| 8     | CORL      | 0     | Continue On Request Lost Error                                                                                                                                                                                                          |
|       |           | 0     | Stop current frame on request lost detection. Please see Conditions for Frame Transfer Interruption                                                                                                                                     |
|       |           | 1     | If CORL is one and DCP x is enabled, then DCP x will stay enabled after a request lost condition on DCP x and element transfers will continue.                                                                                          |
| 7-1   | Reserved  | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                  |
| 0     | RLINTENA  | 0     | Request Lost Interrupt Enable Bit                                                                                                                                                                                                       |
|       |           | 0     | The request lost interrupt is disabled for all DCPs. Disabling RLINTENA will not clear the flags in the RLOSTFL register.                                                                                                               |
|       |           | 1     | The request lost interrupt is enabled for all DCPs. If bits are set in the RLOSTFL flag register at the time RLINTENA is (re-) enabled, then the according interrupt(s) will occur (in the order of the priority of the request lines). |

### 24.4.9 Buffer Full Interrupt Enable Set Register (HTU BFINTS)

This registers allows to enable the buffer full interrupts for the different control packets. Reading registers BFINTS and BFINTC will return the same bits indicating the status which interrupt is enabled (1) or disabled (0).

**Figure 24-22. Buffer Full Interrupt Enable Set Register (HTU BFINTS) [offset = 24h]**

**Table 24-21. Buffer Full Interrupt Enable Set Register (HTU BFINTS) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                              |
|-------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                   |
| 15-0  | BFINTENA | 0     | Bus Full Interrupt Enable Bits. If the interrupt for CP A of a DCP is enabled, then the interrupt is generated once buffer A is full, that is, once the frame counter CFTCTA decrements to zero. The same applies for CP B (and CFTCTB). |
|       |          | 1     | Interrupt disabled. Writing a zero has no effect.                                                                                                                                                                                        |
|       |          |       | Writing to bit (2*x) enables the interrupt for CP A of DCP x.                                                                                                                                                                            |
|       |          |       | Writing to bit (2*x+1) enables the interrupt for CP B of DCP x.                                                                                                                                                                          |

### 24.4.10 Buffer Full Interrupt Enable Clear Register (HTU BFINTC)

This registers allows to disable the buffer full interrupts for the different control packets. Reading registers BFINTS and BFINTC will return the same bits indicating the status which interrupt is enabled (1) or disabled (0)

**Figure 24-23. Buffer Full Interrupt Enable Clear Register (HTU BFINTC) [offset = 28h]**

### 24.4.12 Interrupt Offset Register 0 (HTU INTOFF0)

The INTOFF0 register reflects the highest priority interrupt flag bit set in the BERINTFL, RLOSTFL or BFINTFL flag registers with the appropriate CPINTMAP bit set to 0. The priority order (from high to low) is: BER, RLOST, buffer-full. Interrupts for request lines with lower number (higher row in the table next page) have higher priority.

**NOTE:** Reading CPOFF0 will clear the bit generating the current interrupt from appropriate flag register (BERINTFL, RLOSTFL, or BFINTFL) except when in debug mode where reading CPOFF0 will have no effect on the flag registers.

**NOTE:** In order to read INTTYPE0 and CPOFF0 simultaneously always read this register using word or half-word but not using byte accesses.

### 24.4.13 Interrupt Offset Register 1 (HTU INTOFF1)

This register is organized identically to the INTOFF0 register. The difference is that INTOFF1 reflects the highest priority interrupt flag bit set in the BERINTFL, RLOSTFL or BFINTFL flag registers with the appropriate CPINTMAP bit set to 1.

**Figure 24-26. Interrupt Offset Register 1 (HTU INTOFF1) [offset = 38h]**

**NOTE:** Reading CPOFF1 will clear the bit generating the current interrupt from appropriate flag register BERINTFL, RLOSTFL, or BFINTFL except when in debug mode where reading CPOFF1 will have no effect on the flag registers.

**NOTE:** In order to read INTTYPE1 and CPOFF1 simultaneously always read this register using word or half-word but not using byte accesses.

#### 24.4.14 Buffer Initialization Mode Register (HTU BIM)

This register enables special applications, where one CP is temporarily disabled, but after having re-enabled the CP, filling the buffer should not start back at its beginning, but should continue after the last element of the previous run.

**Figure 24-27. Buffer Initialization Mode Register (HTU BIM) [offset = 3Ch]**

| E    | 00                                     | 01                       | Enable CP A                        | Next frame starts at the <b>initial</b> address of buffer A         | Next frame continues at the <b>current</b> address of buffer A |
| F    | 00                                     | 10                       | Enable CP B                        | Next frame starts at the <b>initial</b> address of buffer B         | Next frame continues at the <b>current</b> address of buffer B |
| G    | xx                                     | 11                       | Disable both CPs                   | Stop DCP x                                                          | Same as for BIM bit x = 0                                      |

<sup>(1)</sup> See read table of CPENA register.

<sup>(2)</sup> See write table of CPENA register.

<sup>(3)</sup> This is regardless of whether the switch is done by a write access to CPENA or by the auto switch feature.

