals. The TCRAM interface module also computes this parity bit based on the CPU's address bus and control signals. The computed parity bit is compared against the parity bit received from the CPU. A mismatch is signaled as an Address Parity Failure to the Error Signaling Module (ESM) group2 channel 10 or 12. There is a separate address parity failure error channel for B0TCM and B1TCM.

The 64-bit TCRAM address which fails the parity check is captured in the [RAMPERRADDR](#) register as an offset from the base address of the TCRAM (0x08000000 by default). The TCRAM interface module also indicates the type of access, read or write, that failed the parity check. This is indicated by the RADDR PAR FAIL or the WADDR PAR FAIL status flags in the [RAMERRSTATUS](#) register.

The RAMERRSTATUS and RAMPERRADDR registers must be cleared by the application in order for the TCRAM interface module to continue capturing subsequent errors and error addresses.

The parity scheme used for the described parity checking mechanism is defined by the global system parity selection. This can be configured using the DEVPARSEL field of the DEVCR1 control register in the system module. This device-wide parity scheme can be overridden inside the TCRAM interface module by configuring the Address Parity Override field in the [RAMCTRL](#) register.

---

**NOTE: No Change Of Parity Scheme On-The-Fly:** The TCRAM interface module does not support on-the-fly change to the parity scheme being used for checking the CPU address bus and control bus. The application must ensure that the parity polarity (odd or even) is not changed while there is an ongoing access to the TCRAM.

---

### 6.3.3 Redundant Address Decode

The TCRAM interface module generates the memory selects for each of the TCRAM banks as well as the ECC memory based on the CPU address. The logic to generate these memory selects is duplicated and the outputs compared to detect any address decode errors. A mismatch is indicated as an Address Error to the Error Signaling Module (ESM), one signal for B0TCM and one for B1TCM. The TCRAM or ECC address that caused the fault is captured in the [RAMUERRADDR](#) register. This is a 64-bit-aligned address is stored as an offset from the base of the TCRAM or ECC memory.

As described earlier, each individual physical RAM bank is 36 bits wide. Each RAM bank contributes 32 bits of data and 4 bits of ECC when the bus master performs a 64-bit read from the TCRAM. Each TCRAM bank receives a memory select and the address from the TCRAM interface module. Any difference between the address and the memory selects results in wrong data and ECC pair being sent to the CPU. The CPU's SECDED block will detect this data error.

The TCRAM interface module also supports a mechanism to test the operation of the redundant address decode logic and the compare logic. This testing is supported by providing a test stimulus, and can be triggered by the application by configuring the [RAMTEST](#) register. The address of any error identified during testing of the redundant address decode and compare logic is not captured in the RAMUERRADDR register.

---

**NOTE: Address decode checking when in compare logic test mode:** When the address decode and compare logic test mode is enabled, the redundant address decode and compare logic is not available for checking the proper generation of the memory selects for the TCRAM and ECC memory.

---

## 6.4 TCRAM Auto-Initialization

The RAM memory can be initialized by using the dedicated auto-initialization hardware. The TCRAM Module initializes the entire memory when the auto-init is enabled for the RAM. All RAM data memory is initialized to zeros and the ECC memory is initialized to the correct ECC value for zeros, that is, 0Ch.

## 6.5 Trace Module Support

The TCRAM Module traces out the following signals to the RAM Trace Port (RTP) module, thereby providing RAM dataport trace capability.

- 18-bit address line
- 64-bit data bus
- Byte strobe information
- Current access master identification number
- Access type: Opcode or data fetch
- Read or Write access

No data is traced for an access to ECC memory.

## 6.6 Emulation / Debug Mode Behavior

The following describes the behavior of the TCRAM Module when in debug mode:

- The [RAMOCCUR](#) register continues to count the single-bit error corrections performed by the Cortex-R4F CPU's SECEDED logic.
- No single-bit error interrupt is generated nor is any single-bit error address captured even when the RAMOCCUR counter reaches the programmed single-bit error correction threshold.
- No uncorrectable error interrupt is generated nor is any double-bit error address captured.
- No address parity error interrupt is generated nor is any parity error address captured.
- The [RAMUERRADDR](#) register is not cleared by a read in debug mode.
  - That is, if a double-bit error address is captured and is not read by the CPU before entering debug mode, then it remains frozen during debug mode even if it is read.
- The [RAMPERRADDR](#) register is not cleared by a read in debug mode.

## 6.7 Control and Status Registers

The TCRAM Module registers are accessed through the system module registers' space in the Cortex-R4F CPU's memory map. All registers are 32-bit wide and are located on a 32-bit boundary. Reads and writes to registers are supported in 8-, 16-, and 32-bit accesses. The base address for the control registers is FFFF F800h and FFFF F900h for even and odd RAM ECC.

**Table 6-1. TCRAM Module Control and Status Register Map**

| Offset | Acronym        | Register Description                                        | Section                        |

A write access to the ECC memory is allowed only when the ECC WR EN bit is set to 1. If this bit is cleared, then any writes to ECC memory are ignored.<br>Note: Reads are allowed from the ECC memory regardless of the state of the ECC WR EN.<br>ECC memory writes are disabled.<br>ECC memory writes are enabled.          |
| 7-4   | Reserved             | 0                | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                       |

**Table 6-2. TCRAM Module Control Register (RAMCTRL) Field Descriptions (continued)**

| Bit | Field         | Value      | Description                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----|---------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3-0 | ECC DETECT EN |            | ECC Detect Enable. This is a 4-bit key to enable the ECC detection feature in the TCRAM Module. If this field is set to any value other than 5h, then the TCRAM Module starts monitoring the TCM event bus and generates the corresponding error status flags. The error status updates are done only when the ECC DETECT EN field is not 5h. The ECC detection is enabled by default as the ECC DETECT EN default value is Ah. |
|     |               | 5h         | ECC detection is disabled.                                                                                                                                                                                                                                                                                                                                                                                                      |
|     |               | All Others | ECC detection is enabled.                                                                                                                                                                                                                                                                                                                                                                                                       |

### 6.7.2 TCRAM Module Single-Bit Error Correction Threshold Register (RAMTHRESHOLD)

The RAMTHRESHOLD register, shown in [Figure 6-4](#) and described in [Table 6-3](#), allows the application to configure the number of single-bit error corrections by the SECEDED logic inside the Cortex-R4F CPU before generating a single-bit error interrupt.

**Figure 6-4. TCRAM Module Single-Bit Error Correction Threshold Register (RAMTHRESHOLD)  
[offset = 04h]**

| Bit   | Field     | Value | Description                                                                                                                                                                                                                                                                                                                                                  |
|-------|-----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved  | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                       |
| 15-0  | THRESHOLD |       | Single-bit Error Threshold Count. This field contains the threshold value for the Single-bit Error Correction (SEC) occurrences before the single-bit error interrupt is generated. If this threshold is set to 1 then all single-bit error addresses are captured. To enable the error occurrence detection, the threshold must be set to a non-zero value. |

### 6.7.3 TCRAM Module Single-Bit Error Occurrences Counter Register (RAMOCCUR)

The RAMOCCUR register, shown in [Figure 6-5](#) and described in [Table 6-4](#), indicates the number of single-bit error corrections performed by the SEC logic inside the Cortex-R4F CPU.

**Figure 6-5. TCRAM Module Single-Bit Error Occurrences Counter Register (RAMOCCUR) [offset = 08h]**

| 31-16 | Reserved                 | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 15-0  | SINGLE ERROR OCCURRENCES |       | <p>Single-bit Error Correction Occurrences. This 16-bit counter contains the number of single-bit error occurrences. RAMOCCUR is reset to zero when it becomes equal to the THRESHOLD value set in the RAMTHRESHOLD register. The application must clear the RAMOCCUR register by writing 0x0 before setting the THRESHOLD value. If the RAMOCCUR value is already higher than the programmed THRESHOLD value then the counter increments and wraps around (overflow) to zero.</p> <p><b>Note:</b> If the application tries to clear the RAMOCCUR register at the same time as the TCRAM Module tried to update it, then the TCRAM Module takes priority.</p> <p><b>Note:</b> When the RAMTHRESHOLD register is set to 1, then the RAMOCCUR register must be cleared whenever a single-bit error correction occurs in order to count subsequent single-bit error corrections.</p> |

### 6.7.4 TCRAM Module Interrupt Control Register (RAMINTCTRL)

The RAMINTCTRL register, shown in [Figure 6-6](#) and described in [Table 6-5](#), enables the generation of an interrupt to the CPU whenever the number of single-bit error corrections (RAMOCCUR) reaches the programmed threshold (RAMTHRESHOLD).

**Figure 6-6. TCRAM Module Interrupt Control Register (RAMINTCTRL) [offset = 0Ch]**

| 5     | DERR                 |       | This bit indicates a multi-bit error detected by the Cortex-R4F SECCED logic.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 4     | ADDR COMP LOGIC FAIL |       | Address decode logic element failed. This bit indicates that the redundant address decode logic test scheme has detected that a compare element has malfunctioned during the testing of the logic. This bit has to be cleared by writing 1 to it in order to enable the capture of uncorrectable error address for subsequent failures. This bit has to be in a cleared state for generation of a new uncorrectable error interrupt. This bit only gets set in the test mode, and has no relevance in functional mode. |
| 3     | Reserved             | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 2     | ADDR DEC FAIL        |       | Address decode failed. This bit indicates that an address error interrupt was generated by the redundant address decode and compare logic due to a functional failure. This bit must be cleared by writing 1 to it in order to enable the capture of uncorrectable error address for subsequent failures. This bit has to be in a cleared state for generation of a new address error interrupt.                                                                                                                       |
| 1     | Reserved             | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 0     | SERR                 |       | Single Error Status. This bit indicates that the single-bit error threshold has been reached. This bit is set even if the single-bit error threshold interrupt is disabled. This bit must be cleared by writing 1 to it in order to clear the interrupt request and to enable subsequent single-bit error interrupt generation.                                                                                                                                                                                        |

**NOTE:** For equality test:

- If the comparator matches (no true silicon fail), there is no status bit set for ADDR COMP LOGIC FAIL or ADDR DEC FAIL.
- If there is true silicon malfunction, ADDR COMP LOGIC FAIL & ADDR DEC FAIL will be set, no UERRADDRESS is captured.

For inequality test, the compare vector will not match since non-inverted and inverted values of the same test vector are fed to the comparator:

- If there is no silicon malfunction on any of the comparator bits, then only ADDR DEC FAIL will be set. This is chosen so that we can ensure the functional ADDR DEC FAIL status bit data path can be tested.
- If there is a silicon malfunction on any of the comparator bits, then, ADDR COMP LOGIC FAIL & ADDR COMP LOGIC FAIL will be set, no UERRADDRESS is captured.

### 6.7.6 TCRAM Module Single-Bit Error Address Register (RAMSERRADDR)

The RAMSERRADDR register, shown in [Figure 6-8](#) and described in [Table 6-7](#), captures the address for which the Cortex-R4F CPU detected a single-bit error.

**Figure 6-8. TCRAM Module Single-Bit Error Address Register (RAMSERRADDR) [offset = 14h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 6-7. TCRAM Module Single-Bit Error Address Register (RAMSERRADDR) Field Descriptions**

| Bit   | Field                | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| 22-3  | UNCORRECTABLE ERROR ADDRESS |       | <p>This register captures the address for which there was an uncorrectable error or an address parity error.</p> <p>The uncorrectable error is indicated by the Cortex-R4F CPU's SECEDED logic and the address parity error is indicated by the TCRAM Module's redundant address decode and compare logic.</p> <p>For the SECEDED multi-bit or double-bit uncorrectable error this register stores the bits 17-3 of the TCM access address. The lower 3 bits 2-0 are always read as zeros to indicate that the latched address is a double-word address. The address bits 31-18 are read as zeros. This is a 64-bit-aligned address is stored as an offset from the base of the TCRAM or ECC memory.</p> <p>For a redundant address decode and compare logic error this register stores the complete TCM access address rounded to a double-word boundary (bits 22-3). This error is also indicated by the ADDR DEC FAIL status flag in the RAMERRSTATUS register. No error address is stored as a result of a redundant address logic test.</p> <p>The register has to be read-cleared to enable further error address captures. Reading the register does not clear its contents but enables the register to be updated with an uncorrectable error address.</p> <p>This register can only be reset by asserting power-on reset, and holds the last error address even after a system reset.</p> |

| 8    | TRIGGER     |                  | Test Trigger. This is an auto reset test trigger used to test the redundant address decode and compare logic. A redundant address decode test is executed when test mode is enabled and the test trigger is applied by writing a 1 to this bit. The trigger is valid only if test is enabled and the correct mode is configured in the TEST MODE field, and the RAMERRSTATUS and RAMUERRADDR registers are in the cleared state.                                                                                                                                                                                                                                                                                                                                 |
| 7-6  | TEST MODE   |                  | Test Mode. This field selects either equality or inequality testing schemes.<br><br>If TEST MODE is set to 2h, equality check is done. The test stimulus stored in ADDRTEST_VECT register is fed directly to both the channels of the comparator. If the XOR of these two inputs is <b>not zero</b> then UERR interrupt is generated and ADDR COMP LOGIC FAIL flag is set in RAMERRSTATUS register.<br><br>If TEST MODE is set to 1h, inequality check is done. The test stimulus stored in ADDRTEST_VECT register is inverted and fed into one channel and the non-inverted vector is fed into the other channel. If the XOR of these inputs is <b>zero</b> then the UERR interrupt is generated and ADDR COMP LOGIC FAIL flag is set in RAMERRSTATUS register. |
| 5-4  | Reserved    | 0                | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 3-0  | TEST ENABLE | Ah<br>All Others | Test Enable. This is a 4-bit key to enable the redundant address decode and compare logic test scheme. If the test scheme is enabled then the compare logic uses the test vector inputs from the ADDRTEST_VECT register. The functional path comparison is disabled when test mode is enabled.<br><br>Test mode is enabled.<br><br>Test mode is disabled.                                                                                                                                                                                                                                                                                                                                                                                                        |

**NOTE:** For equality test:

- If the comparator matches (no true silicon fail), there is no status bit set for ADDR COMP LOGIC FAIL or ADDR DEC FAIL.
- If there is true silicon malfunction, ADDR COMP LOGIC FAIL & ADDR DEC FAIL will be set, no UERRADDRESS is captured.

For inequality test, the compare vector will not match since non-inverted and inverted values of the same test vector are fed to the comparator:

- If there is no silicon malfunction on any of the comparator bits, then only ADDR DEC FAIL will be set. This is chosen so that we can ensure the functional ADDR DEC FAIL status bit data path can be tested.
- If there is a silicon malfunction on any of the comparator bits, then, ADDR COMP LOGIC FAIL & ADDR COMP LOGIC FAIL will be set, no UERRADDRESS is captured.

### 6.7.9 TCRAM Module Test Mode Vector Register (RAMADDRDECVECT)

The RAMADDRDECVECT register, shown in [Figure 6-11](#) and described in [Table 6-10](#), is used for testing the redundant address decode and compare logic of the TCRAM Module.

**Figure 6-11. TCRAM Module Test Mode Vector Register (RAMADDRDECVECT) [offset = 38h]**

**Table 6-10. TCRAM Module Test Mode Vector Register (RAMADDRDEVECT) Field Descriptions**

| Bit   | Field           | Value | Description                                                                                                                                                                                          |
|-------|-----------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-27 | Reserved        | 0     | Read returns 0. Writes have no effect.                                                                                                                                                               |
| 26    | ECC SELECT      |       | ECC Select. This bit is used to store the ECC select value for the redundant address decode and compare logic. The stored value is passed as test stimulus for the built-in test scheme.             |
| 25-16 | Reserved        | 0     | Read returns 0. Writes have no effect.                                                                                                                                                               |
| 15-0  | RAM CHIP SELECT |       | RAM Chip Select. This field is used to store the RAM chip select value for the redundant address decode and compare logic. The stored value is passed as test stimulus for the built-in test scheme. |

### 6.7.10 TCRAM Module Parity Error Address Register (RAMPERRADDR)

The RAMPERRADDR register, shown in [Figure 6-12](#) and described in [Table 6-11](#), stores the address for which an address-parity error was detected.

**Figure 6-12. TCRAM Module Parity Error Address Register (RAMPERRADDR) [offset = 3Ch]**

|                              |    |                              |          |
|------------------------------|----|------------------------------|----------|

| R-0                          |    | R-U                          |          |
| 15                           | 3  | 2                            | 0        |
| ADDRESS PARITY ERROR ADDRESS |    |                              | Reserved |
| R-U                          |    |                              | R-0      |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 6-11. TCRAM Module Parity Error Address Register (RAMPERRADDR) Field Descriptions**

| Bit   | Field                        | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-23 | Reserved                     | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 22-3  | ADDRESS PARITY ERROR ADDRESS |       | Parity Error Address. This register stores the double-word boundary (bits 22-3) of the TCM access address for which there was an address parity error. This register must be read-cleared to enable further error address captures. Reading the register does not clear the register contents but enables the register to be updated with a new parity error address. This is a 64-bit-aligned address is stored as an offset from the base of the TCRAM or ECC memory. |
| 2-0   | Reserved                     | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## ***Programmable Built-In Self-Test (PBIST) Module***

This chapter describes the programmable built-in self-test (PBIST) controller module used for testing the on-chip memories on the Hercules microcontrollers.

| Topic                                               | Page |

## 7.1 Overview

The PBIST (Programmable Built-In Self-Test) controller architecture provides a run-time-programmable memory BIST engine for varying levels of coverage across many embedded memory instances.

### 7.1.1 Features of PBIST

- Information regarding on-chip memories, memory groupings, memory background patterns and test algorithms stored in dedicated on-chip PBIST ROM
- Host processor interface to configure and start BIST of memories
- Supports testing of PBIST ROM itself as well
- Supports testing of each memory at its maximum access speed in application
- Implements intelligent clock gating to conserve power

---

**NOTE:** Refer the device datasheet for the maximum PBIST ROM clock frequency supported.

---

### 7.1.2 PBIST vs. Application Software-Based Testing

The PBIST architecture consists of a small coprocessor with a dedicated instruction set targeted specifically toward testing memories. This coprocessor executes test routines stored in the PBIST ROM and runs them on multiple on-chip memory instances. The on-chip memory configuration information is also stored in the PBIST ROM. The testing is done in parallel for each of the CPU data RAMs, while it is done sequentially for the rest of the memories.

The PBIST Controller architecture offers significant advantages over tests running on the main Cortex-R4F processor (application software-based testing):

- Embedded CPUs have a long access path to memories outside the tightly-couple memory sub-system, while the PBIST controller has a dedicated path to the memories specifically for the self-test
- Embedded CPUs are designed for their targeted use and are often not easily programmed for memory test algorithms.
- The memory test algorithm code on embedded CPUs is typically significantly larger than that needed for PBIST.
- The embedded CPU is significantly larger than the PBIST controller.

### 7.1.3 PBIST Block Diagram

Figure 7-1 illustrates the basic PBIST blocks and its wrapper logic for the device.

**Figure 7-1. PBIST Block Diagram**

### 7.1.3.1 On-chip ROM

The on-chip ROM contains the information regarding the algorithms and memories to be tested.

### 7.1.3.2 Host Processor Interface to the PBIST Controller Registers

The Cortex-R4F CPU can select the algorithm and RAM groups for the memories' self-test from the on-chip ROM based on the application requirements. Once the self-test has executed, the CPU can query the PBIST controller registers to identify any memories that failed the self-test and to then take appropriate next steps as required by the application's author.

### 7.1.3.3 Memory Data Path

This is the read and write data path logic between different system and peripheral memories tightly coupled to the PBIST memory interface. The PBIST controller executes each selected algorithm on each valid memory group sequentially until all the algorithms are executed.

---

**NOTE:** Not all algorithms are designed to run on all RAM groups. If an algorithm is selected to run on an incompatible memory, this will result in a failure. Refer to [Table 2-5](#) and [Table 2-6](#) for RAM grouping and algorithm information.

---

## 7.2 RAM Grouping and Algorithm

[Table 2-5](#) gives the list of RAM groups and their types supported on the device. [Table 2-6](#) maps the different algorithms supported in application mode for the RAM groups with the background patterns used for the particular algorithm.

---

**NOTE:** March13 is the most recommended algorithm for the memory self-test.

---

## 7.3 PBIST Flow

Figure 7-2 illustrates the memory self-test flow.

**Figure 7-2. PBIST Memory Self-Test Flow Diagram**

### 7.3.1 PBIST Sequence

1. Configure the device clock sources and domains so that they are running at their target frequencies.
2. Program the HCLK to PBIST ROM clock ratio by configuring the ROM\_DIV field (bits 9:8) of the MSTGCR register of the system module. Check the device datasheet for the maximum supported PBIST ROM clock frequency.
3. Enable PBIST Controller by setting bit 1 of MSIENA register in system module.
4. Enable the PBIST self-test by writing a value of 0x0A to bits 3:0 of the MSTGCR in the system module.
5. Wait for N VBUS clock cycles based on the HCLK to PBIST ROM clock ratio:  
 N = 16 when HCLK:PBIST ROM clock is 1:1  
 N = 32 when HCLK:PBIST ROM clock is 1:2  
 N = 64 when HCLK:PBIST ROM clock is 1:4  
 N = 64 when HCLK:PBIST ROM clock is 1:8
6. Write 3h to PACT register to enable the PBIST internal clocks and ROM interface clock.
7. Program the ALGO register to decide which algorithm from the instruction ROM must be selected (the default value of ALGO register is all 1's, meaning all algorithms are selected). Similarly, program the RINFOL and RINFOU registers to indicate whether a particular RAM group in the instruction ROM would get executed or not.

---

**NOTE:** In case of RAM Override (Override Register (OVER) = 00), the user should make sure that only the algorithms that run on similar RAMs are selected. If a single port algorithm is selected in ROM Algorithm Mask Register (ALGO), the RAM Info Mask Lower Register (RINFOL) and RAM Info Mask Upper Register (RINFOU) must select only the single port RAM's. The same applies for two port RAM's. Check [Table 2-5](#) for information on the memory types.

---

8. Program OVER = 1h to run PBIST self-test without RAM override. Program OVER = 0 to run PBIST self-test with RAM Override.
9. Write a value of 3h to the ROM mask register should the microcode for the Algorithms as well as the RAM groups loaded from the on chip PBIST ROM.
10. Write DLR (Data Logger register) with 14h to configure the PBIST run in ROM mode and to enable the configuration access. This starts the memory self-tests.
11. Wait for the PBIST self-test done by polling MSTDONE bit of MSTCGSTAT register in System Module.
12. Once self-test is completed, check the Fail Status register FSRF0.  
 In case there is a failure (FSRF0 = 1h)
  - (a) Read RAMT register which indicates the RGS and RDS values of the failure RAM
  - (b) Read FSRC0 and FSRC1 registers which contains the failure count
  - (c) Read FSRA0 and FSRA1 registers which contains the address of first failure
  - (d) Read FSRDL0 and FSRDL1 registers which contains the failure data.
  - (e) Write a value of 2h to the STR register to resume the test.
 In case there is no failure (FSRF0 = 0) the memory self-test is completed.
  - (a) Disable the PBIST internal and ROM clocks by writing a 0 to the PACT register.
  - (b) Disable the PBIST self-test by writing a value of 5h to bits 3:0 of the MSTGCR in the system module
 Repeat steps 2 through 9 for subsequent runs with different RAM group and algorithm configurations.
13. After required Memory tests are completed, Resume or Start the Normal Application software.

---

**NOTE:** The contents of the selected memory before the test will be completely lost. User software must take care of data backup if required. Typically the PBIST tests are carried out at the beginning of Application software.

---

**NOTE:** Memory test fail information is reported in terms of RGS:RDS and not RAM GROUP. Check [Table 2-5](#) for information on the RGS:RDS information applicable to each memory being tested.

## 7.4 Memory Test Algorithms on the On-chip ROM

This section provides a brief description for some of the test algorithms used for memory self-test.

### 1. March13N:

- March13N is the baseline test algorithm for SRAM testing. It provides the highest overall coverage. The other algorithms provide additional coverage of otherwise missed boundary conditions of the SRAM operation.
- The concept behind the general march algorithm is to indicate:
  - The bit cell can be written and read as both a 1 and a 0.
  - The bits around the bit cell do not affect the bit cell.
- The basic operation of the march is to initialize the array to a know pattern, then march a different pattern through the memory.
- Type of faults detected by this algorithm:
  - Address decoder faults
  - Stuck-At faults
  - Coupled faults
  - State coupling faults
  - Parametric faults
  - Write recovery faults
  - Read/write logic faults

### 2. Map Column:

- The MAP COLUMN algorithm is used to identify bit line sensitivities in the memory array. The memory array is loaded with a row stripe pattern of all 1s in the first row followed by all 0s in the second row and repeated throughout the array. Then the values are read down each column on consecutive cycles. The pattern in memory is inverted and run the column reads again.
- This particular pattern is looking for the following SRAM failure mechanisms:
  - Leakage due to a low resist path in a bit
  - An Open in the bit cell
  - Leakage on a BIT or BITN line
  - Miss-balance in the sense amp
  - Leakage in the sense
  - High resist in the sense amp
  - Failure of the pre-charge circuits after read operations

### 3. Pre-Charge:

- The Pre-Charge algorithm exercises the pre-charge capability within the SRAM array. It is important to specifically target this issue as it is the only part of the analog portion of the SRAM that is frequency sensitive.
- Similar to the MAP COLUMN algorithm, this algorithm works its way down the columns of the SRAM. However, unlike the MAP COLUMN, this algorithm sandwiches a write between two reads to force the worst-case conditions for the pre-charge circuits in the array.
- This test will fail when an increase in system frequency nears the minimum access time of the array, at this boundary:
  - High voltage should operate better than low voltage.
  - Likewise, low temperature should operate better than high temperature.

**4. DOWN1a:**

- The Down1 pattern forces the switching of all data bits and most address bits on consecutive read cycles. This is primarily a read/write test of the CPU/memory subsystem.
- The aggressive writes target at-speed write failures.
- It also targets row/column decode in the memory array.
- Targets the sense amps and sense amp multiplexors.
- Memory array output buffers.
- This algorithm operates as follows:
  - Load 1st half of the memory under test with one pattern.
  - Load 2nd half of the memory under test with the bit-wise inverse of the pattern.
  - Alternate sequential reads sequences between one sequence starting at the beginning of the array and a second sequence starting at the end of the array.
  - Upon completion of the read back, invert the patterns in both halves of the array and repeat the above step.
  - Perform an aggressive write sequence by alternating writes between the bottom half of the memory upwards with a data pattern and the top half of the memory downwards with the inverse data pattern.
  - Invert the data pattern for the above two steps to perform another sequence of aggressive writes.

**5. DTXN2a:**

This algorithm is used to target the global column decode Logic.

## 7.5 PBIST Control Registers

PBIST controller uses configuration registers for programming the algorithm and its execution. All the configuration registers are memory mapped for access by the CPU through the Peripheral Bus interface. The base address for the control registers is FFFF E400h.

**NOTE:** There is no watchdog functionality implemented in the PBIST controller. If a bad code is executed, the PBIST will run forever. The PBIST controller does not guard against this situation.

Registers are accessible only when the clock to PBIST controller is active. The clock is activated by first writing 0x3 to PACT register.

**Table 7-1. PBIST Registers**

| Offset      | Acronym  | Register Description                                 | Section                        |

### 7.5.1 RAM Configuration Register (RAMT)

This register is divided into the following internal registers, none of which have a default value after reset. [Figure 7-3](#) and [Table 7-2](#) illustrate this register.

**Figure 7-3. RAM Configuration Register (RAMT) [offset = 0160h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 7-2. RAM Configuration Register (RAMT) Field Descriptions**

| Bit   | Field | Value | Description                                                                                            |
|-------|-------|-------|--------------------------------------------------------------------------------------------------------|
| 31-24 | RGS   |       | Ram Group Select. Refer <a href="#">Table 2-5</a> for information on the RGS value for each memory.    |
| 23-16 | RDS   |       | Return Data Select. Refer <a href="#">Table 2-5</a> for information on the RDS values for each memory. |
| 15-8  | DWR   |       | Data Width Register                                                                                    |
| 7-6   | SMS   |       | Sense Margin Select Register                                                                           |
| 5-2   | PLS   |       | Pipeline Latency Select                                                                                |
| 1-0   | RLS   |       | RAM Latency Select                                                                                     |

This register provides the information regarding the memory being currently tested. In case of a PBIST failure, the application can read this register to identify the RGS:RDS values for the memory that failed the self-test.