---

**NOTE:** For cases E and F above, after the last frame of a buffer, the HTU sets CFTCTx to zero and CFADDRx to the next address after the buffer. If the DCP was disabled during this state, then both CFTCTx and CFADDRx would contain invalid initialization values. Therefore, if a DCP should continue at its current address, then the software should use one of the following two procedures before it (re-) enables the DCP (as per [Table 24-27](#)):

1. If CFTCTx  $\neq$  0 then set BIM=1  
     If CFTCTx = 0 then set  
         BIM=0
2. If CFTCTx  $\neq$  0 then set  
     BIM=1  
     If CFTCTx = 0 then {set  
         BIM=1;

```
set CFTCTx = IFTCOUNT;
set CFADDRx = IFADDRx}
```

But note that these procedures are only required for the cases E and F and not for all the other cases shown in the table. Also, when a buffer reaches its end in circular mode, it uses the initial DCP information to restart independently of the BIM setting (assuming it is not temporarily disabled during CFTCTx = 0).

---

**NOTE:** Similarly, care needs to be taken when BIM is set to one and a DCP is enabled for the very first time. Also, in this case, CFTCTx and CFADDRx usually contain invalid initialization values. The software can either solve this by setting BIM=0 for the first time or setting CFADDRx to IFADDRx and CFTCTx to IFTCOUNT before the DCP is enabled.

---

**NOTE:** If

- the HTUEN bit is changed to one after the HTU was disabled HTUEN=0
- the CPENA bit pair is 01 or 10 (during this HTUEN change)

then the corresponding BIM bit will decide if the corresponding buffer continues at its initial or current address. Cases E and F in [Table 24-27](#) also apply for this situation. The software should use the procedures explained in the first note before setting HTUEN.

---

| 15-0  | BFINTFL  | 0     | Buffer Full Interrupt Flags                                                                                                                                                                                                                                                                                                                                                                         |
|       |          | 0     | No buffer full condition detected. Writing a zero has no effect.                                                                                                                                                                                                                                                                                                                                    |
|       |          | 1     | If bit (2*x) is set, a buffer full condition on CP A of DCP x has been detected.<br>If bit (2*x+1) is set, a buffer full condition on CP B of DCP x has been detected.                                                                                                                                                                                                                              |
|       |          |       | The BFINTFL flag is set after the last frame finishes on the corresponding buffer regardless of whether the buffer is configured to one shot, circular or auto-switch mode. If BFINTFL is set in circular mode, then a circular overrun has occurred on the corresponding buffer. This can be used to indicate whether the buffer section after the frozen full address contains valid data or not. |
|       |          |       | Reading from INTOFFx in case of a buffer-full interrupt clears the corresponding flag. The state of the flag bit can be polled even if the corresponding interrupt enable bit is cleared.                                                                                                                                                                                                           |

### 24.4.17 BER Interrupt Flag Register (HTU BERINTFL)

A bus error interrupt results due to an address error or a timeout condition on the main memory access. A bus error will stop the frame transfer. Please see [Section 24.2.3](#).

| Bit  | Field       | Value | Description                                                                                                                                                                                                            |
|------|-------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ENDADDRESS1 |       | The end address defines at which address the region ends. A memory protection error will be triggered, if the HTU accesses an address bigger than ENDADDRESS1 and the register bit REG01ENA is configured accordingly. |

## 24.4.20 Debug Control Register (HTU DCTRL)

This register allows to create watchpoints on access to a certain location. It is intended to help debug the application execution during program development.

**Figure 24-33. Debug Control Register (HTU DCTRL) [offset = 54h]**

|          |    |       |    |          |    |         |   |

### 24.4.21 Watch Point Register (HTU WPR)

This register defines the main memory address of the watchpoint.

**Figure 24-34. Watch Point Register (HTU WPR) [offset = 58h]**

LEGEND: R/W = Read/Write; R = Read only; WS = Write in suspend mode only; -n = value after reset

**Table 24-34. Watch Point Register (HTU WPR) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------|-------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | WP    |       | <p>Watch Point Register</p> <p>A 32-bit address can be programmed into this register as a watch point. The WPR register is used along with the Watch Mask Register ( WMR). When the main memory address is equal to the unique address defined by WPR, or lies in the specified range resulting from WMR, then the HTUDBGS is set. If in addition DBREN is set, then the application code execution is stopped.</p> <p>This register can only be programmed during debug mode. This register and all other bits of the DCTRL and WMR registers are reset by the test reset (nTRST) but not by the normal device reset.</p> |

### 24.4.22 Watch Mask Register (HTU WMR)

This register defines a mask of the main memory address of the watchpoint. It can be used to define a memory range in conjunction with the WPR register.

**Figure 24-35. Watch Mask Register (HTU WMR) [offset = 5Ch]**

LEGEND: R/W = Read/Write; R = Read only; WS = Write in suspend mode only; -n = value after reset

**Table 24-35. Watch Mask Register (HTU WMR) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                              |

| 31-0 | WM    |       | <p>Watch Mask Register</p> <p>Setting a bit in the WMR register to one has the effect of masking the corresponding bit in of the main memory address, so that this bit is ignored for the address comparison.</p> <p>This register can only be programmed during debug mode. This register and all other bits of the DCTRL and WPR registers are reset by the test reset (nTRST) but not by the normal device reset.</p> |

### 24.4.23 Module Identification Register (HTU ID)

This register is for TI internal purposes and allows to keep track of the HTU module version on different devices.