## 7.5.2 Datalogger Register (DLR)

This register puts the PBIST controller into the appropriate comparison modes for data logging. [Figure 7-4](#) and [Table 7-3](#) illustrate this register.

**Figure 7-4. Datalogger Register (DLR) [offset = 0164h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 7-3. Datalogger Register (DLR) Field Descriptions**

| Bit    | Field    | Value | Description                                                                                                                   |
|--------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------|
| 31 - 5 | Reserved | 0     | Reads return 0. Do not change these bits from their default value.                                                            |
| 4      | DLR4     |       | Config access: setting this bit allows the host processor to configure the PBIST controller registers                         |
| 3      | Reserved | 1     | Do not change this bit from its default value of 1.                                                                           |
| 2      | DLR2     |       | ROM-based testing: setting this bit enables the PBIST controller to execute test algorithms that are stored in the PBIST ROM. |
| 1 - 0  | Reserved | 00    | Do not change these bits from their default value of 00.                                                                      |

- DLR2: ROM-based testing mode**

Writing a 1 to this register starts the ROM-based testing. This register is used to initiate ROM-based testing from Config and ATE interfaces. Also, since a 1 in this bit position means the instruction ROM is used for memory testing, all the intermediate interrupts and PBIST done signal after each memory test are masked until all the selected algorithms in the ROM are executed for all RAM groups. However, a failure would stop the test and report the status immediately.

- DLR4: Config access mode**

This mode, when set, indicates the CPU is being used to access PBIST.

### 7.5.3 PBIST Activate/ROM Clock Enable Register (PACT)

This is the first register that needs to be programmed to activate the PBIST controller. Bit [0] is used for static clock gating, and unless a '1' is written to this bit, all the internal PBIST clocks are shut off. Bit [1] is for turning on the clock going to the instruction ROM. [Figure 7-5](#) and [Table 7-4](#) illustrate this register.

**Figure 7-5. PBIST Activate/ROM Clock Enable Register (PACT) [offset = 0180h]**

|     |          |  |  |  |  |  |  |  |  |  |  |       |   |       |   |    |
|-----|----------|--|--|--|--|--|--|--|--|--|--|-------|---|-------|---|----|
| 31  | Reserved |  |  |  |  |  |  |  |  |  |  |       |   |       |   | 16 |
| R-0 |          |  |  |  |  |  |  |  |  |  |  |       |   |       |   |    |
| 15  | Reserved |  |  |  |  |  |  |  |  |  |  |       | 2 | 1     | 0 |    |
| R-0 |          |  |  |  |  |  |  |  |  |  |  | PACT1 |   | PACT0 |   |    |
| R-0 |          |  |  |  |  |  |  |  |  |  |  | R/W-0 |   | R/W-0 |   |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 7-4. PBIST Activate/ROM Clock Enable Register (PACT) Field Descriptions**

| Bit  | Field    | Value | Description                                                |
|------|----------|-------|------------------------------------------------------------|
| 31-2 | Reserved | 0     | Read returns 0. Writes have no effect.                     |
| 1    | PACT1    | 0     | PBIST Activate<br>Clock to on chip ROM is disabled         |
|      |          | 1     | Normal PBIST operation for ROM based testing               |
| 0    | PACT0    | 0     | ROM Clock Enable Register<br>Disable internal PBIST clocks |
|      |          | 1     | Enable internal PBIST clocks                               |

- **PACT0**

This bit must be set to turn on internal PBIST clocks. Setting this bit asserts an internal signal that is used as the clock gate enable. As long as this bit is 0, any access to PBIST will not go through, and PBIST will remain in an almost zero-power mode.

- **PACT1**

Setting this bit turns on the clock going to the instruction ROM.

**NOTE:** This register must be programmed to 3h during application self-test.

### 7.5.4 PBIST ID Register

Functionality of this register is described in [Figure 7-6](#) and [Table 7-5](#).

**Figure 7-6. PBIST ID Register [offset = 184h]**

|          |  |  |  |  |  |  |  |          |   |  |  |  |  |  |  |    |   |
|----------|--|--|--|--|--|--|--|----------|---|--|--|--|--|--|--|----|---|
| 31       |  |  |  |  |  |  |  |          |   |  |  |  |  |  |  | 16 |   |
| Reserved |  |  |  |  |  |  |  |          |   |  |  |  |  |  |  |    |   |
| R-0      |  |  |  |  |  |  |  |          |   |  |  |  |  |  |  |    |   |
| 15       |  |  |  |  |  |  |  | 8        | 7 |  |  |  |  |  |  |    | 0 |
| Reserved |  |  |  |  |  |  |  | PBIST ID |   |  |  |  |  |  |  |    |   |
| R-0      |  |  |  |  |  |  |  | R/W-0    |   |  |  |  |  |  |  |    |   |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 7-5. PBIST ID Register Field Descriptions**

| Bit  | Field    | Value | Description                                                                                        |
|------|----------|-------|----------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reads return 0. Writes have no effect.                                                             |
| 7-0  | PBIST ID |       | This is a unique ID assigned to each PBIST controller in a device with multiple PBIST controllers. |

### 7.5.5 Override Register (OVER)

Functionality of the register is described in [Figure 7-7](#) and [Table 7-6](#).

**Figure 7-7. Override Register (OVER) [offset = 0188h]**

|          |  |  |  |  |  |  |  |  |  |  |           |   |       |       |   |    |
|----------|--|--|--|--|--|--|--|--|--|--|-----------|---|-------|-------|---|----|
| 31       |  |  |  |  |  |  |  |  |  |  |           |   |       |       |   | 16 |
| Reserved |  |  |  |  |  |  |  |  |  |  |           |   |       |       |   |    |
| R-0      |  |  |  |  |  |  |  |  |  |  |           |   |       |       |   |    |
| 15       |  |  |  |  |  |  |  |  |  |  |           | 3 | 2     | 1     | 0 |    |

| R-0      |  |  |  |  |  |  |  |  |  |  | R-0       |   | R-0   | R/W-1 |   |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 7-6. Override Register (OVER) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                              |
|------|----------|-------|--------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                   |
| 2    | Reserved | 0     | Reserved. This bit must not be changed from its default value of 0.                                                      |
| 1    | Reserved | 0     | Reserved. This bit must not be changed from its default value of 0.                                                      |
| 0    | OVER0    | 0     | RINFO Override Bit<br>The RAM info registers RINFOL and RINFOU are used to select the memories for test                  |
|      |          | 1     | The memory information available from ROM will override the RAM selection from the RAM info registers RINFOL and RINFOU. |

- OVER0**

While doing ROM-based testing, each algorithm downloaded from the ROM has a memory mask associated with it that defines the applicable memory groups the algorithm will be run on. By default, this bit is set to 1, which means the memory mask that is downloaded from the ROM will overwrite the RAM info registers. The override bit can be reset by writing a 0 to it. In this case, the application can select the RAM groups to be tested by configuring the RAM info registers.

**NOTE:** When this override bit = 0, each algorithm selected in ALGO register will run on each RAM selected in RINFOL and RINFOU register. It must be ensured that:

1. Only the same type of memories (single port or two port) are selected, and
2. Only memories that are valid for all algorithms enabled via the ALGO register are selected.

If the above two requirements are not met, the memory self-test will fail.

### 7.5.6 Fail Status Fail Register (FSRF0)

This register indicates if a Port0 failure occurred during a memory self-test. Bit 0 gets set whenever a failure occurs. Functionality of the register is described in [Figure 7-8](#) and [Table 7-7](#).

**Figure 7-8. Fail Status Fail Register 0 (FSRF0) [offset = 0190h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 7-7. Fail Status Fail Register 0 (FSRF0) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                             |
|------|----------|-------|---------------------------------------------------------------------------------------------------------|
| 31-1 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                  |
| 0    | FSRF0    | 0     | Fail Status 0. This bit would be cleared by reset of the module using MSTGCR register in system module. |
|      |          | 0     | No Failure Occurred                                                                                     |
|      |          | 1     | Indicates a failure on Port 0                                                                           |

### 7.5.7 Fail Status Count Registers (FSRC0 and FSRC1)

These registers keep count of the number of failures observed during the memory self-test. The PBIST controller stops executing the memory self-test whenever a failure occurs in any memory instance for any of the test algorithms. The value in FSRC0 / FSRC1 gets incremented by one whenever a failure occurs and gets decremented by one when the failure is processed. FSRC0 is for Port 0 and FSRC1 is for Port 1. [Figure 7-9](#) and [Table 7-8](#) illustrate the FSRC0 register, while [Figure 7-10](#) and [Table 7-9](#) illustrate the FSRC1 register.

**Figure 7-9. Fail Status Count 0 Register (FSRC0) [offset = 0198h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 7-8. Fail Status Count 0 Register (FSRC0) Field Descriptions**

| Bit  | Field    | Value | Description                                                      |
|------|----------|-------|------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reads return 0. Writes have no effect.                           |
| 7-0  | FSRC0    |       | Fail Status Count 0. Indicates the number of failures on port 0. |

**Figure 7-10. Fail Status Count Register 1 (FSRC1) [offset = 019Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 7-9. Fail Status Count Register 1 (FSRC1) Field Descriptions**

| Bit  | Field    | Value | Description                                                      |
|------|----------|-------|------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reads return 0. Writes have no effect.                           |
| 7-0  | FSRC1    |       | Fail Status Count 1. Indicates the number of failures on port 1. |

### 7.5.8 Fail Status Address Registers (FSRA0 and FSRA1)

These registers capture the memory address of the first failure on port 0 and port 1 respectively. [Figure 7-11](#) and [Table 7-10](#) illustrate the FSRA0 register, while [Figure 7-12](#) and [Table 7-11](#) illustrate the FSRA1 register.

**Figure 7-11. Fail Status Address 0 Register (FSRA0) [offset = 01A0h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 7-10. Fail Status Address 0 Register (FSRA0) Field Descriptions**

| Bit   | Field    | Value | Description                                                       |
|-------|----------|-------|-------------------------------------------------------------------|
| 31-16 | Reserved | 0     | Read returns 0. Writes have no effect.                            |
| 15-0  | FSRA0    |       | Fail Status Address 0. Contains the address of the first failure. |

**Figure 7-12. Fail Status Address 1 Register (FSRA1) [offset = 01A4h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 7-11. Fail Status Address 1 Register (FSRA1) Field Descriptions**

| Bit   | Field    | Value | Description                                                       |
|-------|----------|-------|-------------------------------------------------------------------|
| 31-16 | Reserved | 0     | Read returns 0. Writes have no effect.                            |
| 15-0  | FSRA1    |       | Fail Status Address 1. Contains the address of the first failure. |

### 7.5.9 Fail Status Data Registers (FSRDL0 and FSRDL1)

These registers are used to capture the failure data in case of a memory self-test failure. FSRDL0 corresponds to Port 0, while FSRDL1 corresponds to Port 1. [Figure 7-13](#) and [Table 7-12](#) illustrate the FSRDL0 register, while [Figure 7-14](#) and [Table 7-13](#) illustrate the FSRDL1 register.

**Figure 7-13. Fail Status Data Register 0 (FSRDL0) [offset = 01A8h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 7-12. Fail Status Data Register 0 (FSRDL0) Field Descriptions**

| Bit  | Field  | Value | Description            |
|------|--------|-------|------------------------|
| 31-0 | FSRDL0 |       | Failure data on port 0 |

**Figure 7-14. Fail Status Data Register 1 (FSRDL1) [offset = 01B0h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 7-13. Fail Status Data Register 1 (FSRDL1) Field Descriptions**

| Bit  | Field  | Value | Description            |
|------|--------|-------|------------------------|
| 31-0 | FSRDL1 |       | Failure data on port 1 |

### 7.5.10 ROM Mask Register (ROM)

This two-bit register sets appropriate ROM access modes for the PBIST controller. The default value is 11b. This register is illustrated in [Figure 7-15](#). It can be programmed according to [Table 7-14](#).

**Figure 7-15. ROM Mask Register (ROM) [offset = 01C0h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 7-14. ROM Mask Register (ROM) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                            |
|------|----------|-------|--------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                 |
| 1-0  | ROM      | 0     | No information is used from ROM                                                                        |
|      |          | 1h    | Only RAM Group information from ROM                                                                    |
|      |          | 2h    | Only Algorithm information from ROM                                                                    |
|      |          | 3h    | Both Algorithm and RAM information from ROM. This option should be selected for application self-test. |

### 7.5.11 ROM Algorithm Mask Register (ALGO)

This register is used to indicate the algorithm(s) to be used for the memory self-test routine. Each bit corresponds to a specific algorithm. For example, bit 0 controls whether algorithm 1 is enabled or not. [Figure 7-16](#) and [Table 7-15](#) illustrate this register.

**Figure 7-16. ROM Algorithm Mask Register (ALGO) [offset = 01C4h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 7-15. Algorithm Mask Register (ALGO) Field Descriptions**

| Bit  | Field | Value | Description                         |
|------|-------|-------|-------------------------------------|
| 31   |       | 0     | Algorithm 32 is not selected        |
|      |       | 1     | Selects algorithm 32 for PBIST run  |
| 30   |       | 0     | Algorithm 31 is not selected        |
|      |       | 1     | Selects algorithm 31 for PBIST run  |
| ...  |       |       |                                     |
| 0    |       | 0     | Algorithm 1 is not selected         |
|      |       | 1     | Selects algorithm 1 for PBIST run   |
| 31-0 |       | 0     | None of the algorithms are selected |

**NOTE:** Please refer to [Table 2-6](#) for available algorithms and the memories on which each algorithm can be run.

### 7.5.12 RAM Info Mask Lower Register (RINFOL)

This register is to select RAM groups to run the algorithms selected in the ALGO register. For an algorithm to be executed on a particular RAM group, the corresponding bit in this register must be set to '1'. The default value of this register is all '1's, which means all the RAM Groups are selected. [Figure 7-17](#) and [Table 7-16](#) illustrate this register.

The information from this register is used only when bit 0 in OVER register is not set.

**Figure 7-17. RAM Info Mask Lower Register (RINFOL) [offset = 01C8h]**

| 31-0 |       | 0     | None of the RAM Groups 1 to 32 are selected |

**NOTE:** Please refer to [Table 2-5](#) for RAM info groups.

### 7.5.13 RAM Info Mask Upper Register (RINFOU)

This register is to select RAM groups to run the algorithms selected in the ALGO register. For an algorithm to be executed on a particular RAM group, the corresponding bit in this register should be set to '1'. The default value of this register is all '1's, which means all the RAM Info Groups would be selected. [Figure 7-18](#) and [Table 7-17](#) illustrate this register.

**Figure 7-18. RAM Info Mask Upper Register (RINFOU) [offset = 01CCh]**

| Bit  | Field | Value | Description                              |
|------|-------|-------|------------------------------------------|
| 31   |       | 0     | RAM Group 64 is not selected             |
|      |       | 1     | Selects group 64 for PBIST run           |
| 30   |       | 0     | RAM Group 63 is not selected             |
|      |       | 1     | Selects RAM group 63 for PBIST run       |
| 0    |       | 0     | RAM Group 33 is not selected             |
|      |       | 1     | Selects RAM Group 33 for PBIST run       |
| 31-0 |       | 0     | None of RAM Groups 33 to 64 are selected |

## 7.6 PBIST Configuration Example

The following examples assume that the PLL is locked and selected as clock source with HCLK = 160 MHz and VCLK = 80 MHz.

### 7.6.1 Example 1 : Configuration of PBIST Controller to Run Self-Test on RAM Group 3

This example explains the configurations for running March13, Down1A and Map Column algorithms on RAM Group 3 (see device datasheet for RAM Group information).

1. Program the HCLK to PBIST ROM clock ratio to 1:2 in System Module.  
MSTGCR[9:8] = 1
2. Enable PBIST Controller in System Module.  
MSIENA[31:0] = 0x00000001
3. Enable the PBIST self-test in System Module.  
MSTGCR[3:0] = 0xA
4. Wait for at least 32 VCLK cycles in a software loop.
5. Enable the Pbist internal clocks and ROM interface clock.  
PACT = 0x3
6. Disable RAM Override. This will make the PBIST controller use the information provided by the application in the RINFOx and ALGO registers for the memory self-test.  
OVER = 0x0;
7. Select the Algorithm (refer [Table 2-6](#)).  
ALGO = 0x00000054 (Algo 3 = March13N, Algo 5 = down1A\_red, Algo 7 = Map column for two-port RAM Group 3)
8. Program the RAM group Info to select RAM Group 3 (refer [Table 2-5](#)).  
RINFOL = 0x00000004 (select RAM Group 3)  
RINFOU = 0x00000000 (since this device supports only 28 RAM Groups)
9. Select both Algorithm and RAM information from on chip PBIST ROM.  
ROM = 0x3
10. Configure PBIST to run in ROM Mode and start PBIST run.  
DLR = 0x14
11. Wait for PBIST test to complete by polling MSTDONE bit in System Module.  
while (MSTDONE !=1);
12. Once self-test is completed, check the Fail Status register FSRF0.
  - (a) In case there is a failure (FSRF0 = 0x01):
    - (i) Read RAMT register which indicates the RGS and RDS values of the failure RAM.
    - (ii) Read FSRC0 and FSRC1 registers which contains the failure count.
    - (iii) Read FSRA0 and FSRA1 registers which contains the address of first failure.
    - (iv) Read FSRDL0 and FSRDL1 registers which contains the failure data.
    - (v) Resume the Test if required using Program Control register (offset = 0x16C) STR = 2.
  - (b) In case there is no failure (FSRF0 = 0x00), the memory self-test is completed:
    - (i) Disable the PBIST internal and ROM clocks.  
PACT = 0
    - (ii) Disable the PBIST self-test.  
MSTGCR[3:0] = 0x5

### 7.6.2 Example 2 : Configuration of PBIST Controller to Run Self-Test on ALL RAM Groups

This example explains the configurations for running March13, Down1A and Mapcolumn algorithms on all RAM groups defined in the PBIST ROM.

1. Program the HCLK to PBIST ROM clock ratio to 1:2 in System Module.  
MSTGCR[9:8] = 1
2. Enable PBIST Controller in System Module.  
MSIENA[31:0] = 0x00000001
3. Enable the PBIST self-test in System Module.  
MSTGCR[3:0] = 0xA
4. Wait for at least 32 VCLK cycles in a software loop.
5. Enable the Pbist internal clocks and ROM interface clock.  
PACT = 0x3
6. Enable RAM Override.  
OVER = 0x1;
7. Select the Algorithms to be run (refer [Table 2-6](#)).  
ALGO = 0x000000FC (select March13N, Down1A and Map Column algorithms for single-port and two-port RAMs)
8. Select both Algorithm and RAM information from on chip PBIST ROM.  
ROM = 0x3
9. Configure PBIST to run in ROM Mode and kickoff PBIST test.  
DLR = 0x14
10. Wait for PBIST test to complete by polling MSTDONE bit in System Module.  
while (MSTDONE !=1);
11. Once self-test is completed, check the Fail Status register FSRF0:
  - (a) In case there is a failure (FSRF0 = 0x01):
    - (i) Read RAMT register which indicates the RGS and RDS values of the failure RAM.
    - (ii) Read FSRC0 and FSRC1 registers which contains the failure count.
    - (iii) Read FSRA0 and FSRA1 registers which contains the address of first failure.
    - (iv) Read FSRDL0 and FSRDL1 registers which contains the failure data.
    - (v) Resume the Test if required using Program Control register (offset = 0x16C) STR = 2.
  - (b) In case there is no failure (FSRF0 = 0x00), the memory self-test is completed:
    - (i) Disable the PBIST internal and ROM clocks.  
PACT = 0
    - (ii) Disable the PBIST self-test.  
MSTGCR[3:0] = 0x5

## ***CPU Self-Test Controller (STC) Module***

---

---

This chapter describes the basics and configuration of the CPU self-test controller present in the device.

| <b>Topic</b>                                    | <b>Page</b> |

| <b>8.4 STC Control Registers .....</b>          | <b>362</b>  |
| <b>8.5 STC Configuration Example .....</b>      | <b>370</b>  |

## 8.1 General Description

The CPU self-test controller (STC) is used to test the ARM-CPU core using the Deterministic Logic Built-in Self-Test (LBIST) Controller as the test engine. To achieve better coverage for the self-test of complex cores like Cortex-R4, on-chip logic BIST is the preferred solution.

### 8.1.1 CPU Self-Test Controller Features

The CPU self-test controller has the following features:

- Capable of running the complete test as well as running a few intervals at a time
  - Ability to continue from the last executed interval (test set) as well as the ability to restart from the beginning (first test set)
  - Total of 24 intervals supported in this device
- Complete isolation of the self-tested CPU core from the rest of the system during the self-test run
  - The self-tested CPU core master bus transaction signals are configured to be in idle mode during the self-test run
  - Any master access to the CPU core under self-test (example: DMA access to CPU TCM) will be held until the completion of the self-test
- Ability to capture the failure interval number
- Timeout counter for the CPU self-test run as a fail-safe feature
- Able to read the MISR data (shifted from LBIST controller) of the last executed interval of the self-test run for debugging purposes
- STCCLK determines the self-test execution speed, STC clock divider (STCCLKDIV) register in the system module is used to divide HCLK (system clock) to generate STCCLK

### 8.1.2 STC Block Diagram

STC module provides an interface to the LBIST controller implemented on the core.

The CPU STC is composed of following blocks of logic:

- ROM Interface
- FSM and Sequence Control
- Register Block
- Peripheral Bus Interface (VBUSP Interface)
- STC Bypass/ATE Interface

#### 8.1.2.1 ROM Interface

This block handles the ROM address and control signal generation to read the self-test microcode from the ROM. The test microcode and golden signature value for each interval are stored in ROM.

##### 8.1.2.1.1 FSM and Sequence Control

This block generates the signals and data to the LBIST controller based on the seed, test\_type and scan chain depth.

##### 8.1.2.1.2 Clock Control

The CLOCK CNTRL sub-block handles the internal clock selection and clock generation for the ROM and LBIST controller.

#### 8.1.2.2 Register Block

This block handles the control of the self-test controller. This block contains various configuration and status registers which provide the result of a self-test run. These registers are memory mapped and accessible through the Peripheral Bus (VBUSP) Interface. This block controls the reseeding (reloading the existing seed of the PRPG) in the LBIST controller.

### 8.1.2.3 STC Bypass / ATE Interface

This is a production test interface. Only for TI internal use.

### 8.1.2.4 Peripheral Bus (VBUSP) Interface

STC control registers are accessed through Peripheral Bus (VBUSP) Interface. During application programming, configuration registers are programmed through the Peripheral Bus Interface to enable and run the self-test controller.

**Figure 8-1. STC Block Diagram**

## 8.2 Application Self-Test Flow

This section describes the STC module configuration and the application self-test flow that the user should follow for successful execution.

The following two configurations must be part of the STC initialization code:

- STC clock rate configuration, STC clock divider (STCCLKDIV) register in system module is used to divide HCLK(system clock) to generate STCCLK
- Clear SYSESR register before triggering an STC test

### 8.2.1 STC Module Configuration

- Configure the test interval count using STCGCR0[31:16] register. A maximum of 24 intervals are supported in the device. The user can run 24 intervals together or in slices. If the tests are run in slices, the user software can specify to the self-test controller whether to continue the run from the next interval onwards or to restart from interval 0 using bit STCGCR0[0]. This bit gets reset after the completion of the self-test run.
- Configure self-test run timeout counter preload register STCTPR. This register contains the total number of VBUS clock cycles it will take before a self-test timeout error (TO\_ERR) will be triggered after the initiation of the self-test run.
- Enable CPU self-test by writing the enable key to STCGCR1 register.

### 8.2.2 Context Saving

STC generates a CPU reset after completion of the test regardless of pass or fail. The user can run the STC test during startup or can divide STC into 24 or fewer intervals and run them during normal operation.

If STC is ran only on startup, the user software need not save the CPU contents since the reset caused will go through all startup configurations. User should check the STCGSTAT register for the self-test status before going to the application software.

If STC is divided into intervals and ran, user software must save the CPU contents and reload them after the CPU reset caused by the completion of the STC test interval. The check for STC status should bypass STC run if the reset is caused by an STC run to prevent a cyclic reset, i.e., if reset is caused by STC the second time through, then it should not be ran again. The user should also check the STCGSTAT register for the self-test status before restoring the application software.

Following are some of the registers that are required to be backed up before and restored after self-test:

1. CPU core registers (all modes R0-R15, PC, CPSR)
2. CP15 System Control Coprocessor registers - MPU control and configuration registers, Auxiliary Control Register used to Enable ECC, Fault Status Register etc.
3. CP13 Coprocessor Registers - FPU configuration registers, General Purpose Registers
4. Hardware Break Point and watch point registers like BVR, BSR, WVR, WSR etc.

For more information on the CPU reset, please refer to the *Cortex-R4 Technical Reference Manual version r1p3*.

---

**NOTE:** Check all reset source flags in the SYSESR register after a CPU BIST execution. If a flag in addition to CPU reset is set, clear the CPU reset flag and service the other reset sources accordingly.

---

### 8.2.3 Entering CPU Idle Mode

After enabling the STC test by writing the STC enable key, the test is triggered only after the CPU is taken to idle mode by executing the CPU Idle Instruction **asm(" WFI")**.

### 8.2.4 Self-Test Completion and Error Generation

At the end of each interval, the 128 bit MISR value (reflected in registers CPUx\_CURMISR[3:0]) from the DBIST controller is shifted into the STC. This is compared with the golden MISR value stored in the ROM.

At the end of a CPU self-test, the STC controller updates the status flags in the Global Status Register (STCGSTAT) and resets the CPU. In case of a MISR mismatch or a test timeout, an error is generated through the ESM module. TEST\_ERR signal is asserted when an MISR miscompare occurs during the self-test. A TO\_ERR is asserted when a timeout occurs during the self-test, meaning the test could not complete within the time specified in the timeout counter preload register STCTPR. However, at the device level, these two errors are combined and mapped to a single ESM channel. To identify which error occurred, user software must check the global status register (STCGSTAT) and fail status register STCFSTAT in the ESM interrupt service routine.

Figure 8-2 illustrates the application self-test test flow chart, drawn based on the assumption that the device has gone through startup, necessary clocks initialized and SYSESR register bits cleared.

**Figure 8-2. Application Self-Test Flow Chart**

### 8.3 STC Test Coverage and Duration

The test coverage and number of test execution cycles (STCCLK) for each test interval when the device is running at HCLK = 180 MHz, VCLK = 90 MHz, and STCCLK = 90 MHz are shown in [Table 8-1](#).

**Table 8-1. STC Test Coverage and Duration**

| Intervals | Test Coverage | Test Cycle | Test Time (us) |
|-----------|---------------|------------|----------------|
| 0         | 0             | 0          | 0              |
| 1         | 62.13         | 1365       | 15.17          |
| 2         | 70.09         | 2730       | 30.33          |
| 3         | 74.49         | 4095       | 45.50          |

## 8.4 STC Control Registers

STC control registers are accessed through Peripheral Bus (VBUSP) interface. Read and write access in 8,16 and 32 bit are supported. The base address for the control registers is FFFF E600h.

**NOTE:** In suspend mode, all registers can be written irrespective of user or privilege mode.

**Table 8-3. STC Control Registers**

| Offset | Acronym       | Register Description                           | Section                       |

**Table 8-4. STC Global Control Register 0 (STCGCR0) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                           |
|-------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | INTCOUNT |       | Number of intervals of self-test run<br>This register specifies the number of intervals to run for the self-test run. This corresponds to the number of intervals to be ran from the value reflected in the current interval counter. |
| 15-1  | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                |
| 0     | RS_CNT   |       | Restart or Continue<br>This bit specifies whether to continue the run from next interval onwards or to restart from interval 0. This bit gets reset after the completion of a self-test run.                                          |
|       |          | 0     | Continue STC run from the previous interval.                                                                                                                                                                                          |
|       |          | 1     | Restart STC run from interval 0.                                                                                                                                                                                                      |

**NOTE:** On a powerup reset or system reset this register gets reset to its default values.

### 8.4.2 STC Global Control Register 1 (STCGCR1)

This register is described in [Figure 8-4](#) and [Table 8-5](#).

**Figure 8-4. STC Global Control Register 1 (STCGCR1) [offset = 04h]**

|     |          |  |  |  |  |  |  |  |         |   |   |  |    |
|-----|----------|--|--|--|--|--|--|--|---------|---|---|--|----|
| 31  | Reserved |  |  |  |  |  |  |  |         |   |   |  | 16 |
| R-0 |          |  |  |  |  |  |  |  |         |   |   |  |    |
| 15  | Reserved |  |  |  |  |  |  |  | 4       | 3 | 0 |  |    |
| R-0 |          |  |  |  |  |  |  |  | STC_ENA |   |   |  |    |
| R-0 |          |  |  |  |  |  |  |  | R/WP-5h |   |   |  |    |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after nPORST (power on reset) or System reset

**Table 8-5. STC Global Control Register 1 (STCGCR1) Field Descriptions**

| Bit  | Field    | Value      | Description                            |
|------|----------|------------|----------------------------------------|
| 31-4 | Reserved | 0          | Read returns 0. Writes have no effect. |
| 3-0  | STC_ENA  |            | Self-test run enable key               |
|      |          | Ah         | Self-test run enabled.                 |
|      |          | All Others | Self-test run disabled.                |

**NOTE:** On a powerup reset or system reset this register resets to its default values. Also this register automatically resets to its default values at the completion of a self-test run.

### 8.4.3 Self-Test Run Timeout Counter Preload Register (STCTPR)

This register is described in [Figure 8-5](#) and [Table 8-6](#).

**Figure 8-5. Self-Test Run Timeout Counter Preload Register (STCTPR) [offset = 08h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after nPORST (power on reset) or System reset

**Table 8-6. Self-Test Run Timeout Counter Preload Register (STCTPR)**

| Bit  | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------|-------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | RTOD  |       | <p>Self-test timeout count preload</p> <p>This register contains the total number of VBUS clock cycles it will take before an self-test timeout error (TO_ERR) will be triggered after the initiation of the self-test run. This is a fail safe feature to prevent the device from hanging up due to a run away test during the self-test.</p> <p>The preload count value gets loaded into the self-test time out down counter whenever a self-test run is initiated (STC_KEY is enabled) and gets disabled on completion of a self-test run.</p> |

**NOTE:** This register gets reset to its default value with Power on or system reset assertion.

### 8.4.4 STC Current ROM Address Register (STC\_CADDR)

This register is described in [Figure 8-6](#) and [Table 8-7](#).

**Figure 8-6. STC Current ROM Address Register (STC\_CADDR) [offset = 0Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after nPORST (power on reset) or System reset

**Table 8-7. STC Current ROM Address Register (STC\_CADDR) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                                                   |
|------|-------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ADDR  |       | <p>Current ROM Address</p> <p>This register reflects the current ROM address (for micro code load) which is the current value of the STC program counter.</p> |

**NOTE:** When the global configuration register restart bit STCGCR0[0] is set to a 1 on the start of a self-test run, on a powerup reset or system reset this register resets to all zeroes.

### 8.4.5 STC Current Interval Count Register (STCCICR)

This register is described in [Figure 8-7](#) and [Table 8-8](#).

**Figure 8-7. STC Current Interval Count Register (STCCICR) [offset = 10h]**

|    |          |    |
|----|----------|----|
| 31 | Reserved | 16 |
|    | R-0      |    |
| 15 | N        | 0  |
|    | R-0      |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 8-8. STC Current Interval Count Register (STCCICR) Field Descriptions**

| Bit   | Field    | Value | Description                                                          |
|-------|----------|-------|----------------------------------------------------------------------|
| 31-16 | Reserved | 0     | Read returns 0. Writes have no effect.                               |
| 15-0  | N        |       | Interval Number<br>This specifies the last executed interval number. |

**NOTE:** When the global configuration register restart bit STCGCR[0] is set to a 1 or on a powerup reset the current interval counter resets to the default value.

### 8.4.6 Self-Test Global Status Register (STCGSTAT)

This register is described in [Figure 8-8](#) and [Table 8-9](#).

**Figure 8-8. Self-Test Global Status Register (STCGSTAT) [offset = 14h]**

|          |  |   |           |           |
|----------|--|---|-----------|-----------|
| 31       |  |   |           | 8         |
| Reserved |  |   |           |           |
| R-0      |  |   |           |           |
|          |  | 2 | 1         | 0         |
| Reserved |  |   | TEST_FAIL | TEST_DONE |
| R-0      |  |   | R/WP-0    | R/WP-0    |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

**Table 8-9. Self-Test Global Status Register (STCGSTAT) Field Descriptions**

| Bit  | Field     | Value | Description                                                                                                                                                                                                                                                                                                                                                      |
|------|-----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved  | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                           |
| 1    | TEST_FAIL | 0     | Test Fail<br>Self-test run has not failed.                                                                                                                                                                                                                                                                                                                       |
|      |           | 1     | Self-test run has failed.                                                                                                                                                                                                                                                                                                                                        |
| 0    | TEST_DONE | 0     | Test Done<br>Not completed.                                                                                                                                                                                                                                                                                                                                      |
|      |           | 1     | Self-test run completed.<br>The test done flag is set to a 1 for any of the following conditions:<br>1. When the STC run is complete without any failure<br>2. When a failure occurs on a STC run<br>3. When a timeout failure occurs<br>Reset is generated to the CPU on which the STC run is being performed when TEST_DONE goes high (the test is completed). |

**NOTE:** The above 2 status bits can be cleared to their default values a disabled state to an enabled state. Additionally when the STC\_ENA Key is written from a disabled state to enabled state the 2 status flags get cleared to their default values. This register gets reset to its default value with power on reset assertion.

### 8.4.7 Self-Test Fail Status Register (STCFSTAT)

This register is described in [Figure 8-9](#) and [Table 8-10](#).

**Figure 8-9. Self-Test Fail Status Register (STCFSTAT) [offset = 18h]**

|          |  |  |        |           |           |
|----------|--|--|--------|-----------|-----------|
| 31       |  |  |        | 8         |           |
| Reserved |  |  |        |           |           |
| R-0      |  |  |        |           |           |
| 3        |  |  | 2      | 1         | 0         |
| Reserved |  |  | TO_ERR | CPU2_FAIL | CPU1_FAIL |
| R-0      |  |  | R/WP-0 | R/WP-0    | R/WP-0    |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after nPORST (power on reset) or System reset

**Table 8-10. Self-Test Fail Status Register (STCFSTAT) Field Descriptions**

| Bit  | Field     | Value | Description                                         |
|------|-----------|-------|-----------------------------------------------------|
| 31-3 | Reserved  | 0     | Read returns 0. Writes have no effect.              |
| 2    | TO_ERR    | 0     | No time out error occurred.                         |
|      |           | 1     | Self-test run failed due to a timeout error.        |
| 1    | CPU2_FAIL | 0     | CPU2 failure info<br>No MISR mismatch for CPU2.     |
|      |           | 1     | Self-test run failed due to MISR mismatch for CPU2. |
| 0    | CPU1_FAIL | 0     | CPU1 failure info<br>No MISR mismatch for CPU1.     |
|      |           | 1     | Self-test run failed due to MISR mismatch for CPU1. |

**NOTE:** The above 3 status bits can be cleared to their default values on a write of 1. Additionally when the STC\_ENA Key in STCGCR1 is written from a disabled state to an enabled state, the 3 status bits get cleared to their default values. This register gets reset to its default value with power on reset assertion.

### 8.4.8 CPU1 Current MISR Register (CPU1\_CURMISR[3:0])

This register is described in [Figure 8-10](#) through [Figure 8-13](#) and [Table 8-11](#).

**Figure 8-10. CPU1 Current MISR Register (CPU1\_CURMISR3) [offset = 1Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**NOTE:** This register gets reset to its default value with power on or system reset assertion.

#### 8.4.10 STCSCSCR (Signature Compare Self-Check Register)

This register is described in [Figure 8-18](#). This register is used to enable the selfcheck feature of the CPU Self-Test Controller's (STC) signature compare logic. Selfcheck can only be done for the STC interval-0 which can be achieved by setting STGCR0[0] to '0' ( restart) and STC run is expected to fail for signature mismatch. To proceed with regular CPU selftest STCSCSCR should be programmed to disable the selfcheck feature and STGCR0[0] to '0'. This register gets reset to its default value with any system reset assertion.

## 8.5 STC Configuration Example

The following examples assume that the PLL is locked and selected as the system clock source with HCLK = 180 MHz and VCLK = 90 MHz.

### 8.5.1 Example 1: Self-Test Run for 24 Interval

This example explains the configurations for running STC Test for maximum Test Intervals 24.

1. Maximum STC clock rate support at 180 MHz HCLK is 90 MHz. Divide HCLK by 2 to achieve this clock rate. STCCLKDIV[26:24] register in the secondary system module frame at location 0xFFFFE108 is used.  
STCCLKDIV[26:24] = 1
2. Clear CPU RST status bit in the System Exception Status Register in the system module.  
SYSESR[5] = 1
3. Configure the test interval count in STC module.  
STCGCR0[31:16] = 24
4. Configure self-test run time out counter preload register.  
STCTPR[31:0] = 0xFFFFFFFF
5. Enable CPU self-test.  
STCGCR1[3:0] = 0xA;
6. Perform a context save of CPU state and configuration registers that get reset on CPU reset.
7. Put the CPU in idle mode by executing the CPU idle instruction.  
**asm(" WFI")**
8. Upon CPU reset, verify the CPU RST status bit in the System Exception Status Register is set. This also verifies that no other resets occurred during the self-test.  
SYSESR[5] == 1
9. Check the STCGSTAT register for the self-test status.  
Check TEST\_DONE bit before evaluating TEST\_FAIL bit.

If TEST\_DONE = 0 the self-test is not completed. restart the STC test by going to Step 5.

If (TEST\_DONE = 1 and TEST\_FAIL = 1) the self-test is completed and Failed.

- Read STC Fail Status Register STCFSTAT[2:0] to identify the type of Failure (Timeout, CPU1 fail, CPU2 fail).

In case there is no failure (TEST\_DONE = 1 and TEST\_FAIL = 0), the CPU self-test is completed successfully.

- Recover the CPU status, configuration registers and continue the application software.

## CPU Compare Module for Cortex™-R4F (CCM-R4F)

This chapter describes the CPU compare module for Cortex-R4F (CCM-R4F). This device implements two instances of the Cortex-R4F CPU which are running in lock step to detect faults which may result in unsafe operating conditions. The CCM-R4F detects faults and signals them to an error signaling module (ESM).

---

**NOTE:** In general, R4F is used when referencing the Cortex CPU used in the Hercules family of devices; however, the floating-point functionality is a device-specific option and may not be included in some devices. Consult your device-specific datasheet to determine which core is included on your specific device being used.

## 9.1 Main Features

Safety-critical applications require run-time detection of faults in the Central Processing Unit (CPU). For this purpose, the CPU Compare Module for Cortex-R4F (CCM-R4F) compares the core compare bus outputs of two Cortex-R4F CPUs running in a 1oo1D (one-out-of-one, with diagnostics) lockstep configuration. Any difference in the core compare bus outputs of the CPUs is flagged as an error. For diagnostic purposes, the CCM-R4F also incorporates a self-test capability to allow for boot time checking of hardware faults within the CCM-R4F itself.

The main features of the CCM-R4F are:

- run-time detection of faults
- self-test capability
- error forcing capability

## 9.2 Block Diagram

Figure 9-1 shows the interconnection diagram of the CCM-R4F with the two Cortex-R4F CPUs. The core compare bus outputs of the CPUs are compared in the CCM-R4F. To avoid common mode impacts, the signals of the CPUs to be compared are temporally diverse. The output signals of the master CPU are delayed 2 cycles while the input signals of checker CPU are delayed 2 cycles.

**Figure 9-1. Block Diagram**

## 9.3 Module Operation

The CCM-R4F compares the core compare bus outputs of the master and checker Cortex-R4F CPUs on the microcontroller and signals an error on any mismatch. This comparison is started 6 CPU clock cycles after the CPU comes out of reset to ensure that CPU output signals have propagated to a known value after reset. Once comparison is started, the CCM module continues to monitor the outputs of two CPUs without any software intervention. Upon an error software needs to handle it.

The CCM-R4F can run in one of the following four operating modes:

1. 1001D lock step
2. self-test
3. error forcing
4. self-test error forcing

The operating mode can be selected by writing a dedicated key to the key register (MKEY).

### 9.3.1 1001D Lock Step Mode

This is the default mode on start-up.

In lock step mode, the compare bus output signals of both CPUs are compared. A difference in the CPU compare bus outputs is indicated by signalling an error to the ESM which sets the error flag “CCM-R4F - compare”.

---

**NOTE:** The CPU compare error asserts “CCM-R4F self-test error” flag as well. By doing this, the CPU compare error has two paths (“CCM-R4F - compare” and “CCM-R4F self-test error” flag) to the ESM, so that even if one of the paths fails, the error is still propagated to the ESM.

---

Not all internal registers of the Cortex R4F CPU have fixed values upon reset. To avoid an erroneous CCMR4F compare error, the application software needs to ensure that the CPU registers of both CPUs are initialized with the same values before the registers are used, including function calls where the register values are pushed onto the stack.

### 9.3.2 Self-Test Mode

In self-test mode, the CCM-R4F checks itself for faults. During self-test, the compare error module output signal is deactivated. Any fault detected inside the CCM-R4F will be flagged by ESM error “CCM-R4F - selftest”.

In self-test mode, the CCM-R4F automatically generates test patterns to look for any hardware faults. If a fault is detected, then a self-test error flag is set, a self-test error signal is asserted and sent to the ESM, and the self-test is terminated immediately. If no fault is found during self-test, the self-test complete flag is set. In both cases, the CCM-R4F remains in self-test mode after the test has been terminated or completed, and the application needs to switch the CCM-R4F mode by writing another key to the mode key register (MKEY). During the self-test operation, the compare error signal output to the ESM is inactive irrespective of the compare result.

There are two types of patterns generated by CCM-R4F during self-test mode:

- (i) Compare Match Test
- (ii) Compare Mismatch Test

CCM-R4F first generates Compare Match Test patterns, followed by Compare Mismatch Test patterns. Each test pattern is applied on both CPU signal inputs of the CCM-R4F's compare block and clocked for one cycle. The duration of self-test is 3615 CPU clock cycles (GCLK).

---

**NOTE:** During self-test, both CPUs can execute normally, but the compare logic will not be checking any CPU signals. Also during self-test, only the compare unit logic is tested and not the memory mapped register controls for the CCM-R4F. The self-test is not interruptible.

---

### 9.3.2.1 Compare Match Test

During the Compare Match Test, there are four different test patterns generated to stimulate the CCM-R4F. An identical vector is applied to both input ports at the same time expecting a compare match. These patterns cause the self-test logic to exercise every CPU compare bus output signal in parallel. If the compare unit produces a compare mismatch then the self-test error flag is set, the self-test error signal is generated, and the Compare Match Test is terminated.

The four test patterns used for the Compare Match Test are:

- All 1s on both CPU signal ports
- All 0s on both CPU signal ports
- 0xAs on both CPU signal ports
- 0x5s on both CPU signal ports

These four test patterns will take four clock cycles to complete. illustrates the sequence of Compare Match Test.

**Table 9-1. Compare Match Test Sequence**

| CPU 1 Signal Position |   |   |   |   |   |   |   |   | CPU 2 Signal Position |   |   |   |   |   |   |   |   | Cycle |
|-----------------------|---|---|---|---|---|---|---|---|-----------------------|---|---|---|---|---|---|---|---|-------|
| n:8                   | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | n:8                   | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |       |
| 1s                    | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1s                    | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0     |
| 0s                    | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0s                    | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1     |
| 0xA                   | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 0xA                   | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 2     |
| 0x5                   | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0x5                   | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 3     |

### 9.3.2.2 Compare Mismatch Test

During the Compare Mismatch Test, the number of test patterns is equal to twice the number of CPU output signals to compare in lock step mode. An all 1s vector is applied to the CCM-R4F's CPU1 input port and the same pattern is also applied to the CCM-R4F's CPU2 input port but with one bit flipped starting from signal position 0. The un-equal vector will cause the CCM-R4F to expect a compare mismatch at signal position 0, if the CCM-R4F logic is working correctly. If, however, the CCM-R4F logic reports a compare match, the self-test error flag is set, the self-test error signal is asserted, and the Compare Mismatch Test is terminated.

This Compare Mismatch Test algorithm repeats in a domino fashion with the next signal position flipped while forcing all other signals to logic level 1. This sequence is repeated until every single signal position is verified on both CPU signal ports.

The Compare Mismatch Test is terminated if the CCM-R4F reports a compare match versus the expected compare mismatch. This test ensures that the compare unit is able to detect a mismatch on every CPU signal being compared. [Table 9-2](#) illustrates the sequence of Compare Mismatch Test. There is no error signal is sent to ESM if the expected errors are seen with each pattern.

**Table 9-2. Compare Mismatch Test Sequence**

| CPU 1 Signal Position |       |    |   |   |   |   |   |   |   | CPU 2 Signal Position |   |       |    |   |   |   |   |   |   | Cycle |   |   |      |
|-----------------------|-------|----|---|---|---|---|---|---|---|-----------------------|---|-------|----|---|---|---|---|---|---|-------|---|---|------|
| n                     | n-1:8 |    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0                     | n | n-1:8 |    | 7 | 6 | 5 | 4 | 3 | 2 |       | 1 | 0 |      |
| 1                     | 1     | 1s | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1                     | 1 | 1     | 1s | 1 | 1 | 1 | 1 | 1 | 1 | 1     | 1 | 0 | 0    |

### 9.3.3 Error Forcing Mode

In error forcing mode, a test pattern is applied to the CPU related inputs of the CCM-R4F compare logic to force an error in the compare error output signal of the compare unit. The ESM error flag “CCM-R4F - compare” is expected after the error forcing mode completes. As a side effect, the “CCM-R4F self-test error” flag is also asserted whenever the CPU compare error is asserted.

Error forcing mode is similar to the Compare Mismatch Test operation of self-test mode in which an unequal vector is applied to the CCM-R4F CPU signal ports. The error forcing mode forces the compare mismatch to actually assert the compare error output signal. This ensures that faults in the path between CCM-R4F and ESM is detected.

Only one hardcoded test pattern is applied into CCM-R4F during error forcing mode. A repeated 0x5 pattern is applied to CPU1 signal port of CCM-R4F input while a repeated 0xA pattern is applied to the CPU2 signal port of CCM-R4F input. The error forcing mode takes one cycle to complete. Hence, the failing signature is presented for one clock cycle. After that, the mode is automatically switched to lock step mode. The key register (MKEY) will indicate the lock step key mode once it is switched to lock step mode. During the one cycle required by the error forcing test, the CPU output signals are not compared. User should expect the ESM to trigger a response (report the CCM-R4F fail). If no error is detected by ESM, then a hardware fault is present.

### 9.3.4 Self-Test Error Forcing Mode

In self-test error forcing mode, an error is forced at the self-test error signal. The compare unit is still running in lockstep mode and the key is switched to lockstep after one clock cycle. The ESM error flag “CCM-R4F - selftest” is expected after the self-test error forcing mode completes. Once the expected errors are seen, the application can clean the error through ESM module.

### 9.3.5 Operation During CPU Debug Mode

Certain debug operations place the CPU in a halting debug state where the code execution is halted. Because halting debug events are asynchronous, there is a possibility for the debug requests to cause loss of lockstep. CCM-R4F will disable upon detection of halting debug requests. Core compare error will not be generated and flags will not update. A CPU reset is needed to ensure the CPUs are again in lockstep and will also re-enable the CCM-R4F.

## 9.4 Control Registers

This section describes the CCM-R4F registers. Each register begins on a 32-bit word boundary. The registers support 32-bit, 16-bit and 8-bit accesses.

**Table 9-3. Module Registers**

| Offset     | Acronym | Register Description    | Section                       |
|------------|---------|-------------------------|-------------------------------|

## 10.1 Introduction

This Technical Reference Manual chapter provides an overview of the oscillator and PLL clock source paths for the device.

The oscillator macro will pass a signal driven into the OSCIN pin to clock source 0 which is the default clock source on reset. When a crystal or resonator with appropriate load circuitry is connected to OSCIN and OSCOUT, the oscillator macro drives the crystal/resonator to generate the input waveform. In addition to being directly usable as clock source 0, the oscillator clock is the input to the PLL.

The oscillator frequency is continuously monitored by a dedicated clock detect circuit. If the frequency falls out of a fixed range, the clock detect switches the clock from the oscillator to an internally generated, free-running frequency (from the low power oscillator (LPO)).

The phase lock loop (PLL), a circuit in the microcontroller, is used to multiply the input frequency to some higher (device operation) frequency. This frequency synthesis is useful for generating higher frequencies than can be conveniently achieved with an external crystal or resonator. Additionally, the PLL allows the flexibility to be able to synthesize one of multiple frequency options from a given crystal or resonator.

Frequency modulation can be superimposed on the synthesized frequency. The modulation provides a means to reduce the impact of electromagnetic radiation from the device; this reduction in measured radiation can be useful in sensitive applications.

### 10.1.1 Features

The main features of the source clock path are:

- The oscillator may drive a crystal/resonator or be driven from an external source
- The clock detect provides continuous monitoring of the oscillator frequency and provides an automatic switch over to a free-running clock in case of oscillator failure.
- The FM-PLL module can be operated in either modulation or non-modulation mode.
- The phase-frequency detector assures lock to the fundamental reference frequency.

- $$f_{PLL} = \frac{f_{OSCIN}}{NR} \frac{NF}{OD \times R}$$
 (2)
  - Configurable prescale divider (NR) for the input clock
  - Configurable multiplier (NF)
  - Configurable postscale dividers (OD, R)
- The PLL may be used with modulation enabled.
  - Configurable modulation frequency (NS)
  - Configurable modulation depth (NV)
- The slip control circuitry provides flexible response to a PLL failure (slip) including reset or automatic switch over to oscillator.

## 10.2 Quick Start

The purpose of this section is to provide an overview of how to configure the oscillator and PLL clock paths on power-up. More detailed descriptions are presented in later sections. [Figure 10-1](#) shows the oscillator and PLL clock paths.

**Figure 10-1. Clock Path From Oscillator Through PLL To Device**

While power-on reset is asserted (low), the oscillator and low power oscillator (LPO) are enabled and start-up by default. After power-on reset is released to a high level, the clock detect circuit (CLKDET) begins to monitor the oscillator. If the oscillator is within a valid range, the oscillator becomes the default clock for the device as it exits reset; if the oscillator is not within a valid range, the clock detect selects the high-frequency low power oscillator as the default clock for the device.

The low power oscillator has a wide frequency range which also creates a large valid window for the clock detect; in order to refine the clock detect window, the low power oscillator can be trimmed. The initial trim value is stored in one-time programmable section of the flash memory, address 0xF008\_01B4. Bits 31:16 of this word contain a 16 bit value that may be programmed into LPOMONCTL(15:0) in order to initialize the trim for both HF LPO and LF LPO. Software should read the initial trim values from flash and write them to the control register.

The PLL is disabled by default on power-up. The PLL control registers (PLLCTL1 and PLLCTL2) must be configured to set the desired output frequency. Then, the system PLL may be enabled (CSDISCLR.1). Similarly, the second PLL must be configured in PLLCTL3 and enabled (CSDISCLR.6). Each PLL has a valid bit that indicates the PLL is locked (CLKSRnV bit in the Clock Source Valid Status Register (CSVSTAT) of the System and Peripheral Control Registers).

Prior to selecting the PLL clock as the source for a clock domain (for example, GCLK, HCLK, ACLKV1), the domain and modules on the domain must be configured to accept the new frequency. An example of a module that should be configured prior to selecting the PLL as clock source for GCLK and HCLK is the memory wrapper to insure that access times are maintained correctly.

## 10.3 Oscillator

The clock generation path through the PLL begins with the oscillator. The oscillator consists of three separate pads -- OSCIN, OSCOUT, and Kelvin\_GND (see [Figure 10-2](#)).

**Figure 10-2. Clock Generation Path**

The oscillator is responsible for two independent functions:

1. The oscillator is responsible for generating positive feedback in the external crystal/resonator with appropriate load and tank circuitry. At start-up, the oscillator amplifies random noise. The external circuitry acts like a band-pass and selects the crystal/resonator frequency to provide as positive feedback into the amplifier. The positive feedback increases the amplitude of the output waveform into the crystal/resonator (and the load circuitry), and the voltage waveform shows an envelope of increasing amplitude. The oscillator can drive a crystal frequency that is within the data sheet range  $t_{c(OSC)}$ .

Looking at the input waveform into OSCIN, the voltage waveform is an AC-coupled, filtered version of the OSCOUT waveform. The band-pass functionality of the crystal/resonator removes any distortion that might exist on the OSCOUT waveform, leaving a sinusoidal input waveform.

---

**NOTE: Vendor Validation of Resonators/Crystals**

The crystal is a very tight bandpass filter while a resonator is a somewhat wider bandpass. The load circuitry pulls the center frequency of the bandpass.

Texas Instruments strongly encourages each customer to submit samples of the device to the resonator/crystal vendor for validation. The vendor is equipped to determine what load capacitances will best tune their resonator/crystal to the microcontroller device for optimum start-up and operation over temperature and voltage extremes. The vendor also factors in margins for variations in the microcontroller process.

---

2. The oscillator is also responsible for squaring-up the input waveform. This squaring-up converts the sinusoid into a square wave at the core logic levels. The input path limits the input frequency range as a low-pass filter with a cutoff frequency.

The oscillator has a frequency range that is determined by the driving capability of external crystals/resonators (feedback path). If a clock is driven directly into the oscillator, then the feedback path is not relevant and the frequency range is determined solely by the forward path (which typically allows a higher frequency); the device can support inputs within the data sheet range  $t_{c(OSC\_Sqr)}$ .

### 10.3.1 Oscillator Implementation

The oscillator operates at 3.3V and uses a constant current source to drive current onto the OSCOUT node. An internal transistor shunts the current (and current from the external circuitry) to GND. This current steering drives the voltage waveform on OSCOUT.

**Figure 10-3. Oscillator Implementation**

### 10.3.2 Oscillator Enable

The oscillator is enabled asynchronously when nPORRST is low.

The oscillator is enabled by clearing bit 0 in the Clock Source Disable Register (CSDIS) or setting bit 0 in the Clock Source Disable Clear Register (CSDISCLR) of the System and Peripheral Control Registers. The bit sends a start signal to the oscillator. Bit 0 of CSDIS is cleared to 0 by default on a system or power-on reset so that the oscillator starts-up by default. After the oscillator swings at a high-enough amplitude to pass an input clock into the core domain and nPORRST is released, 1024 oscillator periods are counted before setting the CLKSR0V bit in the Clock Source Valid Status Register (CSVSTAT) of the System and Peripheral Control Registers. The oscillator generates clock source 0 in the global clock module (GCM).

### 10.3.3 Oscillator Disable

The clock sources (for example, OSC, PLL) are disabled by setting the appropriate bit in the Clock Source Disable Register (CSDIS) or setting the appropriate bit in the Clock Source Disable Set Register (CSDISSET) of the System and Peripheral Control Registers. These bits *allow* the clock source to disable but do not force the behavior until the clock is no longer used as the source for a clock domain (for example, GCLK, VCLK, VCLK2, RTICLK). The CLKSR0V bit in the Clock Source Valid Status Register (CSVSTAT), of the System and Peripheral Control Registers, is cleared after clock disable is asserted (which occurs after all clock domains are stopped).

The oscillator disable signal places the oscillator into a low power state, disconnects the feedback (bias) resistor between OSCIN and OSCOUT, and OSCIN is grounded.

## 10.4 Low Power Oscillator and Clock Detect (LPOCLKDET)

The Low Power Oscillator (LPO) is comprised of two oscillators -- HF LPO and LF LPO -- in a single macro. The low power oscillator and clock detect (LPOCLKDET) uses a relaxation oscillator to generate an internal clock whose frequency is NOT tightly controlled. This frequency is used to monitor the oscillator input frequency and is also available as an independent clock source in the GCM.

The LPO produces two frequencies:

- High-frequency low power oscillator (HF LPO) with a nominal frequency of 10MHz and a range from 5.6MHz to 22.6MHz; the HF LPO generates clock source 5 in the GCM.
- Low-frequency low power oscillator (LF LPO) with a nominal frequency of 100KHz; the LF LPO generates clock source 4 in the GCM.

A single current source drives current onto a capacitor; when the voltage on the capacitor exceeds some threshold, the clock toggles. The LPO uses a single current source and the two different comparators to generate the HF LPO and LF LPO frequencies. The LPO is controlled by 4 different bit fields -- CSDIS.(5:4), HFTRIM(4:0), LFTRIM(4:0), and BIASEN.

- CSDIS.5 enables/disables the comparator that generates HF LPO.
- CSDIS.4 enables/disables the comparator that generates LF LPO.
- The HF TRIM and LF TRIM bit fields vary the current into the comparator to independently trim the HF LPO and LF LPO frequencies (see ).
- BIAS ENABLE (LPOMONCTL.24) enables/disables the current source which drives the LPO.

### 10.4.1 Clock Detect

The LPO HF clock frequency is typically near 10MHz but ranges from 5.6MHz to 22.6MHz. The clock detect establishes a window for the oscillator by:

|                                   |                                     |
|-----------------------------------|-------------------------------------|
| $OSCIN > HF\ LPO_{min} / 4$       | $OSCIN / 4 < HF\ LPO_{max}$         |
| $OSCIN > 5.6[MHz] / 4 = 1.4[MHz]$ | $OSCIN < 4 \times 22.6 = 90.4[MHz]$ |

The clock detect circuit works by checking for a rising edge on one clock (oscillator or HF LPO) between rising edges of the other clock. The result is that in addition to flagging incorrect, repeating frequencies, the circuit also fails due to transient conditions.

The low end of the clock detect window ignores a transient low phase of at least 12 HF LPO cycles.

---

**NOTE: Clock Detection of Oscillator MUST be Disabled Before Disabling HF LPO**

The HF LPO frequency is the comparison frequency for the oscillator. The clock detection must be disabled prior to disabling the HF LPO frequency.

If the clock detection is NOT disabled prior to disabling the HF LPO, the clock detect circuitry will fail the oscillator as too fast (compared to the non-existent HF LPO). The clock detect circuitry will switch to the non-existent clock, leaving the device without a valid clock.

---

### 10.4.2 Behavior on Oscillator Failure

If the oscillator frequency fails, the clock detects supplies:

- the HF LPO clock to GCM clock source 0 instead of the oscillator
- the HF LPO clock to GCM clock source 1 instead of the PLL

The HF LPO signal will be available as three different clock sources:

- GCM clock source 0 (replacing the oscillator)
- GCM clock source 1 (replacing the PLL)
- GCM clock source 4 as HF LPO

The automatic switch-over from oscillator to HF LPO allows the application to execute at a reduced frequency and respond to a problem with the external crystal/resonator. During and after an oscillator failure, the oscillator CLKSRnV bit in the Clock Source Valid Status Register (CSVSTAT), of the System and Peripheral Control Registers, is set along with the OSCFAIL flag in the Global Status Register (GLBSTAT), of the System and Peripheral Control Registers.

It is useful to explicitly change the GHVSRG register, defining the current clock source for GCLK/HCLK/VCLK domains, to the HF LPO after an oscillator failure.

When reset on oscillator failure is set, PLLCTL1.23 (ROF), the device responds to an oscillator failure by generating a device reset.

### 10.4.3 Recovery from Oscillator Failure

If the oscillator fails, the clock detect switches the HF LPO frequency onto the oscillator source into the GCM. The OSCFAIL flag in the Global Status Register (GLBSTAT), of the System and Peripheral Control Registers, is also set.

The oscillator may be re-enabled (though if the failure was caused by a hard-fault, the re-enable will fail) through the following procedure:

1. Switch all clock domains from the oscillator to the HF LPO (for example, GHVSRG uses HF LPO, ACLKV uses HF LPO or VCLK,...).
2. If the PLL is used, disable the PLL by setting the appropriate bit in the Clock Source Disable Set Register (CSDISSET) of the System and Peripheral Control Registers.
3. Disable the oscillator by setting the appropriate bit in the Clock Source Disable Set Register (CSDISSET). This action resets the clock detect and allows the oscillator to propagate through GCM clock source 0.
4. Re-enable the oscillator by setting the appropriate bit in the Clock Source Disable Clear Register (CSDISCLR) of the System and Peripheral Control Registers.
5. Clear the OSCFAIL flag in the Global Status Register (GLBSTAT) by writing a 1 to the bit. The PLL slip bits may also be set on an oscillator failure. These can also be cleared.
6. Switch the clock domains back to the oscillator.
7. Re-enable the PLL by setting the appropriate bit in the Clock Source Disable Clear Register (CSDISCLR).

---

**NOTE: Clock Re-Enable Procedure Will Fail If Caused by a Hard Failure**

Although it is possible to re-enable the oscillator after a failure, if the oscillator failure was caused by a hard fault (for example, disconnected crystal/resonator terminal), the re-enable process will fail.

---

### 10.4.4 LPOCLKDET Enable

The LPO is enabled by default while nPORRST is low. During this time, the current source initializes, holding the relaxation oscillator in reset until initialized. After the current source releases the HF LPO and the LF LPO, these clock frequencies slew to their final frequencies; the final frequency may be achieved while nPORRST is active or after its release. After, nPORRST is released, the HF LPO Valid signal is set 32 HF LPO clock cycles later.

The clock detect is enabled once the oscillator and HF LPO are valid. Because an oscillator failure could occur from reset, the clock detect logic must provide an override path. If the HF LPO is valid and the oscillator is not valid, the clock detect circuitry will become active (overriding the oscillator invalid signal) after 16K LF LPO cycles (about 200ms).

## 10.4.5 LPOCLKDET Disable

### 10.4.5.1 Disable Clock Detect

It is possible to disable the clock detect circuitry. For protection, this clock detect disable employs a 2-bit key:

- RANGE DET ENA SSET (CLKTEST.24) must be set to 1
- RANGE DET CTRL (CLKTEST.25) must be cleared to 0

In this case, the LPO HF and LF clocks are still active but the clock detect circuitry is disabled. The clock detect unconditionally switches GCM\_CLK\_SRC(0) back to the oscillator so care should be taken to insure that the oscillator is good before disabling the clock detect circuitry.

### 10.4.5.2 Disable LPO HF and LF clocks

The LPO may be disabled by holding the relaxation oscillator clocks (HF and LF) in reset. The clock detect must be disabled, and any clock domains using either HF or LF clocks must be switched to a different clock source. The LPO HF clock is reset by setting CSDIS.5; CSDISSET.5 is an easy way to set specific bits without disturbing the rest of the register. The HF LPO clock disables several HF LPO cycles after CSDIS is set.

Similarly, the LPO LF clock is reset by setting CSDIS.4, and in a similar way CSDISSET.4 can set the specific CSDIS register bit without using a read-modify-write construction. The LF LPO disables several LF LPO cycles after CSDIS is set.

Restarting the LPO clocks from this condition is fast and is known as a warm re-start. The CSDISCLR register allows the user to clear CSDIS bits without using a read-modify-write code-construct.

### 10.4.5.3 Disable LPO Current Bias

The LPO current source may be disabled after the clock detect is disabled and HF and LF clock sources are disabled. Turning off this current source places the LPOCLKDET into its lowest power configuration. The bias may be disabled by clearing the BIAS ENABLE bit (LPOMONCTL.24).

Restarting the LPO when the bias current has been disabled requires the current source to initialize first and is, therefore slower than a warm re-start; re-enabling the LPO from this condition is known as a warm re-start (similar to what happens during nPORRST active).

## 10.4.6 Trimming the HF LPO Oscillator

The HF LPO range varies considerably around 10MHz from device to device. In order to provide tighter monitoring of the crystal/resonator, it is useful to trim the oscillator. During device test, a trim value is written into the one-time programmable section of the flash memory (OTP), address 0xF008\_01B4. Bits 31:16 of this OTP word contain a 16 bit value that may be programmed into LPOMONCTL(15:0) in order to initialize the trim for both HF LPO and LF LPO.

When trimming the HF LPO, it is recommended to step the trim value so as not to make a large change to any TRIM setting.

After the initial trim, further trimming may be done in LPOMONCTL, using the dual clock compare module (see [Chapter 11](#)) in order to determine the resultant frequency. This module allows for comparison of two clock frequencies. Once the HF LPO is determined to be in-range with the initial HFTRIM setting from the OTP, the crystal oscillator may be used as a reference against which the HF LPO and LF LPO may be further adjusted.

## 10.5 PLL

The following bit fields from PLLCTL1 and PLLCTL2 configure the PLL:

- REFCLKDIV[5:0]
- PLLMUL[15:0]
- ODPLL[2:0]
- PLLDIV[4:0]
- SPR\_AMOUNT[8:0]
- SPREADINGRATE[8:0]
- FMENA

The PLL is responsible for synthesizing an output frequency from the input clock (from the oscillator); [Figure 10-4](#) shows a simple block diagram of the PLL. The FM-PLL divides the reference input for a lower frequency input into the PLL ( $f_{\text{INTCLK}} = f_{\text{CLKIN}}/\text{NR}$ ). The PLL multiplies this internal frequency by NF to get the VCO output clock frequency ( $f_{\text{Output CLK}} = f_{\text{INTCLK}} \times \text{NF}$ ). The PLL output is subsequently divided by two prescale values (OD and R). The value of OD is an integer from 1-8 and R is an integer from 1–32. This output clock, PLL CLK, sources GCM clock source 1. Valid frequencies are shown in [Table 10-1](#) while [Table 10-2](#) shows how that encoding is generated from the PLL bit fields.

[ $f_{\text{(post\_ODCLK)}}$  and  $f_{\text{(HCLK)}}$  are data sheet parameters.]

**Table 10-1. Valid Frequency Ranges for PLL**

|                         | Frequency Limit                |
|-------------------------|--------------------------------|
| $f_{\text{CLKIN}}$      | $f_{\text{(OSC\_Sqr)}}$        |
| $f_{\text{INTCLK}}$     | 1MHz - $f_{\text{(OSC\_Sqr)}}$ |
| $f_{\text{Output CLK}}$ | 150MHz - 550MHz                |
| $f_{\text{post-ODCLK}}$ | $f_{\text{(post\_ODCLK)}}$     |
| $f_{\text{PLL CLK}}$    | $f_{\text{(HCLK)}}$            |

**Figure 10-4. Operation of the FM-PLL module**

**Table 10-2. PLL Value Encoding**

|           | PLL                                                                         |     |
|-----------|-----------------------------------------------------------------------------|-----|
| <b>NR</b> | $NR = REFCLKDIV[5...0] + 1$                                                 | (3) |
| <b>NF</b> | Non-modulated:<br>$NF = \frac{(PLLMUL[15...0] + 1 \ll 8)}{256}$             | (4) |
|           | Modulated:<br>$NF = \frac{(PLLMUL[15...0] + MULMOD[8...0] + 1 \ll 8)}{256}$ | (5) |
| <b>NV</b> | $NV = \frac{(SPRAMOUNT[8...0] + 1)}{2048}$                                  | (6) |
| <b>NS</b> | $NS = SPRRATE[8...0] + 1$                                                   | (7) |
| <b>OD</b> | $OD = ODPLL[2...0] + 1$                                                     | (8) |

**NOTE:** ODPLL change should occur prior to enabling asynchronous clock domains

Since changing the ODPLL bit-field causes the PLL CLK to be gated, these changes to ODPLL should be completed before configuring a clock domain for an asynchronous clock source. Some clock domains (for example, RTICLK, VCLK2) require a frequency relationship to the VCLK.

$$f_{VCLK} \geq 3 \times \frac{f_{RTISRC}}{RTIDIV}$$

If the PLL is clocking VCLK and it is stopped for some cycles, then the frequency relationship is temporarily violated.

Many asynchronous domains require frequency relationships between VCLK and the asynchronous domain. Therefore, if the PLL clock is the source for GCLK, HCLK and VCLK, then the gating produces a short-term change in the PLL clock frequency (and hence also the VCLK frequency). As such, this frequency change could violate the requirements for an asynchronous clock domain.

### 10.5.1 Modulation

Optionally, the frequency can be modulated, that is, a controlled jitter is introduced onto the baseline frequency of the PLL. This modulation mechanism is not shown in Figure 10-4. When the PLL is used in the modulating mode, the programmable modulation block varies the PLL frequency from the baseline frequency ( $f_{baseline} = (f_{CLKIN}/NR) \times NF/(OD \times R)$ ) to  $f_{baseline} \times (1 - 2 \times \text{Depth})$  in a period defined by  $1/f_s$ ; the modulation waveform is triangular and should be enabled after lock.

The modulation is digital and the spreading profile is triangular, down-spread which implies:

- the modulation waveform is composed of a series of frequency steps.
- the modulation frequency and modulation depth are both well controlled due to their digital character.
- the average frequency during modulation is lower than the average frequency prior to enabling modulation. The depth of modulation, however, sets the new average frequency.
- the modulation frequency must be selected slower than the loop bandwidth. From a practical perspective, NS should be near 20.

The modulation fields have a simple geometric meaning:

- the modulation step size is:

$$\frac{NV}{NF} \times f_{OutputCLK} \quad (9)$$

- the number of steps per modulation period is  $2 \times NS$
- the modulation depth is given by:

$$\Delta f = \frac{NS}{2} \times \frac{NV}{NF} \times f_{OutputCLK}$$

$$Depth [\%] = \frac{NS}{2} \times \frac{NV}{NF} \quad (10)$$

- the modulation frequency is:

$$T_{mod} = \frac{f_{osc}}{2 \times NR \times NS} \quad (11)$$

- MULMOD minimizes frequency offset when programmed as:

$$\frac{(SPRAMOUNT[8...0] + 1)(SPRRATE[8...0] + 1)}{16} \quad (12)$$

---

**NOTE: Modulation should be enabled after Lock**

Enable modulation after the lock is completed.

---

### 10.5.2 PLL Output Control

The outputs from the PLL are the output clock, slip signals, and VALID.

- RFSLIP -- the RFSLIP signal indicates that the Output CLK is running *too fast* relative to INTCLK and sets a RFSLIP status flag in the Global Status Register (GLBSTAT) register, of the System and Peripheral Control Registers, if the slip signal is active during normal PLL operation; the RFSLIP flag is masked off while the PLL is not active and during the PLL's lock period.
- FBSLIP -- the FBSLIP signal indicates that the Output CLK is running *too slow* relative to INTCLK and sets a FBSLIP status flag in the Global Status Register (GLBSTAT) register, of the System and Peripheral Control Registers, if the slip signal is active during normal PLL operation; the FBSLIP flag is masked off while the PLL is not active and during the PLL's lock period.
- PLL Slip -- Logical-OR of the two PLL slip signals. Typically this signal is used to generate a consolidated slip signal to the device (for example, error logic or exception generation). Also used to gate VALID.

---

**NOTE: Clearing Slip Bits**

In order to clear any of the slip bits, it is necessary to disable the PLL first.

---

- **VALID** -- is driven based upon whether the output clock, PLL CLK, is gated or not. However, the VALID signal is dependent upon the PLL Slip signals so that VALID cannot be set if either slip signal is active.
- **PLL Clock** -- The PLL output clock runs at the programmed frequency. When enabled, it takes some time to acquire the programmed frequency (see [Section 10.5.2.1](#)). Similarly, the disable has some timing/constraints (see [Section 10.5.2.2](#)).

### 10.5.2.1 PLL Enable

After setting the PLL control registers, the clock source is enabled by clearing the appropriate bit in the Clock Source Disable Register (CSDIS) or setting the appropriate bit in the Clock Source Disable Clear Register (CSDISCLR) of the System and Peripheral Control Registers. The bit sends a signal to the PLL that starts the process of enabling the PLL.

1. The PLL checks to make sure that the oscillator is ON. If not, it turns the oscillator ON.
2. The PLL begins a locking process in which the PLL slews from a starting frequency point to the programmed frequency. During this lock period, the PLL slip signals are typically active, and the PLL masks off the signals during this phase. The lock phase takes the following length of time:

|                                 | <b>LPOMONCTRL.16 = 0 (OSCIN &lt;= 20MHz)<br/>Counters clocked by OSCIN /1</b>                       | <b>LPOMONCTRL.16 = 1 (OSCIN &gt; 20MHz)<br/>Counters clocked by OSCIN /4</b>                                 |
|---------------------------------|-----------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Lock</b>                     | $T_{\text{Lock}} = (127 \times T_{\text{OSCIN}}) + (1024 \times \text{NR} \times T_{\text{OSCIN}})$ | $T_{\text{Lock}} = (127 \times 4 \times T_{\text{OSCIN}}) + (1024 \times \text{NR} \times T_{\text{OSCIN}})$ |
| <b>Enable clocks after lock</b> | $T_{\text{Enable}} = 6 \times T_{\text{OSCIN}}$                                                     | $T_{\text{Enable}} = 18 \times T_{\text{OSCIN}}$                                                             |

3. After the lock phase is complete (when lock counters expire), the PLL releases the slip signals to the system.
4. Then, after the slip signals are released and a delay to enable the clocks, the clock is released to the system and the appropriate CLKSRnV bit for the PLL is set in the Clock Source Valid Status Register (CSVSTAT) of the System and Peripheral Control Registers.

### 10.5.2.2 PLL Disable

The clock sources (for example, OSC, PLL) are disabled by setting the appropriate bit in the Clock Source Disable Register (CSDIS) or setting the appropriate bit in the Clock Source Disable Set Register (CSDISSET) of the System and Peripheral Control Registers. These bit *allow* the clock to disable but do not force the behavior until the clock is no longer used as the source for a clock domain (for example, GCLK, VCLK, VCLK2, RTICK).

The PLL receives a signal to disable after the clock is no longer used by any clock domain. Within the PLL, the clock is disabled and the appropriate CLKSRnV bit for the PLL in the Clock Source Valid Status Register (CSVSTAT), of the System and Peripheral Control Registers, becomes inactive. Then the PLL is placed into a low power state after the following length of time:

|                                  | <b>LPOMONCTRL.16 = 0<br/>Counters clocked by OSCIN /1</b> | <b>LPOMONCTRL.16 = 1<br/>Counters clocked by OSCIN /4</b> |
|----------------------------------|-----------------------------------------------------------|-----------------------------------------------------------|
| <b>Disable clocks after lock</b> | $T_{\text{Enable}} = 150 \times T_{\text{OSCIN}}$         | $T_{\text{Enable}} = 582 \times T_{\text{OSCIN}}$         |

### 10.5.2.3 OD-divider Change

The PLL gates the clock if the ODPLL bit-field is changed while the PLL is active. The output clock from the PLL is gated for 3 or 12 OSCIN clock cycles. As the post-ODCLK is gated in the low phase, the output clock to the device -- PLL CLK -- may be gated in a high or low phase though the transition is always glitchless.

|                     | <b>LPOMONCTRL.16 = 0</b><br><b>Counters clocked by OSCIN /1</b> | <b>LPOMONCTRL.16 = 1</b><br><b>Counters clocked by OSCIN /4</b> |
|---------------------|-----------------------------------------------------------------|-----------------------------------------------------------------|
| <b>Change ODPLL</b> | $T_{ODPLL} = 3 \times T_{OSCIN}$                                | $T_{ODPLL} = 3 \times 4 \times T_{OSCIN}$                       |

**NOTE: ODPLL change should occur prior to enabling asynchronous clock domains**

Since changing the ODPLL bit-field causes the PLL CLK to be gated, these changes to ODPLL should be completed before configuring a clock domain for an asynchronous clock source. Some clock domains (for example, RTICLK, VCLK2) require a frequency relationship to the VCLK.

$$f_{VCLK} \geq 3 \times \frac{f_{RTISRC}}{RTIDIV}$$

If the PLL is clocking VCLK and it is stopped for some cycles, then the frequency relationship is temporarily violated.

Many asynchronous domains require frequency relationships between VCLK and the asynchronous domain. Therefore, if the PLL clock is the source for GCLK, HCLK and VCLK, then the gating produces a short-term change in the PLL clock frequency (and hence also the VCLK frequency). As such, this frequency change could violate the requirements for an asynchronous clock domain.

#### 10.5.2.4 Changing the PLL Operating Point While the PLL is Active

Once the valid bit (CLKSRnV bit in the Clock Source Valid Status Register (CSVSTAT) of the System and Peripheral Control Registers) is set, software may change values to the PLL. If the change of values results in a small percentage change to the VCO frequency ( $\Delta f_{OutputCLK} < 0.1 \times f_{OutputCLK}$ ), then these changes can be done on-the-fly. In this mode, the values are updated into the PLL synchronously, and the PLL re-locks to the new value without gating the clocks or the slip bits. If the operating point change is too large, then the slip bits will be set.

Conversely, if the changes to the VCO frequency are large, then the PLL should be disabled prior to changing the values. Typically, any change to the REFCLKDIV field or large changes to the PLLMUL field in the PLL Control Register 1 (PLLCTL1) of the System and Peripheral Control Registers requires a complete disable-and-relock strategy.

#### 10.5.2.5 Summary of PLL Timings

In addition to controlling the lock period and disabling the clock during an ODPLL change, the PLL also generates reset delays. When power-on reset is released (nPORRST 0 --> 1), that release is delayed by 1024 OSCIN cycles so that it is released at the same time that the oscillator valid is asserted. The system reset release is delayed by an additional 8 oscillator clock cycles.

**Table 10-3. State Machine Timings**

|                                  | <b>LPOMONCTRL.16 = 0</b><br><b>Counters clocked by OSCIN /1</b>         | <b>LPOMONCTRL.16 = 1</b><br><b>Counters clocked by OSCIN /4</b>                  |
|----------------------------------|-------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| <b>nPORRST delay</b>             | $T_{nPORRST} = 1024 \times T_{OSCIN}$                                   | $T_{nPORRST} = 1024 \times T_{OSCIN}$                                            |
| <b>nRST delay</b>                | $T_{nRST} = 1032 \times T_{OSCIN}$                                      | $T_{nRST} = 1032 \times T_{OSCIN}$                                               |
| <b>OSC valid</b>                 | $T_{OSCVALID} = 1024 \times T_{OSCIN}$                                  | $T_{OSCVALID} = 1024 \times T_{OSCIN}$                                           |
| <b>Lock</b>                      | $T_{Lock} = (127 \times T_{OSCIN}) + (1024 \times NR \times T_{OSCIN})$ | $T_{Lock} = (127 \times 4 \times T_{OSCIN}) + (1024 \times NR \times T_{OSCIN})$ |
| <b>Enable clocks after lock</b>  | $T_{Enable} = 6 \times T_{OSCIN}$                                       | $T_{Enable} = 18 \times T_{OSCIN}$                                               |
| <b>Disable clocks after lock</b> | $T_{Enable} = 150 \times T_{OSCIN}$                                     | $T_{Enable} = 582 \times T_{OSCIN}$                                              |
| <b>Change ODPLL</b>              | $T_{ODPLL} = 3 \times T_{OSCIN}$                                        | $T_{ODPLL} = 3 \times 4 \times T_{OSCIN}$                                        |

### 10.5.3 Behavior on PLL Fail

The PLL allows flexible response to a PLL failure (slip). Like the oscillator, the PLL clock is configured by default to automatically switch-over to the oscillator in case of a PLL slip. (In this case, the oscillator sources GCM clock source 1 as well as GCM clock source 0. Also, if the oscillator fails, LPO HF is sourced to both GCM clock sources 0 and 1.)

The PLL slip outputs indicate that the PLL is running either too fast or too slow. These error output toggle when the PLL is locking and when the PLL is disabling. The PLL blocks these slip outputs during these times, leaving them active only while the PLL is active.

A slip after the PLL has locked and while it is active is an indication of a PLL failure. The PLL provides slip-filtering which enhances the flexibility of the PLL's response to failure. The slip-filtering circuit samples the slip based on HF LPO. The filter defines the number of consecutive HF LPO cycles for which the slip signal must be active before the slip is recognized. This slip is latched in the RFSLIP and FBSLIP status flags in the Global Status Register (GLBSTAT) register of the System and Peripheral Control Registers.

The PLL may enable/disable the automatic switch over as well as the error signaling; if the error signaling is enabled, a PLL slip may be configured to generate a reset. The automatic switch-over and suppression of the error signals are controlled by the bypass on slip bit field -- BPOS[1:0] (PLLCTL1.(30:29)). When BPOS[1:0] is disabled (BPOS[1:0] = 10b):

- automatic response to the PLL slip is prevented
- ESM/exception is NOT generated
- reset on slip is not generated regardless of the state of the ROS bit
- status bits are set on a PLL slip independent of BPOS[1:0]

When BPOS[1:0] is enabled (BPOS[1:0] = 00b OR 01b OR 11b):

- PLL slip causes the clock source into GCM clock source 1 to shift from the PLL to the oscillator
- ESM/exception is generated
- reset on slip is generated if ROS is set

The effect of BPOS[1:0] on the system is shown in [Figure 10-5](#).

**Figure 10-5. PLL Slip Detection and Reset/Bypass Block Diagram**

### 10.5.4 Recovery from a PLL Failure

If PLL1 fails, the PLL's slip causes the clock source into GCM clock source 1 to shift from the PLL to the oscillator. The RFSLIP or FBSLIP status flags in the Global Status Register (GLBSTAT) register of the System and Peripheral Control Registers is also set. PLL1 may be re-enabled (though if the failure was caused by a hard-fault, the re-enable will fail) through the following procedure:

1. Switch all clock domains from PLL1 to the oscillator (for example, GHVSR uses oscillator, ACLKV uses oscillator or VCLK,...).
2. Disable PLL1 with CSDISSET. This action disables the PLL and causes the slip signal to no longer be driven. Valid is not released until the slip is cleared.
3. Clear the RFSLIP or FBSLIP status flags in the Global Status Register (GLBSTAT) register of the System and Peripheral Control Registers by writing a 1 to the bit.
4. Re-enable PLL1 with CSDISCLR.
5. Switch the clock domains back to PLL1.

If PLL2 fails, the PLL's slip causes the valid flag to be locked. There is no autonomous change of clock source for PLL2. Neither the RFSLIP or FBSLIP status flags in the Global Status Register (GLBSTAT) register of the System and Peripheral Control Registers is set. PLL2 may be re-enabled in a similar procedure to re-enabling PLL1 (though if the failure was caused by a hard-fault, the re-enable will fail):

1. Switch all clock domains from PLL2 to the oscillator (for example, GHVSR uses oscillator, ACLKV uses oscillator or VCLK,...).
2. Disable PLL2 with CSDISSET. This action disables the PLL and causes the slip signal to no longer be driven. Valid is not released until the slip is cleared.
3. Reset PLL2 Valid by writing a 1 to both RFSLIP and FBSLIP status flags in the Global Status Register (GLBSTAT) register of the System and Peripheral Control Registers (even though they are not set by the slip).
4. Re-enable PLL2 with CSDISCLR.
5. Switch the clock domains back to PLL2.

### 10.5.5 PLL Modulation Depth Measurement

The PLL contains a circuit for estimating the depth of the modulation. The circuit counts clock edges over a fixed window of the modulation waveform (SSW\_CAPTURE\_COUNT in SSWPLL2) and clock edges over the entire waveform (SSW\_CLKOUT\_COUNT in SSWPLL3). The capture ends after a pre-determined number of clock edges in SSW\_CLKOUT\_COUNTER as set in TAP\_COUNTER\_DIS. There are  $2 \times NR$  windows per modulation waveform. The procedure for estimating the modulation depth is:

1. While GCLK is sourced by the oscillator and the PLL is enabled with modulation, configure SSWPLL1 as follows:
  - (a) CAPTURE\_WINDOW\_INDEX is set equal to NR.
  - (b) COUNTER\_RESET is set.
  - (c) TAP\_COUNTER\_DIS is set to disable the measurement after SSW\_CLKOUT\_COUNT captures this number of clocks. The measurement is disabled after the set tap is set AND the modulation cycle ends.
  - (d) Ensure that EXT\_COUNTER\_EN is cleared.
2. Ensure that both SSW\_CAPTURE\_COUNT and SSW\_CLKOUT\_COUNT are cleared (by the COUNTER\_RESET).
3. Set COUNTER\_EN and clear COUNTER\_RESET. This step releases the reset and enables the counter to begin counting.
4. After a wait loop, poll for COUNTER\_READ\_READY to set. After the bit is set, read SSW\_CAPTURE\_COUNT and SSW\_CLKOUT\_COUNT.
5. Compute the modulation depth as:

$$Depth = abs\left(1 - \frac{2 \times NR \times SSW\_CAPTURE\_COUNT}{SSW\_CLKOUT\_COUNT}\right) \quad (13)$$

### 10.5.6 PLL Frequency Measurement Circuit

The same circuit that is used to measure modulation depth is also available to measure the average frequency of the PLL. In this mode, the PLL output (before the R-divider) is captured in SSW\_CLKOUT\_COUNT while the oscillator is captured in SSW\_CAPTURE\_COUNT. The procedure for using the PLL frequency measurement circuit is:

1. While the PLL is enabled, set EXT\_COUNTER\_EN.
2. Set COUNTER\_EN. This bit clears both SSW\_CAPTURE\_COUNT and SSW\_CLKOUT\_COUNT and then immediately enables for counting.
3. Wait for some software delay loop.
4. Clear COUNTER\_EN. Wait for COUNTER\_READ\_READY to set. Read both SSW\_CAPTURE\_COUNT and SSW\_CLKOUT\_COUNT and compute the ratio of PLL multiplication as:

$$\frac{NF}{NR \times OD} = \frac{SSW\_CLKOUT\_COUNT}{SSW\_CAPTURE\_COUNT} \quad (14)$$

5. Note that CAPTURE\_WINDOW\_INDEX, COUNTER\_RESET, TAP\_COUNTER\_DIS are not used in this procedure

### 10.5.7 PLL2

PLL2 drives GCM clock source 6.

The PLL is identical to PLL1, except modulation is disabled on this instance of the PLL. Also, the PLL typically does not clock the system, there is no automatic switch over feature. Any PLL error can be handled by the CPU.

PLL2 is programmed through PLLCTL3.

## 10.6 Control Registers

The clock module has two registers (PLLCTL1 and PLLCTL2) located within the System and Peripheral Control Registers, plus it has four bits located in other System and Peripheral Control Registers.

The FM-PLL is off at power-on. The clock source is enabled by clearing the appropriate bit in the Clock Source Disable Register (CSDIS) or setting the appropriate bit in the Clock Source Disable Clear Register (CSDISCLR) of the System and Peripheral Control Registers. [CSDISCLR and Clock Source Disable Set Register (CSDISSET) also enable/disable the PLL and oscillator (and other clock sources).]

The LPOCLKDET module generates the OSCFAIL flag in the Global Status Register (GLBSTAT), of the System and Peripheral Control Registers, if a problem with the reference oscillator is detected. The slip signals are also registered in the RFSLIP and FBSLIP status flags in the Global Status Register (GLBSTAT) register, of the System and Peripheral Control Registers, in order to indicate the source of a clock failure.

The appropriate CLKSRnV bit for the PLL is set in the Clock Source Valid Status Register (CSVSTAT) of the System and Peripheral Control Registers.

The following sections describe the PLL registers used in the system module. These registers support 8, 16, and 32-bit write accesses. The reset values for these registers are configured so that an input frequency in the range from 5MHz to 20MHz generates a valid clock.

**Table 10-4. PLL Module Registers**

| Offset     | Acronym  | Register Description                              | Section                          |
|------------|----------|---------------------------------------------------|----------------------------------|

### 10.6.1 PLL Modulation Depth Measurement Control Register (SSWPLL1)

Figure 10-6 illustrates this register and Table 10-6 provides the bit descriptions. This register applies to PLL1, but does not apply to PLL2.

**Figure 10-6. SSW PLL BIST Control Register 1 (SSWPLL1) [offset = 24h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 10-6. SSW PLL BIST Control Register 1 (SSWPLL1) Field Descriptions**

| Bit   | Field                | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|----------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved             | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 15-8  | CAPTURE_WINDOW_INDEX | 0-FFh  | The capture counter present in the PLL wrapper will count the PLL clock edges when the current modulation phase capture window value is equal to these bits. Should be set equal to NR.                                                                                                                                                                                                                                                                                                                                                                 |
| 7     | Reserved             | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 6     | COUNTER_READ_READY   | 0<br>1 | Counter read ready.<br>Indicates that SSW_CAPTURE_COUNT (SSWPLL2) and SSW_CLKOUT_COUNT (SSWPLL3) can be read.<br>0 Counter registers in SSWPLL2 and SSWPLL3 are not ready to read.<br>1 Counter registers in SSWPLL2 and SSWPLL3 are ready to read.                                                                                                                                                                                                                                                                                                     |
| 5     | COUNTER_RESET        | 0<br>1 | Counter reset.<br>If EXT_COUNTER_EN = 0, COUNTER_RESET resets SSW_CAPTURE_COUNT (SSWPLL2) and SSW_CLKOUT_COUNT (SSWPLL3).<br>If EXT_COUNTER_EN = 1, this bit is ignored.<br>0 No impact to counters<br>1 If the EXT_COUNTER_EN bit is 0, then counters SSW_CAPTURE_COUNT and SSW_CLKOUT_COUNT will be held in the reset state.<br>If EXT_COUNTER_EN bit is 1, then this bit will be ignored by the PLL wrapper.                                                                                                                                         |
| 4     | COUNTER_EN           | 0<br>1 | Counter enable.<br>If EXT_COUNTER_EN = 0, COUNTER_EN initializes the modulation depth measurement. (In this mode, the disable is set to occur automatically.)<br>If EXT_COUNTER_EN = 1, the counters are enabled/disabled with COUNTER_EN.<br>0 If EXT_COUNTER_EN = 0, COUNTER_EN = 0 indicates that the counters are inactive.<br>If EXT_COUNTER_EN = 1, COUNTER_EN = 0 disables the counters.<br>1 If EXT_COUNTER_EN = 0, COUNTER_EN = 1 indicates that the counters are still active.<br>If EXT_COUNTER_EN = 1, COUNTER_EN = 1 enables the counters. |

**Table 10-6. SSW PLL BIST Control Register 1 (SSWPLL1) Field Descriptions (continued)**

| Bit | Field           | Value | Description                                                                                                                                                                                                                                                                                   |
|-----|-----------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3-1 | TAP_COUNTER_DIS |       | The value in this register is used to program a particular bit in CLKOUT counter. When that particular bit in CLKOUT counter becomes 1, then both the CLKOUT counter and the CAPTURE counter will stop counting when EXT_COUNTER_EN = 0. When EXT_COUNTER_EN = 1, this bit field is not used. |
|     |                 | 0     | Bit 16 of CLKOUT counter is selected. When this bit is set and the modulation period finishes, the counters are disabled and READ_READY_FLAG is set.                                                                                                                                          |
|     |                 | 1h    | Bit 18 of CLKOUT counter is selected.                                                                                                                                                                                                                                                         |
|     |                 | 2h    | Bit 20 of CLKOUT counter is selected.                                                                                                                                                                                                                                                         |
|     |                 | 3h    | Bit 22 of CLKOUT counter is selected.                                                                                                                                                                                                                                                         |
|     |                 | 4h    | Bit 24 of CLKOUT counter is selected.                                                                                                                                                                                                                                                         |
|     |                 | 5h    | Bit 26 of CLKOUT counter is selected.                                                                                                                                                                                                                                                         |
|     |                 | 6h    | Bit 28 of CLKOUT counter is selected.                                                                                                                                                                                                                                                         |
|     |                 | 7h    | Bit 30 of CLKOUT counter is selected.                                                                                                                                                                                                                                                         |
| 0   | EXT_COUNTER_EN  | 0     | Modulation Depth Measurement mode                                                                                                                                                                                                                                                             |
|     |                 | 1     | Frequency Measurement mode                                                                                                                                                                                                                                                                    |

### 10.6.2 SSW PLL BIST Control Register 2 (SSWPLL2)

This is an observation register used to log counter value for the capture counter inside the PLL wrapper. The SSWPLL2 register is shown in [Figure 10-7](#) and described in [Table 10-7](#). This register applies to PLL1, but does not apply to PLL2.

**Figure 10-7. SSW PLL BIST Control Register 2 (SSWPLL2) [offset = 28h]**

LEGEND: R = Read only; -n = value after reset

**Table 10-7. SSW PLL BIST Control Register 2 (SSWPLL2) Field Descriptions**

| Bit  | Field             | Value        | Description                                                                                                                                                                                                                         |
|------|-------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | SSW_CAPTURE_COUNT | 0-FFFF FFFFh | Capture count. This register returns the value of the capture count. When EXT_COUNTER_EN = 0, this counter increments within a fixed modulation window. When EXT_COUNTER_EN = 1, this counter increments based upon the oscillator. |

### 10.6.3 SSW PLL BIST Control Register 3 (SSWPLL3)

This is observation register used to log counter value for CLKOUT counter inside PLL wrapper. The SSWPLL3 register is shown in [Figure 10-8](#) and described in [Table 10-8](#). This register applies to PLL1, but does not apply to PLL2.

**Figure 10-8. SSW PLL BIST Control Register 3 (SSWPLL3) [offset = 2Ch]**

LEGEND: R = Read only; -n = value after reset

**Table 10-8. SSW PLL BIST Control Register 3 (SSWPLL3) Field Descriptions**

| Bit  | Field             | Value        | Description                                                                                                 |

## 10.7 Phase-Locked Loop Theory of Operation

The PLL block consists of six logical sub-blocks:

- Phase-Frequency Detector (PFD)
- Charge Pump (CP)
- Loop Filter (LF)
- Voltage-Controlled Oscillator (VCO)
- Frequency Modulation
- Slip Detector

Figure 10-9 illustrates the sub-blocks in a basic PLL circuit. The VCO adjusts its frequency until the two signals into the PFD have the same phase and frequency. The feedback path (from VCO to PFD) divides the frequency of the feedback signal by  $2 \times NF$ ; this feedback divider requires the VCO to generate a frequency  $2 \times NF$  times greater than the internal frequency ( $OSCIN/NR$ ). In the forward path (from VCO to PLL CLK), the  $/2$  block creates a clean duty cycle.

**Figure 10-9. Basic PLL Circuit**

### 10.7.1 Phase-Frequency Detector

The phase-frequency detector (PFD) compares the input reference phase/frequency to the phase/frequency of the feedback divider and generates two signals: an *up* pulse and a *down* pulse that drive a charge pump. The resulting charge, when integrated by the circuit at the LF pin, provides a VCO control voltage, as shown in Figure 10-10.

**Figure 10-10. PFD Timing**

The width of the up pulse and the down pulse depends on the difference in phase between the two inputs. For example, when the reference input leads the feedback input by 10 ns, then an up pulse of approximately 10 ns is generated (see Figure 10-10). On the other hand, when the reference input lags the feedback input by 10 ns, then a down pulse of approximately 10 ns is generated. When the two inputs are exactly in phase, the up pulse and down pulse become essentially zero-width. These pulses are fed to the charge pump block, which meters charge into the low-pass loop filter.

The advantage of a phase-frequency detector over a phase-only detector is that it cannot lock to a harmonic or subharmonic of the reference. This important property also ensures that the output frequency of the VCO is always exactly  $2 \times NF$  times the reference frequency.

The reference feedback frequency is based upon the VCO frequency and the feedback divider. Fractional multiplication is achieved by changing the feedback divider real-time in order to create the fractional multiplication. As an example, if a multiplier of 100.5 is selected, the feedback divider divides by 100 and 101 in equal proportions; in this case, the PLLMUL bit field would be programmed as 99.5 (0x6380). This fractional multiplication is useful when trying to achieve final frequencies that are non-integer to the input frequency (for example, a final frequency that is a prime number). The fractional portion of the divider should be small compared to the multiplier and so it is recommended that the fractional portion relate to parts in 16, implying that the last 4 bits should always be 0.

### 10.7.2 Charge Pump and Loop Filter

The charge pump (CP) add or remove charge from the loop filter based on the pulses coming from the phase-frequency detector (PFD).

Two components of the filter output signal are summed together: an integral component and a proportional component. The integral component maintains a DC level going to the VCO to set its frequency, and the proportional component makes the VCO track changes in phase to minimize jitter. The capacitors and resistors required for the filter are integrated in silicon.

### 10.7.3 Voltage-Controlled Oscillator

The output frequency of the VCO is proportional to its input control voltage, which is generated by the charge pump via the integrated loop filter. If the VCO oscillates too slowly, the feedback phase begins to lag the reference phase at the PFD, which increases the control voltage at the VCO. Conversely, if the VCO oscillates too fast, the feedback phase begins to lead the reference phase at the PFD, which decreases the control voltage at the VCO. These two actions keep the VCO running at the correct frequency multiple of the reference.

**Figure 10-11. PLL Modulation Block Diagram**

### 10.7.4 Frequency Modulation

The output clock of the PLL changes frequency in a controlled way, centered around the unmodulated output frequency. The modulation block directly modulates the VCO frequency at the loop filter, and creates the triangular frequency modulation (see [Figure 10-12](#)).

**Figure 10-12. Frequency vs. Time**

## 10.8 Programming Example

This section provides an example of how to program the PLL. For non-modulation settings, the PLLCTL1 and PLLCTL2 settings from 130nm process devices can be used without modification.

Suppose that, using a 20MHz crystal, the application requires:

- 180MHz GCLK (and HCLK) frequency
- 100 kHz spreading frequency
- 0.5% spreading depth

1. Choose an NR and NS such that:

$$\bullet \quad \frac{f_{CLKIN}}{NR \times f_s} \geq 40 \quad (15)$$

$$\bullet \quad f_s \equiv \frac{f_{CLKIN}}{2 \times NR \times NS} \quad (16)$$

$$\bullet \quad 2 \times NS = \frac{f_{CLKIN}}{NR \times f_s} \geq 40 \quad (17)$$

- (NR,NS) = {(5,20), (4,25), (2,50), (1,100)}
  - Either NR = 5 and NS = 20 or NR = 4 and NS = 25 are reasonable. Another choice (NR, NS) = (3, 33) is possible if the modulation frequency can vary from 100KHz.
2. Choose Output CLK frequency as integer divider of output frequency near to 330MHz. Output CLK frequency should not exceed 550MHz or fall below 110MHz.  
The integer values for 180MHz are 360MHz or 540MHz. 360MHz is close to the target frequency of 330MHz and we use this frequency.

3. In this case, either of the below equations are suitable choices for getting to 360MHz. Choose NR = 5, NS = 20 and set NF = 72.

$$\frac{f_{CLKIN}}{NR} = \frac{20[MHz]}{4} = 5[MHz] \text{ or } \frac{f_{CLKIN}}{NR} = \frac{20[MHz]}{5} = 4[MHz] \quad (18)$$

4. Select the output divider OD so that the post-ODCLK frequency does not exceed the maximum frequency of output divider R (device specific frequency). In this case, choose OD = 2 and R = 1.
5. Compute the divider value NV so that NV = 0.036.

$$Depth = \frac{0.5}{100} = \frac{NV}{NF} \times \frac{NS}{2} = \frac{NV}{72} \times \frac{20}{2} \quad (19)$$

6. If it is important to maintain the same average frequency in modulation as in non-modulation, either NF should be modified OR program the MULMOD bit field. The modulation fields create a multiplier offset equal to:

$$\Delta NF = \frac{NV \times NS}{2} \quad (20)$$

If using MULMOD[8:0], then:

$$\Delta NF = \frac{MULMOD[8...0]}{256} = \frac{NV \times NS}{2} = \frac{0.036 \times 20}{2} \quad (21)$$

$$MULMOD[8...0] = \frac{0.036 \times 20}{2} \times 256 = 92.16 \quad (22)$$

MULMOD will be set to 92.

7. Convert the PLL parameters into bit field values:
  - NR = 5 implies that REFCLKDIV[5:0] = 4
  - NS = 20 implies that SPRATE[8:0] = 19 = 0x13
  - NF = 72 implies that PLLMUL[15:0] = 0x4700
  - OD = 2 implies that ODPLL[2:0] = 1
  - R = 1 implies that PLLDIV[4:0] = 0
  - NV = 0.036 implies that SPRAMOUNT = 73 = 0x49
  - MULMOD = 92 = 0x5C
8. Setting only these fields (that is, not BPOS, ROF, or ROS) yields:

PLLCTL1 = 0x00044700

PLLCTL2 = 0x04C5C249

When FM ENA is turned on, PLLCTL2 = 0x84C5C249.

The Output CLK is centered in the range from 110MHz to 550MHz at 360MHz.

NF = 72 falls within the multiplier range from 1-256.

OD is selected so that post-ODCLK meets the device specification.

## ***Dual-Clock Comparator (DCC) Module***

---

---

This chapter describes the dual-clock comparator (DCC) module.

## 11.1 Introduction

The primary purpose of a DCC module is to measure the frequency of a clock signal using a second known clock signal as a reference. This capability can be used to ensure the correct frequency range for several different device clock sources, thereby enhancing the system safety metrics.

### 11.1.1 Main Features

The main features of each of the DCC modules are:

- Allows application to ensure that a fixed ratio is maintained between frequencies of two clock signals
- Supports the definition of a programmable tolerance window in terms of number of reference clock cycles
- Supports continuous monitoring without requiring application intervention
- Also supports a single-sequence mode for spot measurements
- Allows selection of clock source for each of the counters resulting in several specific use cases

### 11.1.2 Block Diagram

Figure 11-1 illustrates the main concept of the DCC module.

**Figure 11-1. DCC Operation**

## 11.2 Module Operation

As shown in [Figure 11-1](#), the DCC contains two counters – counter0 and counter1, which are driven by two signals – clock0 and clock1. The application programs the seed values for both these counters. The application also configures the tolerance window time by configuring the valid counter for clock0.

Counter0 and counter1 both start counting simultaneously once the DCC is enabled. When counter0 counts down to zero, this automatically triggers the count down of the tolerance window counter (valid0).

The DCC module can be used in two different operating modes:

### 11.2.1 Continuous Monitoring Mode

In this mode, the DCC is used by the application to ensure that two clock signals maintain the correct frequency ratio. Suppose the application wants to ensure that the PLL output signal (clock source # 1) always maintains a fixed frequency relationship with the main oscillator (clock source # 0).

- In this case, the application can use the main oscillator as the clock0 signal (for counter0 and valid0) and the PLL output as the clock1 (for counter1).
- The seed values of counter0, valid0 and counter1 are selected such that if the actual frequencies of clock0 and clock1 are equal to their expected frequencies, then the counter1 will reach zero either at the same time as counter0 or during the count down of the valid0 counter.
- If the counter1 reaches zero during the count down of the valid0 counter, then all the counters (counter0, valid0, counter1) are reloaded with their initial seed values once valid0 has also counted down to zero.
- This sequence of counting down and checking then continues as long as there is no error, or until the DCC module is disabled.
- The counters also all get reloaded if the application resets and restarts the DCC module.

#### Error Conditions:

An error condition is generated by any one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that clock1 is faster than expected, or clock0 is slower than expected. It includes the case when clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that clock1 is slower than expected. It includes the case when clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application may then read out the counter values to help determine what caused the error.

#### 11.2.1.1 Error Conditions

While operating in continuous mode, the counters get reloaded with the seed values and continue counting down under the following conditions:

- The module is reset or restarted by the application, OR
- Counter0, Valid 0 and Counter1 all reach 0 without any error

**Figure 11-2. Counter Relationship**

**Figure 11-3. Clock1 Slower Than Clock0 - Results in an Error and Stops Counting**

**Figure 11-4. Clock1 Faster Than Clock0 - Results in an Error and Stops Counting**

**Figure 11-5. Clock1 Not Present - Results in an Error and Stops Counting**

**Figure 11-6. Clock0 Not Present - Results in an Error and Stops Counting**

### 11.2.2 Single-Shot Measurement Mode

The DCC module can be programmed to count down one time by enabling the single-shot mode. In this mode, the DCC stops operating when the down counter0 and the valid counter0 reach 0. Alternatively, the DCC can be programmed to stop counting when the down counter1 reaches 0.

At the end of one sequence of counting down in this single-shot mode, the DCC gets disabled automatically, which prevents further counting. This mode is typically used for spot measurements of the frequency of a signal. This frequency could be an unknown for the application before the measurement.

#### Example Usage of Single-Shot Measurement Mode: Trimming the High-Frequency Low-Power Oscillator

A practical example of the usage of the spot measurement mode is in trimming the HF LPO (clock source # 5) using the main oscillator as a reference. This measurement sequence would proceed as follows:

- The application sets up the seed values for counter0 and valid0 for the duration of the measurement. Suppose the main oscillator frequency is 10MHz and the intended duration of the measurement is 500μs. The application needs to configure a seed value of 5000.
- These 5000 counts need to be divided between the counter0 and the valid0 counters. The minimum value for the valid0 seed is 4, so the application can configure counter0 seed value as 4996 and the valid0 seed value as 4.
- Suppose the HF LPO frequency is truly unknown. In this case the application can choose the maximum allowed seed value for counter1. This increases the probability of counter0 and valid0 counting down while the counter1 has still not fully counted down to zero. The maximum allowed seed value for counter1 is 1048575.
- Once the DCC is enabled, the counters counter0 and counter1 both start counting down from their seed values.
- When counter0 reaches zero, it automatically triggers the valid0 counter.
- When valid0 reaches zero, if counter1 is not zero as well, an ERROR status flag is set and a "DCC error" is sent to the ESM. Counter1 is also frozen so that it stops counting down any further. The application can enable an interrupt to be generated from the ESM whenever this DCC error is indicated. Refer the device datasheet to identify the ESM group and channel where the DCC error is connected.

- The DCC error interrupt service routine can then check the value of counter1 when the error was generated. Suppose that the counter1 now reads 1044575. This means that counter1 has counted 1048575 - 1044575, or 4000 cycles within the 500 $\mu$ s measurement period. This means that the average frequency of the HF LPO over this 500 $\mu$ s period was 4000 cycles / 500 $\mu$ s, or 8MHz.
- The application then needs to clear the ERROR status flag and restart the DCC module so that it is ready for the next spot measurement.

If there is no error generated at the end of the sequence, then the DONE status flag is set and a DONE interrupt is generated. The application must clear the DONE flag before restarting the DCC.

The conditions that cause a DCC error are identical between the continuous monitoring mode and the single-shot measurement mode.

#### Error Conditions:

An error condition is generated by any one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that clock1 is faster than expected, or clock0 is slower than expected. It includes the case when clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that clock1 is slower than expected. It includes the case when clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application may then read out the counter values to help determine what caused the error.

#### Freezing Counters when Counter1 Reaches Zero:

The DCC module also allows the counters to be frozen when the counter1 reaches zero. This allows one of the clock sources for counter1 to be used as a reference for measuring one of the clock sources for counter0. The error conditions are the same as those where (counter0=0 and valid0=0) define the condition when the DCC counters are frozen. That is, an error is indicated if counter0 and valid0 become zero while counter1 is still non-zero. In this case, however, the application would typically set up the seed values such that the counter1 will become zero before counter0. Essentially the measurement period is defined by the seed value of the counter1. Note that this is also an error condition, and the interrupt service routine can use the measurement period and the actual cycles counted by counter1 to determine the frequency of the clock0 signal.

### 11.3 Clock Source Selection for Counter0 and Counter1

Refer the device datasheet to identify the available options for selecting the clock sources for both counters of the DCC module. Some microcontrollers may include multiple instances of the DCC module. This will also be identified in the device datasheet.

The selection of the clock sources for counter0 and counter1 is done by a combination of the KEY, CNT0 CLKSRC and CNT1 CLKSRC control fields of the CNT0CLKSRC and CNT1CLKSRC registers.

## 11.4 DCC Control Registers

This section describes the dual-clock comparator (DCC) module control and status registers. The registers support 8-bit, 16-bit or 32-bit writes and are aligned on a word (32-bit) boundary. The table shows address offsets from the module base address. Please refer the device datasheet to identify the DCC modules' base addresses.

When an error occurs, the counters stop and this field is set to 5h automatically disabling the DCC counter in hardware.<br>Read: Counters are enabled.<br>Write: Load counters with their seed values and begin counting. It is recommended to write Ah to enable counters to protect against single-bit errors. |

### 11.4.2 DCC Revision Id Register (DCCREV)

Figure 11-8 and Table 11-3 describe the DCC Revision Id register.

**Figure 11-8. DCC Revision Id Register (DCCREV) [offset = 4h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 11-3. DCC Revision Id Register (DCCREV) Field Descriptions**

| Bit   | Field    | Value | Description                                                           |
|-------|----------|-------|-----------------------------------------------------------------------|
| 31-30 | SCHEME   | 01    | Reads return 01, writes have no effect.                               |
| 29-28 | Reserved | 0     | Read returns 0. Writes have no effect.                                |
| 27-16 | FUNC     | 0     | Functional release number. Reads return 0x000, writes have no effect. |
| 15-11 | RTL      | 0     | Design release number. Reads return 0x00, writes have no effect.      |
| 10-8  | MAJOR    | 2h    | Major revision number. Reads return 0x2, writes have no effect.       |
| 7-6   | CUSTOM   | 0     | Custom version number. Reads return 0x0, writes have no effect.       |
| 5-0   | MINOR    | 4h    | Minor revision number. Reads return 0x4, writes have no effect.       |

### 11.4.3 DCC Counter0 Seed Register (DCCCNT0SEED)

Figure 11-9 and Table 11-4 describe the DCC Counter0 Seed register.

**Figure 11-9. DCC Counter0 Seed Register (DCCCNT0SEED) [offset = 8h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 11-4. DCC Counter0 Seed Register (DCCCNT0SEED) Field Descriptions**

| Bit   | Field       | Value | Description                                                                                                                                                                    |
|-------|-------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-20 | Reserved    | 0     | Read returns 0. Writes have no effect.                                                                                                                                         |
| 19-0  | COUNT0 SEED |       | Seed value for DCC Counter0.<br>Read in any operating mode returns the current value of Counter0.<br>Writing in privileged mode only sets the current seed value for Counter0. |

**NOTE: Seed for Counter0 must be non-zero**

The DCC must only be enabled after programming a non-zero value in the COUNT0 SEED register.

#### 11.4.4 DCC Valid0 Seed Register (DCCVALID0SEED)

Figure 11-10 and Table 11-5 describe the DCC Valid0 Seed register.

**Figure 11-10. DCC Valid0 Seed Register (DCCVALID0SEED) [offset = Ch]**

|    |             |    |
|----|-------------|----|
| 31 | Reserved    | 16 |
|    | R-0         |    |
| 15 | VALID0 SEED | 0  |
|    | R/WP-0      |    |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 11-5. DCC Valid0 Seed Register (DCCVALID0SEED) Field Descriptions**

| Bit   | Field       | Value | Description                                                                                                                                                                                                                                                                                                                              |
|-------|-------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved    | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                   |
| 15-0  | VALID0 SEED |       | Seed value for DCC Valid0. This value defines the window within which the Counter1 must reach 0. This window needs to be at least 4 cycles wide.<br>Read in any operating mode returns the current value of seed for Valid0.<br>Writing in privileged mode only sets the current seed value for Valid0. Writes in user mode are ignored. |

**NOTE: Seed for Valid0 must be at least 0x4**

The DCC must only be enabled after programming a value greater than or equal to 0x4 in the VALID0 SEED register.

#### 11.4.5 DCC Counter1 Seed Register (DCCCNT1SEED)

Figure 11-11 and Table 11-6 describe the DCC Counter1 Seed register.

**Figure 11-11. DCC Counter1 Seed Register (DCCCNT1SEED) [offset = 10h]**

|    |             |    |             |    |

## ***Error Signaling Module (ESM)***

---

---

This chapter provides the details of the error signaling module (ESM) that aggregates device errors and provides internal and external error response based on error severity.

## 12.1 Overview

The Error Signaling Module (ESM) collects and reports the various error conditions on the microcontroller. The error condition is categorized based on a severity level. Error response is then generated based on the category of the error. Possible error responses include a low priority interrupt, high priority interrupt, and an external pin action.

### 12.1.1 Feature List

- Up to 128 error channels are supported, divided into 3 different groups:
  - 64 Group1 (low severity) channels with configurable interrupt generation and configurable  $\overline{\text{ERROR}}$  pin behavior
  - 32 Group2 (high severity) channels with predefined interrupt generation and predefined  $\overline{\text{ERROR}}$  pin behavior
  - 32 Group3 (high severity) channels with no interrupt generation and predefined  $\overline{\text{ERROR}}$  pin behavior. These channels have no interrupt response as they are reserved for CPU based diagnostics that generate aborts directly to the CPU.
- Dedicated device  $\overline{\text{ERROR}}$  pin to signal an external observer
- Configurable timebase for  $\overline{\text{ERROR}}$  pin output
- Error forcing capability for latent fault testing

### 12.1.2 Block Diagram

As shown in Figure 12-1, the ESM channels are divided into three groups. Group1 channels are considered to be low severity. Group1 errors have a configurable interrupt response and configurable  $\overline{\text{ERROR}}$  pin behavior. Note that the ESM Status Register 1 (ESMSR1) for error group 1 gets updated, regardless if the interrupt enable is active or not. Group2 channels are  $\overline{\text{ERROR}}$  high severity. Group2 errors always generate a high priority interrupt and an output on the  $\overline{\text{ERROR}}$  pin. Group3 errors are reserved for high severity errors generated by diagnostics which have already generated a CPU abort response. Because an abort response is generated, there is no need to generate an interrupt response. Group3 errors always generate an  $\overline{\text{ERROR}}$  pin output.

The ESM interrupt and  $\overline{\text{ERROR}}$  pin behavior are also summarized in Table 12-1.

**Figure 12-1. Block Diagram**

Note that the ESM Status Register 1 (ESMSR1) for error\_group1 gets updated, regardless if the interrupt enable is active or not.

**Table 12-1. ESM Interrupt and  $\overline{\text{ERROR}}$  Pin Behavior**

| Error Group | Interrupt Generated    | Interrupt priority    | $\overline{\text{ERROR}}$ pin response generated |
|-------------|------------------------|-----------------------|--------------------------------------------------|
| 1           | configurable interrupt | configurable priority | configurable output generation                   |
| 2           | interrupt generated    | high priority         | output generated                                 |
| 3           | no interrupt           | NA                    | output generated                                 |

Figure 12-2 and Figure 12-3 show the interrupt response handling and  $\overline{\text{ERROR}}$  pin response handling with register configuration. The total active time of the  $\overline{\text{ERROR}}$  pin is controlled by the Low-Time Counter Preload register (LTCP) and the key register (ESMEPSR) as shown in Figure 12-3. Please see Section 12.2.2 for details.

**Figure 12-2. Interrupt Response Handling**

**Figure 12-3.  $\overline{\text{ERROR}}$  Pin Response Handling**

## 12.2 Module Operation

This device has 128 error channels, divided into 3 different error groups. Please refer to the device datasheet for ESM channel assignment details.

The ESM module has error flags for each error channel. The error status registers ESMSR1, ESMSR4, ESMSR2, ESMSR3 provide status information on a pending error of Group1 (Channel 0-31), Group1 (Channel 32-63), Group2, and Group3, respectively. The ESMEPSR register provides the current  $\overline{\text{ERROR}}$  status. The module also provides a status shadow register, ESMSSR2, which maintains the error flags of Group2 until power-on reset ( $\overline{\text{PORRST}}$ ) is asserted. Please see [Section 12.2.1](#) for details of their behavior during power on reset and warm reset.

Once an error occurs, the ESM module will set the corresponding error flags. In addition, it can trigger an interrupt,  $\overline{\text{ERROR}}$  pin outputs low depending on the ESM settings. Once the  $\overline{\text{ERROR}}$  pin outputs low, a power on reset or a write of 0x5 to ESMEKR is required to release the ESM error pin back to normal state. Please see [Section 12.2.2](#) for details. The application can read the error status registers (ESMSR1, ESMSR4, ESMSR2, and ESMSR3) to debug the error. If an  $\overline{\text{RST}}$  is triggered or the error interrupt has been served, the error flag of Group2 should be read from ESMSSR2 because the error flag in ESMSR2 will be cleared by  $\overline{\text{RST}}$ .

The user can also test the functionality of the  $\overline{\text{ERROR}}$  pin by forcing an error. Please see [Section 12.2.3](#) for details.

### 12.2.1 Reset Behavior

Power on reset:

- $\overline{\text{ERROR}}$  pin behavior

When  $\overline{\text{PORRST}}$  is active, the  $\overline{\text{ERROR}}$  pin is in a high impedance state (output drivers disabled).

- Register behavior

After  $\overline{\text{PORRST}}$ , all registers in ESM module will be re-initialized to the default value. All the error status registers are cleared to zero.

Warm reset ( $\overline{\text{RST}}$ ):

- $\overline{\text{ERROR}}$  pin behavior

During  $\overline{\text{RST}}$ , the  $\overline{\text{ERROR}}$  pin is in “output active” state with pull-down disabled. The  $\overline{\text{ERROR}}$  pin remains unchanged after  $\overline{\text{RST}}$ .

- Register behavior

After  $\overline{\text{RST}}$ , ESMSR1, ESMSR4, ESMSSR2, ESMSR3 and ESMEPSR register values remains unchanged. Since  $\overline{\text{RST}}$  does not clear the critical failure registers, the user can read those registers to debug the failures after  $\overline{\text{RST}}$  pin goes back to high.

After  $\overline{\text{RST}}$ , if one of the flags in ESMSR1 and ESMSR4 is set, the interrupt service routine will be called once the corresponding interrupt is enabled.

---

**NOTE:** ESMSR2 is cleared after  $\overline{\text{RST}}$ . The flag in ESMSR2 gets cleared when reading the appropriate vector in the ESMIOFFHR offset register. Reading ESMIOFFHR will not clear the ESMSR1, ESMSR4, and the shadow register ESMSSR2. Reading ESMIOFFLR will also not clear the ESMSR1 and ESMSR4.

---

### 12.2.2 $\overline{\text{ERROR}}$ Pin Timing

The  $\overline{\text{ERROR}}$  pin is an active low function. The state of the pin is also readable from  $\overline{\text{ERROR}}$  Pin Status Register (ESMEPSR). A warm reset ( $\overline{\text{RST}}$ ) does not affect the state of the pin. The pin is in a high-impedance state during power-on reset. Once the ESM module drives the  $\overline{\text{ERROR}}$  pin low, it remains in this state for the time specified by the Low-Time Counter Preload register (LTCPR). Based on the time period of the peripheral clock (VCLK), the total active time of the  $\overline{\text{ERROR}}$  pin can be calculated as:

$$t_{\overline{\text{ERROR}}_{\text{low}}} = t_{\text{VCLK}} \times (\text{LTCP} + 1) \quad (23)$$

Once this period expires, the  $\overline{\text{ERROR}}$  pin is set to high in case the reset of the  $\overline{\text{ERROR}}$  pin was requested. This request is done by writing an appropriate key (0x5) to the key register (ESMEKR) during the  $\overline{\text{ERROR}}$  pin low time. Here are a few examples:

Example 1: ESM detects a failure and drives the  $\overline{\text{ERROR}}$  pin low. No  $\overline{\text{ERROR}}$  pin reset is requested. The  $\overline{\text{ERROR}}$  pin continues outputting low until power on reset occurs.

**Figure 12-4.  $\overline{\text{ERROR}}$  Pin Timing - Example 1**

Example 2: ESM detects a failure and drives the  $\overline{\text{ERROR}}$  pin low. An  $\overline{\text{ERROR}}$  pin reset request is received before  $t_{\text{ERROR\_low}}$  expires. In this case, the  $\overline{\text{ERROR}}$  pin is set to high immediately after  $t_{\text{ERROR\_low}}$  expires.

**Figure 12-5.  $\overline{\text{ERROR}}$  Pin Timing - Example 2**

Example 3: ESM detects a failure and drives the  $\overline{\text{ERROR}}$  pin low. An  $\overline{\text{ERROR}}$  pin reset request is received after  $t_{\text{ERROR\_low}}$  expires. In this case, the  $\overline{\text{ERROR}}$  pin is set to high immediately after  $\overline{\text{ERROR}}$  pin reset request is received.

**Figure 12-6.  $\overline{\text{ERROR}}$  Pin Timing - Example 3**

Example 4: ESM detects a failure and drives the  $\overline{\text{ERROR}}$  pin low. Another failure occurs within the time the pin stays low. In this case, the low time counter will be reset when the other failure occurs. In other words,  $t_{\text{ERROR\_low}}$  should be counted from whenever the most recent failure occurs.

**Figure 12-7.  $\overline{\text{ERROR}}$  Pin Timing - Example 4**

Example 5: The reset of the  $\overline{\text{ERROR}}$  pin was requested by the software even before the failure occurs. In this case, the  $\overline{\text{ERROR}}$  pin is set to high immediately after  $t_{\text{ERROR\_low}}$  expires. This case is not recommended and should be avoided by the application.

**Figure 12-8.  $\overline{\text{ERROR}}$  Pin Timing - Example 5**

### 12.2.3 Forcing an Error Condition

The error response generation mechanism is testable by software by forcing an error condition. This allows testing the  $\overline{\text{ERROR}}$  pin functionality. By writing a dedicated key to the error forcing key register (ESMEKR), the  $\overline{\text{ERROR}}$  pin is set to low for the specified time. The following steps describe how to force an error condition:

1. Check  $\overline{\text{ERROR}}$  Pin Status Register (ESMEPSR). This register must be “1” to switch into the error forcing mode.  
The ESM module cannot be switched into the error forcing mode if a failure has already been detected in functional mode. The application command to switch to error forcing mode is ignored.
2. Write “1010b” to the error forcing key register (ESMEKR). After that, the  $\overline{\text{ERROR}}$  pin should output low (error force mode).

Once the application puts the ESM module in the error forcing mode, the  $\overline{\text{ERROR}}$  pin cannot indicate the normal error functionality. If a failure occurs during this time, it gets still latched and the LTC is reset and stopped. The error output pin is already driven low on account of the error forcing mode. When the ESM is forced back to normal functional mode, the LTC becomes active and forces the  $\overline{\text{ERROR}}$  pin low until the expiration of the LTC (see Figure 12-9).

**Figure 12-9. ERROR Pin Timing - Example 6**

3. Write “0000” to the error forcing key register (ESMEKR) back to the active normal mode.  
If there are no errors detected while the ESM module is in the error forcing mode, the  $\overline{\text{ERROR}}$  pin goes high immediately after exiting the error forcing mode.

## 12.3 Recommended Programming Procedure

During the initialization stage, the application code should follow the recommendations in [Figure 12-10](#) to initialize the ESM.

**Figure 12-10. ESM Initialization**

Once an error occurs, it can trigger an interrupt,  $\overline{\text{ERROR}}$  pin outputs low depending on the ESM settings. Once the  $\overline{\text{ERROR}}$  pin outputs low, a power on reset or a write of 0x5 to ESMEKR is required to release the ESM back to normal state. The application can read the error status registers (ESMSR1, ESMSR4, ESMSR2, and ESMSR3) to debug the error. If an  $\overline{\text{RST}}$  is triggered or the error interrupt has been served, the error flag of Group2 should be read from ESMSSR2 because the error flag in ESMSR2 will be cleared by  $\overline{\text{RST}}$ .

## 12.4 Control Registers

This section describes the ESM registers. Each register begins on a 32-bit word boundary. The registers support 32-bit, 16-bit and 8-bit accesses. The base address for the control registers is FFFF F500h.

**Table 12-2. ESM Module Registers**

| Address    | Acronym    | Register Description                                    | Section                         |

### 12.4.15 ESM Error Key Register (ESMEKR)

**Figure 12-25. ESM Error Key Register (ESMEKR) [offset = FFFF F538h]**

LEGEND: R/W = Read/Write; R = Read; WP = Write in privileged mode only; -n = value after reset

**Table 12-17. ESM Error Key Register (ESMEKR) Field Descriptions**

| Bit  | Field    | Value            | Description                                                                                                                                     |
|------|----------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | Reserved | 0                | Read returns 0. Writes have no effect.                                                                                                          |
| 3-0  | EKEY     |                  | Error Key. The key to reset the <b>ERROR</b> pin or to force an error on the <b>ERROR</b> pin.                                                  |
|      |          |                  | <b>User and privileged mode (read):</b><br>Returns current value of the EKEY.                                                                   |
|      |          | 0                | <b>Privileged mode (write):</b><br>Activates normal mode (recommended default mode).                                                            |
|      |          | 5h               | The <b>ERROR</b> pin set to high when the low time counter (LTC) has completed; then the EKEY bit will switch back to normal mode (EKEY = 0000) |
|      |          | Ah               | Forces error on <b>ERROR</b> pin.                                                                                                               |
|      |          | All other values | Activates normal mode.                                                                                                                          |

### 12.4.16 ESM Status Shadow Register 2 (ESMSSR2)

This register is dedicated for Group2.

**Figure 12-26. ESM Status Shadow Register 2 (ESMSSR2) [offset = FFFF F53Ch]**

LEGEND: R/W = Read/Write; R = Read; C = Clear; WP = Write in privileged mode only; -n = value after reset/**PORRST**; X = Value unchanged

**Table 12-18. ESM Status Shadow Register 2 (ESMSSR2) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                                                                                              |
|------|-------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ESF   |       | Error Status Flag. Shadow register for status information on pending error.                                                                                                                              |
|      |       | 0     | <b>Read in User and Privileged mode. Write in Privileged mode only.</b><br>Read: No error occurred.<br>Write: Leaves the bit unchanged.                                                                  |
|      |       | 1     | Read: Error occurred.<br>Write: Clears the bit. ESMSSR2 is not impacted by this action.<br><b>Note:</b> Errors are stored until they are cleared by the software or at power-on reset ( <b>PORRST</b> ). |

### 12.4.17 ESM Influence $\overline{\text{ERROR}}$ Pin Set/Status Register 4 (ESMIEPSR4)

This register is dedicated for Group1.

|       |       | 1     | Read: Error occurred; interrupt is pending.<br>Write: Clears the bit.<br><b>Note:</b> After $\overline{\text{RST}}$ , if one of these flags are set and the corresponding interrupt are enabled, the interrupt service routine will be called. |

## ***Real-Time Interrupt (RTI) Module***

This chapter describes the functionality of the real-time interrupt (RTI) module. The RTI is designed as an operating system timer to support a real time operating system (RTOS).

---

**NOTE:** This chapter describes a superset implementation of the RTI module that includes features and functionality related to DMA, FlexRay, and Timbase control. These features are dependent on the device-specific feature content. Consult your device-specific datasheet to determine the applicability of these features to your device being used.

---

| Topic                               | Page       |
|-------------------------------------|------------|
| <b>13.1 Overview</b> .....          | <b>440</b> |
| <b>13.2 Module Operation</b> .....  | <b>441</b> |
| <b>13.3 Control Registers</b> ..... | <b>451</b> |

## 13.1 Overview

The real-time interrupt (RTI) module provides timer functionality for operating systems and for benchmarking code. The RTI module can incorporate several counters that define the timebases needed for scheduling in the operating system.

The timers also allow you to benchmark certain areas of code by reading the values of the counters at the beginning and the end of the desired code range and calculating the difference between the values.

In addition the RTI provides a mechanism to synchronize the operating system to the FlexRay communication cycle. Clock supervision allows for detection of issues on the FlexRay bus with an automatic switch to an internally generated timebase when a failure with the FlexRay timebase is detected.

### 13.1.1 Features

The RTI module has the following features:

- Two independent 64 bit counter blocks
- Four configurable compares for generating operating system ticks or DMA requests. Each event can be driven by either counter block 0 or counter block 1.
- One counter block usable for application synchronization to FlexRay network including clock supervision
- Fast enabling/disabling of events
- Two time stamp (capture) functions for system or peripheral interrupts, one for each counter block
- Digital windowed watchdog

### 13.1.2 Industry Standard Compliance Statement

This module is specifically designed to fulfill the requirements for OSEK (**O**ffene **S**ysteme und deren **S**chnittstellen für die **E**lektronik im **K**raftfahrzeug, or Open Systems and the Corresponding Interfaces for Automotive Electronics) as well as OSEK/time-compliant operating systems, but is not limited to it.

## 13.2 Module Operation

Figure 13-1 illustrates the high level block diagram of the RTI module.

The RTI module has two independent counter blocks for generating different timebases: counter block 0 and counter block 1. The two counter blocks provide the same basic functionality, but counter block 0 has the additional functionality of being able to work with the FlexRay Macrotick (NTU0) or Start of Cycle (NTU1) and perform clock supervision to detect a missing signal.

A compare unit compares the counters with programmable values and generates four independent interrupt or DMA requests on compare matches. Each of the compare registers can be programmed to be compared to either counter block 0 or counter block 1.

The following sections describe the individual functions in more detail.

**Figure 13-1. RTI Block Diagram**

### 13.2.1 Counter Operation

Each counter block consists of the following (see Figure 13-2):

- One 32-bit prescale counter (RTIUC0 or RTIUC1)
- One 32-bit free running counter (RTIFRC0 or RTIFRC1)

The RTIUC0/1 is driven by the RTICLK and counts up until the compare value in the compare up counter register (RTICPUC0 or RTICPUC1) is reached. When the compare matches, RTIFRC0/1 is incremented and RTIUC0/1 is reset to 0. If RTIFRC0/1 overflows, an interrupt is generated to the vectored interrupt manager (VIM). The overflow interrupt is not intended to generate the timebase for the operating system. See Section 13.2.2 for the timebase generation. The up counter together with the compare up counter value prescale the RTI clock. The resulting formula for the frequency of the free running counter (RTIFRC0/1) is:

$$f_{\text{RTIFRCx}} = \begin{cases} \frac{f_{\text{RTICLK}}}{\text{RTICPUCx} + 1} & \text{when RTICPUCx} \neq 0 \\ \frac{f_{\text{RTICLK}}}{2^{32} + 1} & \text{when RTICPUCx} = 0 \end{cases} \quad (24)$$

**NOTE:** Setting RTICPUCx equal to zero is not recommended. Doing so will hold the Up Counter at zero for two RTICLK cycles after it overflows from 0xFFFFFFFF to zero.

The counter values can be determined by reading the respective counter registers or by generating a hardware event which captures the counter value into the respective capture register. Both functions are described in the following sections.

**Figure 13-2. Counter Block Diagram**

### 13.2.1.1 Counter and Capture Read Consistency

Portions of the device internal databus is 32-bits wide. If the application wants to read the 64-bit counters or the 64-bit capture values, a certain order of 32-bit read operations needs to be followed. This is to prevent one counter incrementing in between the two separate read operations to both counters.

#### Reading the Counters

The free running counter (RTIFRCx) must be read first. This priority will ensure that in the cycle when the CPU reads RTIFRCx, the up counter value is stored in its counter register (RTIUCx). The second read has to access the up counter register (RTIUCx), which then holds the value which corresponds to the number of RTICLK cycles that have elapsed at the time reading the free running counter register (RTIFRCx).

---

**NOTE:** The up counters are implemented as shadow registers. Reading RTIUCx without having read RTIFRCx first will return always the same value. RTIUCx will only be updated when RTIFRCx is read.

---

#### Reading the Capture Values

The free running counter capture register (RTICAFRCx) must be read first. This priority will ensure that in the cycle when the CPU reads RTICAFRCx, the up counter value is stored in its counter register (RTICAUCx). The second read has to access the up counter register (RTICAUCx), which then holds the value captured at the time when reading the capture free running counter register (RTICAFRCx).

---

**NOTE:** The capture up counter registers are implemented as shadow registers. Reading RTICAUCx without having read RTICAFRCx first will return always the same value. RTICAUCx will only be updated when RTICAFRCx is read.

---

### 13.2.1.2 Capture Feature

Both counter blocks also provide a capture feature on external events. Two capture sources can trigger the capture event. The source triggering the block is configurable (RTICAPCTRL). The sources originate from the Vectored Interrupt Manager (VIM) and allow the generation of capture events when a peripheral modules has generated an interrupt. Any of the peripheral interrupts can be selected as the capture event in the VIM.

When an event is detected, RTIUCx and RTIFRCx are stored in the capture up counter (RTICAUCx) and capture free running counter (RTICAFRCx) registers. The read order of the captured values must be the same as the read order of the actual counters (see [Section 13.2.1.1](#)).

### 13.2.2 Interrupt/DMA Requests

There are four compare registers (RTICOMP<sub>y</sub>) to generate interrupt requests to the VIM or DMA requests to the DMA controller. The interrupts can be used to generate different timebases for the operating system. Each of the compare registers can be configured to be compared to either RTIFRC0 or RTIFRC1. When the counter value matches the compare value, an interrupt is generated. To allow periodic interrupts, a certain value can be added to the compare value in RTICOMP<sub>y</sub> automatically. This value is stored in the update compare register (RTIUDCP<sub>y</sub>) and will be added after a compare is matched. The period of the generated interrupt/DMA request can be calculated with:

$$t_{COMPx} = t_{RTICLK} \times (RTICPUCy + 1) \times RTIUDCPy$$

if RTICPUC<sub>y</sub> = 0,

$$t_{COMPx} = t_{RTICLK} \times (2^{32} + 1) \times RTIUDCPy$$

if RTIUDCP<sub>y</sub> = 0,

$$t_{COMPx} = t_{RTICLK} \times (RTICPUCy + 1) \times 2^{32} \quad (25)$$

**Figure 13-3. Compare Unit Block Diagram (shows only 1 of 4 blocks for simplification)**

Another interrupt that can be generated is the overflow interrupt (OVLINTx) in case the RTIFRCx counter overflows.

The interrupts/DMA requests can be enabled in the RTISETINTENA register and disabled in the RTICLEARINTENA register. The RTIINTFLAG register shows the pending interrupts.

### 13.2.3 RTI Clocking

The counter blocks are clocked with RTICLK (for definition see [Section 2.4.2, Clock Domains](#)). Counter block 0 can be clocked in addition by either the FlexRay Macrotick (NTU0) or the FlexRay Start of Cycle (NTU1).

A clock supervision for the NTUx clocking scheme is implemented to avoid missing operating system ticks.

### 13.2.4 Synchronizing Timer Events to Network Time (NTU)

For applications which are participating on a time-triggered communication bus, it is often beneficial to synchronize the application or operating system to the network time. The RTI provides a feature to increment Free Running Counter 0 (RTIFRC0) by a periodic clock provided by the communication module. In this case two different clocks can be chosen. One is the FlexRay module Macrotick (NTU0) and the other is the Start of Cycle (NTU1) information of the same module.

The application has control over which clock (RTICLK, NTU0, NTU1) should be used for clocking RTIFRC0. If NTUx is used, a clock supervision circuit allows to monitor this clock and provides a fallback solution, should the clock be non-functional (missing). A too fast running NTUx cannot be detected.

RTIUC0 is utilized to monitor the NTUx signal. A detection window can be programmed in which a valid NTU clock pulse needs to occur. If no pulse is detected, the RTI automatically switches back to clock the Free Running Counter 0 with RTIUC0. In order to avoid a big jitter in the operating ticks, in case a switch back to RTIUC0 happens, RTICPUC0 should be set to a value so the clock frequency RTIUC0 outputs is approximately the same as the NTUx frequency.

Figure 13-4. Timebase Control

#### 13.2.4.1 Detecting Clock Edges

To detect clock edges on the NTUx signal, the timebase low compare has to be set lower or equal than the value stored in the RTICPUC0 register and the timebase high compare has to be set higher than 0 and lower than the timebase low compare value. This effectively opens a window in which an edge of the NTUx signal is expected (see Figure 13-5). Outside this window, no edges will be detected. If no edge will occur inside the detection window, the multiplexer is switched to internal timebase. The application can select to generate a timebase interrupt (TBINT) and if the INC bit is set, also will automatically increment RTIFRC0 by one to compensate for the missed clock cycle of NTUx. If an edge occurs inside the window, RTIUC0 will be reset to synchronize the two timebases.

In order to make the edge detection work properly, the value in RTICPUC0 needs to be adapted so that RTIUC0 has a similar period as NTUx.

**NOTE:** To ensure the NTUx signal is properly detected, the NTUx period must be at least twice as long as the RTICLK period.

Figure 13-5. Clock Detection Scheme

### 13.2.4.2 Switching from Internal Source to External Source

If the application switches from an internal source to an external source, the two signals must be synchronized (see Figure 13-6). The synchronization will occur when the TBEXT bit is set. RTIUC0 will be reset and the edge detection circuit will be active for one (RTICPUC0 + RTITBHCOMP) period or until an edge is detected. If there is no pulse during this period, the source will be reset from an external clock source to an internal clock source. If an edge is detected, the windowed edge detection behavior will take place. Setting the TBEXT bit will not increment free running counter 0.

**NOTE:** If an external timebase is used, then the software must ensure that timebase low compare and timebase high compare are programmed to a valid state before switching TBEXT to an external source. This state is necessary to allow the timebase control circuit to operate correctly. The following condition must be met:

- $RTITBHCOMP < RTITBLCOMP \leq RTICPUC0$

RTITBHCOMP must be lower than RTICPUC0 because RTIUC0 will be reset if RTICPUC0 is reached. RTITBHCOMP will represent the number of RTICLK cycles from RTICPUC0 until the circuit switches to the internal timebase when no NTU edge is detected.

If an external timebase is used, RTIGCTRL[0] must be set to 1 (enable RTIUC0) to ensure that the timebase control circuit does not wait indefinitely for an incoming signal.

Figure 13-6 shows a timing example for the synchronization phase when the TBEXT bit is set.

### 13.2.4.3 Switching from External Source to Internal Source

When the edge detection is active (TBEXT = 1) and no clock edge of NTUx is detected inside the programmed detection window, the RTI will automatically switch the timebase to RTIUC0. Figure 13-7 shows a timing example for a missing NTU signal. In the case where the INC bit is set, RTIFRC0 will automatically be incremented by one to compensate for the missed NTU pulse.

Setting TBEXT = 0 will also switch the clock source for RTIFRC0 to RTIUC0.

Figure 13-7. Missing NTUx Signal Example

### 13.2.5 Digital Watchdog (DWD)

The digital watchdog (DWD) is an optional safety diagnostic which can detect a runaway CPU and generate either a reset or NMI (non-maskable interrupt) response. It generates resets or NMIs after a programmable period, or if no correct key sequence was written to the RTIWDKEY register. Figure 13-8 illustrates the DWD.

Figure 13-8. Digital Watchdog

### 13.2.5.1 Digital Watchdog (DWD)

The DWD is disabled by default. If it should be used, it must be enabled by writing a 32-bit value, which is the inverted value of the hardwired code in the module, to the RTIDWDCTRL register.

**NOTE:** Once the DWD is enabled, it cannot be disabled except by system reset or power on reset.

If the correct key sequence is written to the RTIWDKEY register (0xE51A followed by 0xA35C), the 25-bit DWD down counter is reloaded with the left justified 12-bit preload value stored in RTIDWDPRLD. If an incorrect value is written, a watchdog reset or NMI will occur immediately. A reset or NMI will also be generated when the DWD down counter is decremented to 0.

While the device is in suspend mode (halting debug mode), the DWD down counter keeps the value it had when entering suspend mode.

The DWD down counter will be decremented with the RTICLK frequency.

**Figure 13-9. DWD Operation**

The expiration time of the DWD down counter can be determined with the following equation:

$$t_{exp} = (DWDPRLD + 1) \times 2^{13} / RTICLK$$

where

$$DWDPRLD = 0 \dots 4095$$

**NOTE:** Care should be taken to ensure that the CPU write to the watchdog register is made allowing time for the write to propagate to the RTI.

### 13.2.5.2 Digital Windowed Watchdog (DWWD)

In addition to the time-out boundary configurable via the digital watchdog discussed in [Section 13.2.5.1](#), for enhanced safety metrics it is desirable to check for a watchdog "pet" within a time window rather than using a single time threshold. This is enabled by the digital windowed watchdog (DWWD) feature.

- Functional Behavior

The DWWD opens a configurable time window in which the watchdog must be serviced. Any attempt to service the watchdog outside this time window, or a failure to service the watchdog in this time window, will cause the watchdog to generate either a reset or a NMI to the CPU. This is controlled by configuring the RTIWWDRXNCTRL register. As with the DWD, the DWWD is disabled after power on reset. When the DWWD is configured to generate a non-maskable interrupt on a window violation, the watchdog counter continues to count down. The NMI handler needs to clear the watchdog violation status flag(s) and then

service the watchdog by writing the correct sequence in the watchdog key register. This service will cause the watchdog counter to get reloaded from the preload value and start counting down. If the NMI handler does not service the watchdog in time, it could count down all the way to zero and wrap around. If the NMI Handler does not service the watchdog in time, the NMI gets generated continuously, each time the counter counts to '0'.

The DWWD uses the Digital Watchdog (DWD) preload register (RTIDWDPRLD) setting to define the end-time of the window. The start-time of the window is defined by a window size configuration register(RTIWWD SIZECTRL).

The default window size is set to 100%, which corresponds to the DWD functionality of a time-out-only watchdog. The window size can be selected (through register RTIWWD SIZECTRL) from among 100%, 50%, 25%, 12.5%, 6.25% and 3.125% as shown in Figure 13-10. The window with the respective size will be opened before the end of the DWD expiration. The user has to serve the watchdog in the window. Otherwise, a reset or NMI will generate. Figure 13-11 shows an DWWD operation example (25% window).

- Configuration of DWWD

The DWWD preload value (same as DWD preload) can only be configured when the DWWD counter is disabled. The window size and watchdog reaction to a violation can be configured even after the watchdog has been enabled. Any changes to the window size and watchdog reaction configurations will only take effect after the next servicing of the DWWD. This feature can be utilized to dynamically set windows of different sizes based on task execution time, adding a program sequence element to the diagnostic which can improve fault coverage.

Figure 13-10. Digital Windowed Watchdog Timing Example

Figure 13-11. Digital Windowed Watchdog Operation Example (25% Window)

### 13.2.6 Low Power Modes

Low power modes allow the trade off of the current used during low power versus functionality and fast wakeup response. All low power modes have the following characteristics:

- CPU and system clocks are disabled.
- Flash banks and pump are in sleep mode.
- All peripheral modules are in low power modes and the clocks are disabled (exceptions to this may occur and would be documented in the specific device data sheet).

Flexibility in enabling and disabling clocks allows for many different low-power modes (see [Section 2.4.3, Low Power Modes](#)).

The operation of the RTI Module is guaranteed in Run, Doze and Snooze modes. In Sleep mode, all clocks will be switched off and the RTI will not work.

In Doze and Snooze modes, the RTI is active and is able to wake up the device with compare, timebase and overflow interrupts. The compare interrupts can be used to periodically wake up the device. The overflow interrupt can be used to notify the operating system that a counter overflow has occurred. Capturing events generated by the Vectored Interrupt Module (VIM) is also possible since, in both of these low power modes, the peripheral modules are able to generate interrupts that can trigger capture events. Capturing events while in Sleep mode is not supported as the clock to the RTI is not active.

When the device is put into low power mode, the peripheral which is generating the external clock NTU is no longer active, and the timebase control circuitry has to switch to an internal clocking scheme when it detects a missing clock on NTU. The timebase interrupt will wake up the device and the application software has to adapt the periodic interrupt generation to the internal clock source.

DMA transfers will be disabled, and DMA requests will not be generated after device wakeup since the DMA controller will be powered down.

---

**NOTE: RTICK in Doze Mode**

In the special case of Doze Mode with PLL off, RTICK might have a different period than with PLL enabled since RTICK will be derived from the oscillator output. It has to be ensured that the VCLK to RTICK ratio is at least 3:1.

---

### 13.2.7 Halting Debug Mode Behaviour

Once the system enters halting debug mode, the behavior of the RTI depends on the COS (continue on suspend) bit. If the bit is cleared and halting debug mode is active, all counters will stop operation. If the bit is set to one, all counters will be clocked normally and the RTI will work like in normal mode. However, if the external timebase (NTU) is used and the system is in halting debug mode, the timebase control circuit will switch to internal timebase once it detects the missing NTU signal of the suspended communication controller. This will be signaled with an TBINT interrupt so that software can resynchronize after the device exits halting debug mode.

### 13.3 Control Registers

[Table 13-1](#) provides a summary of the registers. The registers support 8-bit, 16-bit, and 32-bit writes. The offset is relative to the associated peripheral select. See the following sections for detailed descriptions of the registers. The base address for the control registers is FFFF FC00h. The address locations not listed are reserved.

**Table 13-1. RTI Registers**

| Offset | Acronym        | Register Description                                   | Section                         |

### 13.3.1 RTI Global Control Register (RTIGCTRL)

The global control register starts/stops the counters and selects the signal compared with the timebase control circuit. This register is shown in [Figure 13-12](#) and described in [Table 13-2](#).

**Figure 13-12. RTI Global Control Register (RTIGCTRL) [offset = 00]**

|          |          |     |    |        |        |

| Bit   | Field    | Value                                    | Description                                                                                                                                                                                                                                                |
|-------|----------|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-20 | Reserved | 0                                        | Reads return 0. Writes have no effect.                                                                                                                                                                                                                     |
| 19-16 | NTUSEL   | 0h<br>5h<br>Ah<br>Fh<br>All other values | Select NTU signal. These bits determine which NTU input signal is used as external timebase<br>NTU0<br>NTU1<br>NTU2<br>NTU3<br>Tied to 0                                                                                                                   |
| 15    | COS      | 0<br>1                                   | Continue on suspend. This bit determines if both counters are stopped when the device goes into halting debug mode or if they continue counting.<br>Counters are stopped while in halting debug mode.<br>Counters are running while in halting debug mode. |
| 14-2  | Reserved | 0                                        | Reads return 0. Writes have no effect.                                                                                                                                                                                                                     |
| 1     | CNT1EN   | 0<br>1                                   | Counter 1 enable. This bit starts and stops counter block 1 (RTIUC1 and RTIFRC1).<br>Counter block 1 is stopped.<br>Counter block 1 is running.                                                                                                            |
| 0     | CNT0EN   | 0<br>1                                   | Counter 0 enable. This bit starts and stops counter block 0 (RTIUC0 and RTIFRC0).<br>Counter block 0 is stopped.<br>Counter block 0 is running.                                                                                                            |

**NOTE:** If the application uses the timebase circuit for synchronization between the communications controller and the operating system and the device enters halting debug mode, the synchronization may be lost depending on the COS setting in the RTI module and the halting debug mode behavior of the communications controller.

### 13.3.2 RTI Timebase Control Register (RTITBCTRL)

The timebase control register selects if the free running counter 0 is incremented by RTICLK or NTU. This register is shown in [Figure 13-13](#) and described in [Table 13-3](#).

**Figure 13-13. RTI Timebase Control Register (RTITBCTRL) [offset = 04h]**

| Bit  | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|----------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0      | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 1    | INC      | 0<br>1 | Increment free running counter 0. This bit determines whether the free running counter 0 (RTIFRC0) is automatically incremented if a failing clock on the NTU signal is detected.<br>RTIFRC0 will not be incremented on a failing external clock.<br>RTIFRC0 will be incremented on a failing external clock.                                                                                                                                                                           |
| 0    | TBEXT    | 0<br>1 | Timebase external. This bit selects whether the free running counter 0 (RTIFRC0) is clocked by the internal up counter 0 (RTIUC0) or from the external signal NTU. Setting the TBEXT bit from 0 to 1 will not increment RTIFRC0, since RTIUC0 is reset.<br>When the timebase supervisor circuit detects a missing clock edge, then the TBEXT bit is reset.<br>Only the software can select whether the external signal should be used.<br>RTIUC0 clocks RTIFRC0.<br>NTU clocks RTIFRC0. |

### 13.3.3 RTI Capture Control Register (RTICAPCTRL)

The capture control register controls the capture source for the counters. This register is shown in [Figure 13-14](#) and described in [Table 13-4](#).

**Figure 13-14. RTI Capture Control Register (RTICAPCTRL) [offset = 08h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 13-4. RTI Capture Control Register (RTICAPCTRL) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                            |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reads return 0. Writes have no effect.                                                                                 |
| 1    | CAPCNTR1 | 0     | Capture counter 1. This bit determines which external interrupt source triggers a capture event of RTIUC1 and RTIFRC1. |
|      |          | 0     | Capture of RTIUC1/ RTIFRC1 is triggered by capture event source 0.                                                     |
|      |          | 1     | Capture of RTIUC1/ RTIFRC1 is triggered by capture event source 1.                                                     |
| 0    | CAPCNTR0 | 0     | Capture counter 0. This bit determines which external interrupt source triggers a capture event of RTIUC0 and RTIFRC0. |
|      |          | 0     | Capture of RTIUC0/ RTIFRC0 is triggered by capture event source 0.                                                     |
|      |          | 1     | Capture of RTIUC0/ RTIFRC0 is triggered by capture event source 1.                                                     |

### 13.3.4 RTI Compare Control Register (RTICOMPCTRL)

The compare control register controls the source for the compare registers. This register is shown in [Figure 13-15](#) and described in [Table 13-5](#).

**Figure 13-15. RTI Compare Control Register (RTICOMPCTRL) [offset = 0Ch]**

|     |          |  |  |          |    |    |     |          |  |  |          |   |   |        |  |  |    |

**Table 13-7. RTI Up Counter 0 Register (RTIUC0) Field Descriptions**

| Bit  | Field | Value        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------|-------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | UC0   | 0-FFFF FFFFh | Up counter 0. This register holds the current value of the up counter 0 and prescales the RTI clock. It will be only updated by a previous read of free running counter 0 (RTIFRC0). This method of updating effectively gives a 64-bit read of both counters, without having the problem of a counter being updated between two consecutive reads on up counter 0 (RTIUC0) and free running counter 0 (RTIFRC0).<br><br>A read of this counter returns the value of the counter at the time RTIFRC0 was read.<br><br>A write to this counter presets it with a value. The counter then increments from this written value upwards.<br><br>Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC0 and RTIFRC0.<br><br><b>Note: If the preset value is bigger than the compare value stored in register RTICPUC0, then it can take a long time until a compare matches, since RTIUC0 has to count up until it overflows.</b> |

### 13.3.7 RTI Compare Up Counter 0 Register (RTICPUC0)

The compare up counter 0 register holds the value to be compared with prescale counter 0 (RTIUC0). This register is shown in [Figure 13-18](#) and described in [Table 13-8](#).

**Figure 13-18. RTI Compare Up Counter 0 Register (RTICPUC0) [offset = 18h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 13-8. RTI Compare Up Counter 0 Register (RTICPUC0) Field Descriptions**

| Bit  | Field | Value        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------|-------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CPUC0 | 0-FFFF FFFFh | <p>Compare up counter 0. This register holds the value that is compared with the up counter 0. When the compare shows a match, the free running counter 0 (RTIFRC0) is incremented. RTIUC0 is set to 0 when the counter value matches the RTICPUC0 value. The value set in this register prescales the RTI clock.</p> <p>If CPUC0 = 0, then<br/> <math>f_{FRC0} = RTICLK / (2^{32} + 1)</math> (Not recommended. See note on <a href="#">Equation 24</a>)</p> <p>If CPUC0 ≠ 0, then<br/> <math>f_{FRC0} = RTICLK / (RTICPUC0 + 1)</math></p> <p>A read of this register returns the current compare value.</p> <p>A write to this register:</p> <ul style="list-style-type: none"> <li>• If TBEXT = 0, the compare value is updated.</li> <li>• If TBEXT = 1, the compare value is unchanged.</li> </ul> |

### 13.3.8 RTI Capture Free Running Counter 0 Register (RTICAFRC0)

The capture free running counter 0 register holds the free running counter 0 on external events. This register is shown in [Figure 13-19](#) and described in [Table 13-9](#).

**Figure 13-19. RTI Capture Free Running Counter 0 Register (RTICAFRC0) [offset = 20h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

| Bit  | Field | Value        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------|-------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CAUC0 | 0-FFFF FFFFh | <p>Capture up counter 0. This register captures the current value of the up counter 0 (RTIUC0) when an event occurs, controlled by the external capture control block.</p> <p><b>Note:</b> The read sequence must be the same as with RTIUC0 and RTIFRC0. Therefore, the RTICAFRC0 register must be read before the RTICAUC0 register is read. This sequence ensures that the value of the RTICAUC0 register is the corresponding value to the RTICAFRC0 register, even if another capture event happens in between the two reads.</p> <p>A read of this register returns the value of RTIUC0 on a capture event.</p> |

### 13.3.10 RTI Free Running Counter 1 Register (RTIFRC1)

The free running counter 1 register holds the current value of the free running counter 1. This register is shown in [Figure 13-21](#) and described in [Table 13-11](#).

**Figure 13-21. RTI Free Running Counter 1 Register (RTIFRC1) [offset = 30h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 13-13. RTI Compare Up Counter 1 Register (RTICPUC1) Field Descriptions**

| Bit  | Field | Value        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------|-------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CPUC1 | 0-FFFF FFFFh | <p>Compare up counter 1. This register holds the compare value, which is compared with the up counter 1. When the compare matches, the free running counter 1 (RTIFRC1) is incremented. The up counter is cleared to zero when the counter value matches the CPUC1 value. The value set in this prescales the RTI clock according to the following formula:</p> <p>If CPUC1 = 0, then<br/> <math>f_{FRC0} = RTICLK / (2^{32} + 1)</math> (Not recommended. See note on <a href="#">Equation 24</a>)</p> <p>If CPUC1 <math>\neq</math> 0, then<br/> <math>f_{FRC1} = RTICLK / (RTICPUC1 + 1)</math></p> <p>A read of this register returns the current compare value.<br/> A write to this register updates the compare value.</p> |

### 13.3.13 RTI Capture Free Running Counter 1 Register (RTICAFRC1)

The capture free running counter 1 register holds the current value of free running counter 1 on external events. This register is shown in [Figure 13-24](#) and described in [Table 13-14](#).

**Figure 13-24. RTI Capture Free Running Counter 1 Register (RTICAFRC1) [offset = 40h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 13-14. RTI Capture Free Running Counter 1 Register (RTICAFRC1) Field Descriptions**

| Bit  | Field  | Value        | Description                                                                                                                                                                                                                                                       |
|------|--------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CAFRC1 | 0-FFFF FFFFh | Capture free running counter 1. This register captures the current value of the free running counter 1 (RTIFRC1) when an event occurs, controlled by the external capture control block. A read of this register returns the value of RTIFRC1 on a capture event. |

### 13.3.14 RTI Capture Up Counter 1 Register (RTICAUC1)

The capture up counter 1 register holds the current value of prescale counter 1 on external events. This register is shown in [Figure 13-25](#) and described in [Table 13-15](#).

**Figure 13-25. RTI Capture Up Counter 1 Register (RTICAUC1) [offset = 44h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

| Bit  | Field | Value        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|-------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CAUC1 | 0-FFFF FFFFh | Capture up counter 1. This register captures the current value of the up counter 1 (RTIUC1) when an event occurs, controlled by the external capture control block.<br><br><b>Note: The RTICAFRC1 register must be read before the RTICAUC1 register is read. This sequence ensures that the value of the RTICAUC1 register is the corresponding value to the RTICAFRC1 register, even if another capture event happens in between the two reads.</b><br><br>A read of this register returns the value of RTIUC1 on a capture event. |

### 13.3.15 RTI Compare 0 Register (RTICOMP0)

The compare 0 register holds the value to be compared with the counters. This register is shown in [Figure 13-26](#) and described in [Table 13-16](#).

**Figure 13-26. RTI Compare 0 Register (RTICOMP0) [offset = 50h]**

| 31-0 | UDCP3 | 0-FFFF FFFFh | Update compare 3. This register holds a value that is added to the value in the RTICOMP3 register each time a compare matches. This process makes it possible to generate periodic interrupts without software intervention.<br><br>A read of this register will return the value to be added to the RTICOMP3 register on the next compare match.<br>A write to this register will provide a new update value. |

### 13.3.23 RTI Timebase Low Compare Register (RTITBLCOMP)

The timebase low compare register holds the value to activate the edge detection circuit. This register is shown in [Figure 13-34](#) and described in [Table 13-24](#).

**Figure 13-34. RTI Timebase Low Compare Register (RTITBLCOMP) [offset = 70h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 13-24. RTI Timebase Low Compare Register (RTITBLCOMP) Field Descriptions**

| Bit  | Field   | Value        | Description                                                                                                                                                                                                                                                                                                                                                                             |
|------|---------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | TBLCOMP | 0-FFFF FFFFh | Timebase low compare value. This value determines when the edge detection circuit starts monitoring the NTU signal. It will be compared with RTIUC0.<br><br>A read of this register will return the current compare value.<br><br>A write to this register has the following effects:<br>If TBEXT = 0: The compare value is updated.<br>If TBEXT = 1: The compare value is not changed. |

### 13.3.24 RTI Timebase High Compare Register (RTITBHCOMP)

The timebase high compare register holds the value to deactivate the edge detection circuit. This register is shown in [Figure 13-35](#) and described in [Table 13-25](#).

**Figure 13-35. RTI Timebase High Compare Register (RTITBHCOMP) [offset = 74h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 13-25. RTI Timebase High Compare Register (RTITBHCOMP) Field Descriptions**

| Bit  | Field   | Value        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------|---------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | TBHCOMP | 0-FFFF FFFFh | Timebase high compare value. This value determines when the edge detection circuit will stop monitoring the NTU signal. It will be compared with RTIUC0.<br><br>RTITBHCOMP must be less than RTICPUC0 because RTIUC0 will be reset when RTICPUC0 is reached.<br><br>Example: The NTU edge detection circuit should be active $\pm 10$ RTICLK cycles around RTICPUC0.<br><ul style="list-style-type: none"> <li>RTICPUC0 = 0050h</li> <li>RTITBLCOMP = 0046h</li> <li>RTITBHCOMP = 0009h</li> </ul> A read of this register will return the current compare value.<br><br>A write to this register has the following effects:<br>If TBEXT = 0: The compare value is updated.<br>If TBEXT = 1: The compare value is not changed. |

### 13.3.25 RTI Set Interrupt Enable Register (RTISETINTENA)

This register prevents the necessity of a read-modify-write operation if a particular interrupt should be enabled. This register is shown in [Figure 13-36](#) and described in [Table 13-26](#).

**Figure 13-36. RTI Set Interrupt Control Register (RTISETINTENA) [offset = 80h]**

### 13.3.27 RTI Interrupt Flag Register (RTIINTFLAG)

The corresponding flags are set at every compare match of the RTIFRCx and RTICOMPx values, whether the interrupt is enabled or not. This register is shown in [Figure 13-38](#) and described in [Table 13-28](#).

**Figure 13-38. RTI Interrupt Flag Register (RTIINTFLAG) [offset = 88h]**

| 0   | INT0  | 0     | Interrupt flag 0. These bits determine if an interrupt due to a Compare 0 match is pending.<br><i>Read:</i> No interrupt is pending.<br><i>Write:</i> Bit is unchanged. |
|     |       | 1     | <i>Read:</i> Interrupt is pending.<br><i>Write:</i> Bit is cleared to 0.                                                                                                |

### 13.3.28 Digital Watchdog Control Register (RTIDWDCTRL)

The software has to write to the DWDCTRL field in order to enable the DWD, as described below. Once enabled, the watchdog can only be disabled by a system reset. The application cannot disable the watchdog. However should the RTICLK source be changed to a source that is unimplemented it will have the same effect as disabling the watchdog. This register is shown in [Figure 13-38](#) and described in [Table 13-28](#).

**Figure 13-39. Digital Watchdog Control Register (RTIDWDCTRL) [offset = 90h]**

The DWD preload register can be configured only when the DWD is disabled. Therefore, the application can only configure the DWD preload register before it enables the DWD down counter.<br><br>The expiration time of the DWD Down Counter can be determined with following equation:<br>$texp = (DWDPRLD + 1) \times 2^{13} / RTICLK1$ where: DWDPRLD = 0...4095 |

### 13.3.30 Watchdog Status Register (RTIWDSTATUS)

This register records the status of the DWD. The values of the following status bits will not be affected by a soft reset. These bits are cleared by a power up reset, or by a write of '1'. These bits can be used for debug purposes. This register is shown in [Figure 13-38](#) and described in [Table 13-28](#).

### 13.3.31 RTI Watchdog Key Register (RTIWDKEY)

This register must be written with the correct written key values to serve the watchdog. This register is shown in [Figure 13-42](#) and described in [Table 13-32](#).

**NOTE:** It has to be taken into account that the write to the RTIWDKEY register takes 3 VCLK cycles.

**Figure 13-42. RTI Watchdog Key Register (RTIDWDKEY) [offset = 9Ch]**

### 13.3.33 Digital Windowed Watchdog Reaction Control (RTIWWDRXNCTRL)

This register selects the DWWD reaction if the watchdog is serviced outside the time window. This register is shown in [Figure 13-44](#) and described in [Table 13-35](#).

**Figure 13-44. Digital Windowed Watchdog Reaction Control (RTIWWDRXNCTRL) [offset = A4h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 13-35. Digital Windowed Watchdog Reaction Control (RTIWWDRXNCTRL) Field Descriptions**

| Bit  | Field    | Value            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|      |          | 5h               | The windowed watchdog will cause a reset if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|      |          | Ah               | The windowed watchdog will generate a non-maskable interrupt to the CPU if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all.                                                                                                                                                                                                                                                                                                                                                                                                                |
|      |          | All other values | The windowed watchdog will cause a reset if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all.<br><br><b>Note:</b> The DWWD reaction can be selected by the application even when the DWWD counter is already enabled. If a change to the WWDRXN is made before the watchdog service window is opened, then the change in the configuration takes effect immediately. If a change to the WWDRXN is made when the watchdog service window is already open, then the change in configuration takes effect only after the watchdog is serviced. |

### 13.3.34 Digital Windowed Watchdog Window Size Control (RTIWWDSIZECTRL)

This register selects the DWWD window size. This register is shown in [Figure 13-45](#) and described in [Table 13-36](#).

|      |         |                  | <b>Note:</b> The DWWD window size can be selected by the application even when the DWWD counter is already enabled. If a change to the WWDSIZE is made before the watchdog service window is opened, then the change in the configuration takes effect immediately. If a change to the WWDSIZE is made when the watchdog service window is already open, then the change in configuration takes effect only after the watchdog is serviced. |

### 13.3.35 RTI Compare Interrupt Clear Enable Register (RTIINTCLREnable)

This register enables an "auto-clear" of the compare interrupt enable bit after a compare equal event. This register is shown in [Figure 13-46](#) and described in [Table 13-37](#).

**Figure 13-46. RTI Compare Interrupt Clear Enable Register (RTIINTCLREnable) [offset = ACh]**

### 13.3.36 RTI Compare 0 Clear Register (RTICMP0CLR)

This registers holds a compare value, which is compared with the counter selected in the RTICOMPCTRL register [Section 13.3.4](#). If the Free Running Counter matches the compare value, the compare 0 interrupt or DMA request line is cleared and the value in the RTIUDCP0 register [Section 13.3.16](#) is added to this register. This register is shown in [Figure 13-47](#) and described in [Table 13-38](#).

## ***Cyclic Redundancy Check (CRC) Controller Module***

This chapter describes the cyclic redundancy check (CRC) controller module.

---

**NOTE:** This chapter describes a superset implementation of the CRC module that includes features and functionality that require DMA. Since not all devices have DMA capability, consult your device-specific datasheet to determine applicability of these features and functions to your device being used.

## 14.1 Overview

The CRC controller is a module that is used to perform CRC (Cyclic Redundancy Check) to verify the integrity of memory system. A signature representing the contents of the memory is obtained when the contents of the memory are read into CRC controller. The responsibility of CRC controller is to calculate the signature for a set of data and then compare the calculated signature value against a pre-determined good signature value. CRC controller supports two channels to perform CRC calculation on multiple memories in parallel and can be used on any memory system.

### 14.1.1 Features

The CRC controller offers:

- Two channels to perform background signature verification on any memory sub-system.
- Data compression on 8, 16, 32, and 64 bit data size.
- Maximum-length PSA (Parallel Signature Analysis) register constructed based on 64 bit primitive polynomial.
- Each channel has a CRC Value Register which contains the pre-determined CRC value.
- Use timed base event trigger from timer to initiate DMA data transfer.
- Programmable 20-bit pattern counter per channel to count the number of data patterns for compression.
- Three modes of operation. Auto, Semi-CPU and Full-CPU.
- For each channel, CRC can be performed either by CRC Controller or by CPU.
- Automatically perform signature verification without CPU intervention in AUTO mode.
- Generate interrupt to CPU in Semi-CPU mode to allow CPU to perform signature verification itself.
- Generate CRC fail interrupt in AUTO mode if signature verification fails.
- Generate Timeout interrupt if CRC is not performed within the time limit.
- Generate DMA request per channel to initiate CRC value transfer.
- Data trace capability on Peripheral Bus Master, Flash and System RAM data buses.

### 14.1.2 Block Diagram

[Figure 14-1](#) shows a block diagram of the CRC controller.

---

**NOTE:** Only Channel 1 can support data trace.

---

**Figure 14-1. CRC Controller Block Diagram For One Channel**

## 14.2 Module Operation

### 14.2.1 General Operation

There are two channels in CRC controller and for each channel there is a memory mapped PSA (Parallel Signature Analysis) Signature Register and a memory mapped CRC (Cyclic Redundancy Check) Value register. A memory can be organized into multiple sectors with each sector consisting of multiple data patterns. A data pattern can be a 8, 16, 32, or 64 bit data. CRC module performs the signature calculation and compares the signature to a pre-determined value. The PSA Signature Register compresses an incoming data pattern into a signature when it is written. When one sector of data patterns are written into PSA Signature Register, a final signature corresponding to the sector is obtained. CRC Value Register stores the pre-determined signature corresponding to one sector of data patterns. The calculated signature and the pre-determined signature are then compared to each other for signature verification. To minimize CPU's involvement, data patterns transfer can be carried out at the background of CPU using DMA controller. DMA is setup to transfer data from memory from which the contents to be verified to the memory mapped PSA Signature Register. When DMA transfers data to the memory mapped PSA Signature Register, a signature is generated. A programmable 20-bit data pattern counter is used for each channel to define the number of data patterns to calculate for each sector. Signature verification can be performed automatically by CRC controller in AUTO mode or by CPU itself in Semi-CPU or Full-CPU mode. In AUTO mode, a self sustained CRC signature calculation can be achieved without any CPU intervention. CRC Controller also provides data trace capability. Channel 1 can perform data trace on CPU data bus. During data trace, channel 1 monitors any data being read on CPU data bus and compresses it. When data trace is enabled for channel 1, all circuits related to DMA request and interrupt generation and counters are disabled.

### 14.2.2 CRC Modes of Operation

CRC Controller can operate in AUTO, Semi-CPU, and Full-CPU modes.

#### 14.2.2.1 AUTO Mode

In AUTO mode, CRC Controller in conjunction with DMA controller can perform CRC totally without CPU intervention. A sustained transfer of data to both the PSA Signature Register and CRC Value Register are performed in the background of CPU. When a mismatch is detected, an interrupt is generated to CPU. A 16 bit current sector ID register is provided to identify which sector causes a CRC failure.

#### 14.2.2.2 Semi-CPU Mode

In Semi-CPU mode, DMA controller is also utilized to perform data patterns transfer to PSA Signature Register. Instead of performing signature verification automatically, the CRC controller generates an compression complete interrupt to CPU after each sector is compressed. Upon responding to the interrupt the CPU performs the signature verification by reading the calculated signature stored at the PSA Sector Signature Register and compare it to a pre-determined CRC value.

#### 14.2.2.3 Full CPU Mode

In Full-CPU mode, the CPU does the data patterns transfer and signature verification all by itself. When CPU has enough throughput, it can perform data patterns transfer by reading data from the memory system to the PSA Signature Register. After certain number of data patterns are compressed, the CPU can read from the PSA Signature Register and compare the calculated signature to the pre-determined CRC signature value. In Full-CPU mode, neither interrupt nor DMA request is generated. All counters are also disabled.

### 14.2.3 PSA Signature Register

The 64-bit PSA Signature Register is based on the primitive polynomial (as in the following equation) to produce the maximum length LFSR (Linear Feedback Shift Register), as shown in Figure 14-2.

$$f(x) = x^{64} + x^4 + x^3 + x + 1 \quad (26)$$

Figure 14-2. LFSR

The serial implementation of LFSF has a limitation that, it requires 'n' clock cycles to calculate the CRC values for an 'n' bit data stream. The idea is to produce the same CRC value operating on a multi-bit data stream, as would occur if the CRC were computed one bit at a time over the whole data stream. The algorithm involves looping to simulate the shifting, and concatenating strings to build the equations after 'n' shift.

The parallel CRC calculation based on the polynomial can be illustrated in the following HDL code:

```
for i in 63 to 0 loop
  NEXT_CRC_VAL(0) := CRC_VAL(63) xor DATA(i);
  for j in 1 to 63 loop
    case j is
      when 1|3|4 =>
        NEXT_CRC_VAL(j) :=
          CRC_VAL(j - 1) xor CRC_VAL(63) xor DATA(i);
      when others =>
        NEXT_CRC_VAL(j) := CRC_VAL(j - 1);
    end case;
  end loop;
  CRC_VAL := NEXT_CRC_VAL;
end loop;
```

- NOTE:**
- 1) The inner loop is to calculate the next value of each shift register bit after one cycle
  - 2) The outer loop is to simulate 64 cycles of shifting. The equation for each shift register bit is thus built before it is compressed into the shift register.
  - 3) MSB of the DATA is shifted in first

There is one PSA Signature Register per CRC channel. PSA Signature Register can be both read and written. When it is written, it can either compress the data or just capture the data depending on the state of CHx\_MODE bits. If CHx\_MODE=Data Capture, a seed value can be planted in the PSA Signature Register without compression. Other modes other than Data Capture will result with the data compressed by PSA Signature Register when it is written. Each channel can be planted with different seed value before compression starts. When PSA Signature Register is read, it gives the calculated signature.

CRC Controller should be used in conjunction with the on chip DMA controller to produce optimal system performance. The incoming data pattern to PSA Signature Register is typically initiated by the DMA master. When DMA is properly setup, it would read data from the pre-determined memory system and write them to the memory mapped PSA Signature Register. Each time PSA Signature Register is written a signature is generated. CPU itself can also perform data transfer by reading from the memory system and perform write operation to PSA Signature Register if CPU has enough throughput to handle data patterns transfer.

After system reset and when AUTO mode is enabled, CRC Controller automatically generates a DMA request to request the pre-determined CRC value corresponding to the first sector of memory to be checked.

In AUTO mode, when one sector of data patterns is compressed, the signature stored at the PSA Signature Register is first copied to the PSA Sector Signature Register and PSA Signature Register is then cleared out to all zeros. An automatic signature verification is then performed by comparing the signature stored at the PSA Sector Signature Register to the CRC Value Register. After the comparison the CRC Controller can generate a DMA request. Upon receiving the DMA request the DMA controller will update the CRC Value Register by transferring the next pre-determined signature value associated with the next sector of memory system. If the signature verification fails then CRC Controller can generate a CRC fail interrupt.

In Full-CPU mode, no DMA request and interrupt are generated at all. The number of data patterns to be compressed is determined by CPU itself. Full-CPU mode is useful when DMA controller is not available to perform background data patterns transfer. The OS can periodically generate a software interrupt to CPU and use CPU to accomplish data transfer and signature verification.

CRC Controller supports doubleword, word, half word and byte access to the PSA Signature Register. During a non-doubleword write access, all unwritten byte lanes are padded with zero's before compression. Note that comparison between PSA Sector Signature Register and CRC Value Register is always in 64 bit because a compressed value is always expressed in 64 bit.

There is a software reset per channel for PSA Signature Register. When set, the PSA Signature Register is reset to all zeros.

PSA Signature Register is reset to zero under the following conditions:

- System reset
- PSA Software reset
- One sector of data patterns are compressed

#### **14.2.4 PSA Sector Signature Register**

After one sector of data is compressed, the final resulting signature calculated by PSA Signature Register is transferred to the PSA Sector Signature Register. PSA Signature Register is a read only register. During Semi-CPU mode, the host CPU should read from the PSA Sector Signature Register instead of reading from PSA Signature Register for signature verification to avoid data coherency issue. The PSA Signature Register can be updated with new signature before the host CPU is able to retrieve it.

In Semi-CPU mode, no DMA request is generated. When one sector of data patterns is compressed, CRC controller first generates a compression complete interrupt. Responding to the interrupt, CPU will in the ISR read the PSA Sector Signature Register and compare it to the known good signature or write the signature value to another memory location to build a signature file. In Semi-CPU mode, CPU must perform the signature verification in a manner to prevent any overrun condition. The overrun condition occurs when the compression complete interrupt is generated after one sector of data patterns is compressed and CPU has not read from the PSA Sector Signature Register to perform necessary signature verification before PSA Sector Signature Register is overridden with a new value. An overrun interrupt can be enable to generate when overrun condition occurs. During Semi-CPU mode, the host CPU should read from the PSA Sector Signature Register instead of reading from PSA Signature Register for signature verification to avoid data coherency issue. The PSA Signature Register can be updated with new signature before the host CPU is able to retrieve it.

### 14.2.5 CRC Value Register

Associated with each channel there is a CRC Value Register. The CRC Value Register stores the pre-determined CRC value. After one sector of data patterns is compressed by PSA Signature Register, CRC Controller can automatically compare the resulting signature stored at the PSA Sector Signature Register with the pre-determined value stored at the CRC Value Register if AUTO mode is enabled. If the signature verification fails, CRC Controller can be enabled to generate an CRC fail interrupt. When the channel is set up for Semi-CPU mode, CRC controller first generates a compression complete interrupt to CPU. Upon servicing the interrupt, CPU will then read the PSA Sector Signature Register and then read the corresponding CRC value stored at another location and compare them. CPU should not read from the CRC Value Register during Semi-CPU or Full-CPU mode because the CRC Value Register is not updated during these two modes.

In AUTO mode, for first sector's signature, DMA request is generated when mode is programmed to AUTO. For subsequent sectors, DMA request is generated after each sector is compressed. Responding to the DMA request, DMA controller reloads the CRC Value Register for the next sector of memory system to be checked.

When CRC Value Register is updated with a new CRC value, an internal flag is set to indicate that CRC Value Register contains the most current value. This flag is cleared when CRC comparison is performed. Each time at the end of the final data pattern compression of a sector, CRC Controller first checks to see if the corresponding CRC Value Register has the most current CRC value stored in it by polling the flag. If the flag is set then the CRC comparison can be performed. If the flag is not set then it means the CRC Value Register contains stale information. A CRC underrun interrupt is generated. When an underrun condition is detected, signature verification is not performed.

CRC Controller supports doubleword, word, half word and byte access to the CRC Value Register. As noted before comparison between PSA Sector Signature Register and CRC Value Register during AUTO mode is carried out in 64 bit.

### 14.2.6 Raw Data Register

The raw or un-compressed data written to the PSA Signature Register is also saved in the Raw Data Register. This register is read only.

### 14.2.7 Example DMA Controller Setup

DMA controller needs to be setup properly in either either AUTO or Semi-CPU mode as DMA controller is used to transfer data patterns. Hardware or a combination of hardware and software DMA triggering are supported.

#### 14.2.7.1 AUTO Mode Using Hardware Timer Trigger

There are two DMA channels associated with each CRC channel when in AUTO mode. One DMA channel is setup to transfer data patterns from the source memory to the PSA Signature Register. The second DMA channel is setup to transfer the pre-determined signature to the CRC Value Register. The trigger source for the first DMA channel can be either by hardware or by software. As illustrated in [Figure 14-3](#) a timer can be used to trigger a DMA request to initiate transfer from the source memory system to PSA Signature Register. In AUTO mode, CRC Controller also generates DMA request after one sector of data patterns is compressed to initiate transfer of the next CRC value corresponding to the next sector of memory. Thus a new CRC value is always updated in the CRC Value Register by DMA synchronized to each sector of memory.

A block of memory system is usually divided into many sectors. All sectors are the same size. The sector size is programmed in the CRC\_PCOUNT\_REGx and the number of sectors in one block is programmed in the CRC\_SCOUNT\_REGx of the respective channel. CRC\_PCOUNT\_REGx multiplies CRC\_SCOUNT\_REGx and multiplies transfer size of each data pattern should give the total block size in number of bytes.

The total size of the memory system to be examined is also programmed in the respective transfer count register inside DMA module. The DMA transfer count register is divided into two parts. They are element count and frame count. Note that an HW DMA request can be programmed to trigger either one frame or one entire block transfer. In [Figure 14-3](#), an HW DMA request from a timer is used as a trigger source to initiate DMA transfer. If all four CRC channels are active in AUTO mode then a total of four DMA requests would be generated by CRC Controller.

**Figure 14-3. AUTO Mode Using Hardware Timer Trigger**

#### 14.2.7.2 AUTO Mode Using Software Trigger

The data patterns transfer can also be initiated by software. CPU can generate a software DMA request to activate the DMA channel to transfer data patterns from source memory system to the PSA Signature Register. To generate a software DMA request CPU needs to set the corresponding DMA channel in the DMA software trigger register. Note that just one software DMA request from CPU is enough to complete the entire data patterns transfer for all sectors. See [Figure 14-4](#) for an illustration.

**Figure 14-4. AUTO Mode With Software CPU Trigger**

### 14.2.7.3 Semi-CPU Mode Using Hardware Timer Trigger

During semi-CPU mode, no DMA request is generated by CRC controller. Therefore, no DMA channel is allocated to update CRC Value Register. CPU should not read from CRC Value Register in semi-CPU mode as it contains stale value. Note that no signature verification is performed at all during this mode. Similar to AUTO mode, either by hardware or by software DMA request can be used as a trigger for data patterns transfer. Figure 14-5 illustrates the DMA setup using semi-CPU mode with hardware timer trigger.

**Figure 14-5. Semi-CPU Mode With Hardware Timer Trigger**

**Table 14-1. CRC Modes in Which DMA Request and Counter Logic are Active or Inactive**

| Mode     | DMA Request | Pattern Counter | Sector Counter | Timeout Counter |
|----------|-------------|-----------------|----------------|-----------------|
| AUTO     | Active      | Active          | Active         | Active          |
| Semi-CPU | Inactive    | Active          | Active         | Active          |
| Full-CPU | Inactive    | Inactive        | Inactive       | Inactive        |

### 14.2.8 Pattern Count Register

There is a 20-bit data pattern counter for every CRC channel. The data pattern counter is a down counter and can be pre-loaded with a programmable value stored in the Pattern Count Register. When the data pattern counter reaches zero, a compression complete interrupt is generated in Semi-CPU mode and an automatic signature verification is performed in AUTO mode. In AUTO only, DMA request is generated to trigger the DMA controller to update the CRC Value Register.

**NOTE:** The data pattern count should be divisible by the total transfer count as programmed in DMA controller. The total transfer count is the product of element count and frame count.

### 14.2.9 Sector Count Register/Current Sector Register

Each channel contains a 16 bit sector counter. The sector count register stores the number of sectors. Sector counter is a free running counter and is incremented by one each time when one sector of data patterns is compressed. When the signature verification fails, the current value stored in the sector counter is saved into current sector register. If signature verification fails, CPU can read from the current sector register to identify the sector which causes the CRC mismatch. To aid and facilitate the CPU in determining the cause of a CRC failure, it is advisable to use the following equation during CRC and DMA setup:

$$\text{CRC Pattern Count} \times \text{CRC Sector Count} = \text{DMA Element Count} \times \text{DMA Frame Count}$$

The current sector register is frozen from being updated until both the current sector register is read and CRC fail status bit is cleared by CPU. If CPU does not respond to the CRC failure in a timely manner before another sector produces a signature verification failure, the current sector register is not updated with the new sector number. An overrun interrupt is generate instead. If current sector register is already frozen with an erroneous sector and emulation is entered with SUSPEND signal goes to high then the register still remains frozen even it is read.

In Semi-CPU mode, the current sector register is used to indicate the sector for which the compression complete has last happened.

The current sector register is reset when the PSA software reset is enabled.

---

**NOTE:** Both data pattern count and sector count registers must be greater than or equal to one for the counters to count. After reset, pattern count and sector count registers default to zero and the associated counters are inactive.

---

### 14.2.10 Interrupt

The CRC controller generates several types of interrupts per channel. Associated with each interrupt, there is an interrupt enable bit. No interrupt is generated in Full-CPU mode.

- Compression complete interrupt
- CRC fail interrupt
- Overrun interrupt
- Underrun interrupt
- Timeout interrupt

**Table 14-2. Modes in Which Interrupt Condition Can Occur**

|                      | AUTO | Semi-CPU | Full-CPU |
|----------------------|------|----------|----------|
| Compression Complete | no   | yes      | no       |
| CRC Fail             | yes  | no       | no       |
| Overrun              | yes  | yes      | no       |
| Underrun             | yes  | no       | no       |
| Timeout              | yes  | yes      | no       |

#### 14.2.10.1 Compression Complete Interrupt

Compression complete interrupt is generated in Semi-CPU mode only. When the data pattern counter reaches zero, the compression complete flag is set and the interrupt is generated.

#### 14.2.10.2 CRC Fail Interrupt

CRC fail interrupt is generated in AUTO mode only. When the signature verification fails, the CRC fail flag is set,. CPU should take action to address the fail condition and clear the CRC fail flag after it resolves the CRC mismatch.

#### 14.2.10.3 Overrun Interrupt

Overrun interrupt is generate in either either AUTO or Semi-CPU mode. During AUTO mode, if a CRC fail is detected then the current sector number is recorded in the current sector register. If CRC fail status bit is not cleared and current sector register is not read by the host CPU before another CRC fail is detected for another sector then an overrun interrupt is generated. During Semi-CPU mode, when the data pattern counter finishes counting, it generates a compression complete interrupt. At the same time the signature is copied into the PSA Sector Signature Register. If the host CPU does not read the signature from PSA Sector Signature Register before it is updated again with a new signature value then an overrun interrupt is generated.

#### 14.2.10.4 Underrun Interrupt

Underrun interrupt only occurs in AUTO mode. The interrupt is generated when the CRC Value Register is not updated with the corresponding signature when the data pattern counter finishes counting. During AUTO mode, CRC Controller generates DMA request to update CRC Value Register in synchronization to the corresponding sector of the memory. Signature verification is also performed if underrun condition is detected. And CRC fail interrupt is generated at the same time as the underrun interrupt.

#### 14.2.10.5 Timeout Interrupt

To ensure that the memory system is examined within a pre-defined time frame and no loss of incoming data there is a 24 bit timeout counter per CRC channel. The 24 bit timeout down counter can be pre-loaded with two different pre-load values, watchdog timeout pre-load value (CRC\_WDTPLDx) and block complete timeout pre-load value (CRC\_BCTOPLDx). The timeout counter is clocked by a prescaler clock which is permanently running at division 64 of HCLK clock.

First pattern of data must be transferred by the DMA before the timeout counter expires, Watchdog timeout pre-load register (CRC\_WDTPLDx) is used as timeout counter. Block complete timeout pre-load register (CRC\_BCTOPLDx) is used to check if one complete block of data patterns are compressed within a specific time frame. The timeout counter is first pre-loaded with CRC\_WDTPLDx after either AUTO or Semi-CPU mode is selected and starts to down count. If the timeout counter expires before DMA transfers any data pattern to PSA Signature Register then a timeout interrupt is generated. An incoming data pattern before the timeout counter expires will automatically pre-load the timeout counter with CRC\_BCTOPLDx the block complete timeout pre-load value.

Block complete timeout pre-load value is used to check if one block of data patterns are compressed within a given time limit. If the timeout counter pre-loaded with CRC\_BCTOPLDx value expires before one block of data patterns are compressed a timeout interrupt is generated. When one block (pattern count x sector count) of data patterns are compressed before the counter has expired, the counter is pre-loaded with CRC\_WDTPLDx value again. If the timeout counter is pre-loaded with zero then the counter is disable and no timeout interrupt is generated.

In Figure 14-6, a timer generates DMA request every 10ms to trigger one block (pattern count x sector count) transfer. Since we want to make sure that DMA does start to transfer a block every 10 ms we would set the first pre-load value to 10ms in CRC\_WDTPLDx. We also want to make sure that one block of data patterns are compressed within 4ms. With such a requirement, we would set the second pre-load value to 4ms in CRC\_BCTOPLDx register.

Figure 14-6. Timeout Example 1

**Figure 14-7. Timeout Example 2**

WD pre-load = watchdog timeout pre-load (CRC\_WDTPLDx)

BC pre-load = block complete timeout pre-load (CRC\_BCTPLDx)

Note: Timeout interrupt is generated in this example since each block of data patterns are compressed in 6 ms and this is out of the 4ms time frame.

**Figure 14-8. Timeout Example 3**

WD pre-load = watchdog timeout pre-load (CRC\_WDTPLDx)

BC pre-load = block complete timeout pre-load (CRC\_BCTPLDx)

Note: Timeout interrupt is generated in this example since DMA can not transfer the second block of data within 10ms time limit and the reason may be that DMA is set up in fixed priority scheme and DMA is serving other higher priority channels at the time before it can service the timer request.

### 14.2.10.6 Interrupt Offset Register

CRC Controller only generates one interrupt request to interrupt manager. A interrupt offset register is provided to indicate the source of the pending interrupt with highest priority. [Table 14-3](#) shows the offset interrupt vector address of each interrupt condition in an ascending order of priority.

**Table 14-3. Interrupt Offset Mapping**

| Offset Value | Interrupt Condition      |
|--------------|--------------------------|
| 0            | Phantom                  |
| 1h           | Ch1 CRC Fail             |
| 2h           | Ch2 CRC Fail             |
| 3h-8h        | Reserved                 |
| 9h           | Ch1 Compression Complete |
| Ah           | Ch2 Compression Complete |
| Bh-10h       | Reserved                 |
| 11h          | Ch1 Overrun              |
| 12h          | Ch2 Overrun              |
| 13h-18h      | Reserved                 |
| 19h          | Ch1 Underrun             |
| 1Ah          | Ch2 Underrun             |
| 1Bh-20h      | Reserved                 |
| 21h          | Ch1 Timeout              |
| 22h          | Ch2 Timeout              |
| 23h-24h      | Reserved                 |

### 14.2.10.7 Error Handling

When an interrupt is generated, host CPU should take appropriate actions to identify the source of error and restart the respective channel in DMA and CRC module. To restart a CRC channel, the user should perform the following steps in the ISR:

1. Write to software reset bit in *CRC\_CTRL* register to reset the respective PSA Signature Register.
2. Reset the CHx\_MODE bits to "00" in *CRC\_CTRL* register as Data capture mode.
3. Set the CHx\_MODE bits in *CRC\_CTRL* register to desired new mode again.
4. Release software reset.

The host CPU should use byte write to restart each individual channel.

### 14.2.11 CPU Data Trace

CRC channel 1 can be used to snoop Flash, System RAM and Peripheral Bus Master Data buses. However, at any one point only one bus is snooped. It is possible to disable the snooping of any of the buses by programming *CRC\_BUS\_SEL* register. While snooping the data, there is a priority scheme implemented between the buses. Peripheral Bus Master has the highest priority followed by FLash, Even System RAM and Odd System RAM. For each data read by CPU on its data bus the same data is compressed in the PSA Signature Register. A write to PSA Signature Register does not get compressed. Therefore, it is possible to write a seed value into PSA Signature Register before the bus snooping takes place. During data trace mode, all interrupts and DMA request logic are inactive. For non double word read on the data bus, all un-selected byte lanes are padded with zero during compression.

### 14.2.12 Power Down Mode

CRC module can be put into power down mode when the power down control bit PWDN is set. The module wakes up when the PWDN bit is cleared. When CRC controller is in power down mode, no data tracing alone will happen. However, if CRC registers are accessed then data trace happens from channel 1.

### 14.2.13 Emulation

A read access from a register in functional mode can sometimes trigger a certain internal event to follow. For example, reading an interrupt offset register triggers an event to clear the corresponding interrupt status flag. During emulation when SUSPEND signal is high, a read access from any register should only return the register contents to the bus and should not trigger or mask any event as it would have in functional mode. This is to prevent debugger from reading the interrupt offset register during refreshing screen and cause the corresponding interrupt status flag to get cleared. Timeout counters are stopped to generate timeout interrupts in emulation mode. No Peripheral Master bus error should be generated if reading from the unimplemented locations. When channel 1 is placed under data trace, the PSA Signature Register does not compress any data read on CPU data bus when suspend is active.

### 14.2.14 Peripheral Bus Interface

CRC is a Peripheral slave module. The register interface is similar to other peripheral modules. CRC supports following features:

- Different sizes of burst operation.
- Aligned and unaligned accesses.
- Abort is generated for any illegal address accesses.

## 14.3 Example

This section illustrates several of the ways in which the CRC Controller can be utilized to perform CRC.

### 14.3.1 Example: Auto Mode Using Time Based Event Triggering

A large memory area with 2Mbyte (256k doubleword) is to be checked in the background of CPU. CRC is to be performed every 1K byte (128 doubleword). Therefore there should be 2048 pre-recorded CRC values. For illustration purpose, we map channel 1 CRC Value Register to DMA channel 1 and channel 1 PSA Signature Register to DMA channel 2. Assume all DMA transfers are carried out in 64-bit transfer size.

#### 14.3.1.1 DMA Setup

- Set up DMA channel 1 with the starting address from which the pre-determined CRC values are stored. Set up the destination address to the memory mapped channel 1 CRC Value Register. Put the source address at post increment addressing mode and put the destination address at constant addressing mode. Use **hardware** DMA request for channel 1 to trigger a **frame** transfer.
- Set up DMA channel 2 with the source address from which the contents of memory to be verified. Set up the destination address to the memory mapped channel 1 PSA Signature Register. Program the element transfer count to 128 and the frame transfer count to 2048. Put the source address at post increment addressing mode and put the destination address at constant address mode. Use **hardware** DMA request for channel 2 to trigger an entire **block** transfer.

#### 14.3.1.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time-based DMA request.

- Set up timer to generate DMA request associated with DMA channel 2. For example, an OS can set up the timer to generate a DMA request every 10ms.

### 14.3.1.3 CRC Setup

- Program the pattern count to 128.
- Program the sector count to 2048.
- For example, we want the entire 2Mbytes to be compressed within 5ms. We can program the block complete timeout pre-load (CRC\_BCTOPLDx) value to 15625 (5 ms / (1 HCLK period × 64)) if CRC is operating at 200 MHz.
- Enable AUTO mode and all interrupts.

After AUTO mode is selected, CRC Controller automatically generates a DMA request on channel 1. Around the same time the timer module also generates a DMA request on DMA channel 2. When the first incoming data pattern arrives at the PSA Signature Register, the CRC Controller will compress it. After some time, the DMA controller would update the CRC Value Register with a pre-determined value matching the calculated signature for the first sector of 128 64 bit data patterns. After one sector of data patterns are compressed, the CRC Controller generate a CRC fail interrupt if signature stored at the PSA Sector Signature Register does not match the CRC Value Register. CRC Controller generates a DMA request on DMA channel 1 when one sector of data patterns are compressed. This routine will continue until the entire 2Mbyte are consumed. If the timeout counter reached zero before the entire 2Mbytes are compressed a timeout interrupt is generated. After 2MBytes are transferred, the DMA can generate an interrupt to CPU. The entire operation will continue again when DMA responds to the DMA request from both the timer and CRC Controller. The CRC is performed totally without any CPU intervention.

### 14.3.2 Example: Auto Mode Without Using Time Based Triggering

A small but highly secured memory area with 1kbytes is to be checked in the background of CPU. CRC is to be performed every 1Kbytes. Therefore there is only one pre-recorded CRC value. For illustration purpose, we map channel 1 CRC Value Register to DMA channel 1 and channel 1 PSA Signature Register to DMA channel 2. Assume all transfers carried out by DMA are in 64 bit transfer size.

#### 14.3.2.1 DMA Setup

- Set up DMA channel 1 with the source address from which the pre-determined CRC value is stored. Set up the destination address to the memory mapped channel 1 CRC Value Register. Put the source address at constant addressing mode and put the destination address at constant addressing mode. Use **hardware** DMA request for channel 1.
- Set up DMA channel 2 with the source address from which the memory area to be verified. Set up the destination address to the memory mapped channel 1 PSA Signature Register. Program the element transfer count to 128 and the frame transfer count to 1. Put the source address at post increment addressing mode and put the destination address at constant address mode. Generate a **software** DMA request on channel 2 after CRC has completed its setup. Enable autoinitiation for DMA channel 2.

#### 14.3.2.2 CRC Setup

- Program the pattern count to 128.
- Program the sector count to 1.
- Leaving the timeout count register with the reset value of zero means no timeout interrupt is generated.
- Enable AUTO mode and all interrupts.

After AUTO mode is selected, the CRC Controller automatically generates a DMA request on channel 1. At the same time the CPU generates a **software** DMA request on DMA channel 2. When the first incoming data pattern arrives at the PSA Signature Register, the CRC Controller will compress it. After some time, the DMA controller would update the CRC Value Register with a pre-determined value matching the calculated signature for the first sector of 128 64 bit data patterns. After one sector of data patterns are compressed, the CRC Controller generates a CRC fail interrupt if signature stored at the PSA Sector Signature Register does not match the CRC Value Register. CRC Controller generates a DMA request on DMA channel 1 again after one sector is compressed. After 1kbytes are transferred, the DMA can generate an interrupt to CPU. Responding to the DMA interrupt CPU can restart the CRC routine by generating a software DMA request onto channel 2 again.

### 14.3.3 Example: Semi-CPU Mode

If DMA controller is available in a system, the CRC module can also operate in semi-CPU mode. This means that CPU can still make use of the DMA to perform data patterns transfer to CRC controller in the background. The difference between semi-CPU mode and AUTO mode is that CRC controller does not automatically perform the signature verification. CRC controllers generates a compression complete interrupt to CPU when the one sector of data patterns are compressed. CPU needs to perform the signature verification itself.

A memory area with 2Mbyte is to be verified with the help of the CPU. CRC operation is to be performed every 1K byte. Since there are 2Mbyte (256k doublewords) of memory to be check and we want to perform a CRC every 1Kbyte (128 doublewords) and therefore there should be 2048 pre-recorded CRC values. In Semi-CPU mode, the CRC Value Register is not updated and contains indeterminate data.

#### 14.3.3.1 DMA Setup

Set up DMA channel 1 with the source address from which the memory area to be verified are mapped. Set up the destination address to the memory mapped channel 1 PSA Signature Register. Put the starting address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request to trigger an entire block transfer for channel 1. Disable autoinitiation for DMA channel 1.

#### 14.3.3.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time based DMA request.

Set up timer to generate DMA request associated with DMA channel 1. For example, an OS can set up the timer to generate a DMA request every 10ms.

#### 14.3.3.3 CRC Setup

- Program the pattern count to 128.
- Program the sector count to 2048.
- For example, we want the entire 2Mbytes to be compressed within 5ms. We can program the block complete timeout pre-load value to 15625 ( $5 \text{ ms} / (1 \text{ HCLK period} \times 64)$ ) if CRC is operating at 200 MHz.
- Enable Semi-CPU mode and enable all interrupts.

The timer module first generates a DMA request on DMA channel 1 when it is enabled. When the first incoming data pattern arrives at the PSA Signature Register, the CRC controller will compress it. After one sector of data patterns are compressed, the CRC controller generate a compression complete interrupt. Upon responding to the interrupt the CPU would read from the PSA Sector Signature Register. It is up to the CPU on how to deal with the PSA value just read. It can compare it to a known signature value or it can write it to another memory location to build a signature file or even transfer the signature out of the device via SCI or SPI. This routine will continue until the entire 2Mbyte are consumed. The latency of the interrupt response from CPU can cause overrun condition. If CPU does not read from PSA Sector Signature Register before the PSA value is overridden with the signature of the next sector of memory, an overrun interrupt will be generated by CRC controller.

### 14.3.4 Example: Full-CPU Mode

In a system without the availability of DMA controller, the CRC routine can be operated by CPU provided the CPU has enough throughput. CPU needs to read from the memory area from which CRC is to be performed.

A memory area with 2Mbyte is to be checked with the help of the CPU. CRC verification is to be performed every 1K byte. In CPU mode, the CRC Value Register is not updated and contains indeterminate data.

#### 14.3.4.1 CRC Setup

- All control registers can be left in their reset state. Only enable Full-CPU mode.

CPU itself reads from the memory and write the data to the PSA Signature Register inside CRC Controller. When the first incoming data pattern arrives at the PSA Signature Register, the CRC Controller will compress it. After **2MBytes** data patterns are compressed, CPU can read from the PSA Signature Register. It is up to the CPU on how to deal with the PSA signature value just read. It can compare it to a known signature value stored at another memory location.

### 14.4 CRC Control Registers

All registers are in word boundary. 64, 32, 16, and 8 bit write accesses are supported to all registers.

**Table 14-4. CRC Control Registers**

| Offset | Acronym            | Register Description                                    | Section                         |
|--------|--------------------|---------------------------------------------------------|---------------------------------|
| 0h     | CRC_CTRL0          | CRC Global Control Register                             | <a href="#">Section 14.4.1</a>  |