**Figure 24-36. Module Identification Register (HTU ID) [offset = 60h]**

LEGEND: R = Read only; -n = value after reset

**Table 24-36. Module Identification Register (HTU ID) Field Descriptions**

Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 16    | COPE       | 0          | Continue on Parity Error<br>The HTU performs parity checks every time it reads the RAM section of DCP x (with x = 0, 1,... or 7), before the next frame (of DCP x) is started. If a parity error is detected during this read access and if the parity check is enabled, then the frame will not be started and DCP x will be automatically disabled in the CPENA register.<br><br>If a master different than the HTU (for example, CPU) reads the RAM section of DCP x and a parity error is detected during this read access, while the parity check is enabled, then the DCP x will automatically be disabled in the CPENA register. If a frame is active on DCP x during this read access, then in addition the element counter of DCP x is cleared and all new element transfers on DCP x are stopped and the active busy bit of DCP x is cleared. |
|       |            | 1          | The difference to COPE=0 is, that the data transfer on a active DCP continues after a parity error was detected on this DCP. So neither the DCP with the parity error will be disabled nor the frame will be stopped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                    |

**Table 24-39. Memory Protection Control and Status Register (HTU MPCS) Field Descriptions (continued)**

| Bit | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----|----------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | INTENA01 | 0<br>1 | Interrupt Enable 01. This bit needs to be set when working with two memory mapped regions and a error should be generated to the ESM module on an access violation.<br>Error signalling is disabled<br>Error signalling is enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 4   | ACCR01   | 0<br>1 | Access Rights 01. This bit defines the access rights for the HTU for accesses outside the region defined by the MP0S and MP0E and the MP1S and MP0E registers.<br>HTU read access is allowed but write access will be signaled<br>Any access performed by the HTU is forbidden and will be signaled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 3   | REG01ENA | 0<br>1 | Region Enable 01. This bit needs to be set when working with two memory mapped regions. <b>REG0ENA must be set to zero</b> if this bit is set to a one. Memory region 0 must be less than memory region 1.<br>The protection outside the memory region defined by the MP0S and MP0E and the MP1S and MP0E registers is not enabled. This means the HTU can access any implemented memory space. REG0ENA could still enabled to give protection outside the MP0S : MP0E region.<br>The protection outside the memory region defined by the MP0S and MP0E and the MP1S and MP0E registers is enabled. This means the HTU can perform any access within the regions, but if it attempts to perform a forbidden access outside of both of the regions (according to the ACCR01 configuration), the access is signaled by the MPEFT1 flag. The number of the CP, which has caused the memory protection error, is captured to CPNUM1 if it is not currently frozen and an error is generated if it is enabled. |
| 2   | INTENA0  | 0<br>1 | Interrupt Enable 0. This bit needs to be set when working with one memory mapped region and a error should be generated to the ESM module on an access violation.<br>Error signalling is disabled<br>Error signalling is enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 1   | ACCR     | 0<br>1 | Access Rights 0. This bit defines the access rights for the HTU for accesses outside the region defined by the MP0S and MP0E registers for a single memory protection region configuration.<br>HTU read access is allowed but write access will be signaled<br>Any access performed by the HTU is forbidden and will be signaled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 0   | REG0ENA  | 0<br>1 | Region Enable 0<br>The protection outside the memory region defined by the MP0S and MP0E registers is not enabled. This means the HTU can access any implemented memory space.<br>The protection outside the memory region defined by the MP0S and MP0E registers is enabled. This means the HTU can perform any access within the region, but if it attempts to perform a forbidden access outside the region (according to the ACCR configuration), the access is signaled by the MPEFT0 flag, the number of the CP, which has caused the memory protection error, is captured to CPNUM0 if it is not currently frozen and an error is generated if it is enabled.                                                                                                                                                                                                                                                                                                                                      |

### 24.4.27 Memory Protection Start Address Register 0 (HTU MP0S)

This register configures the start address of memory protection region 0

**Figure 24-40. Memory Protection Start Address Register 0 (HTU MP0S) [offset = 74h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

**Table 24-40. Memory Protection 0 Start address Register (HTU MP0S) Field Descriptions**

| Bit  | Field          | Value | Description                                                                                                                                                                                                                       |
|------|----------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ISTARTADDRESS0 |       | The start address defines at which main memory address the region begins. A memory protection error will be triggered, if the HTU accesses an address smaller than STARTADDRESS0 and the MPCS register is configured accordingly. |

### 24.4.28 Memory Protection End Address Register (HTU MP0E)

**Figure 24-41. Memory Protection End Address Register (HTU MP0E) [offset = 78h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

**Table 24-41. Memory Protection End Address Register (HTU MP0E) Field Descriptions**

| Bit  | Field       | Value | Description                                                                                                                                                                                                                 |
|------|-------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ENDADDRESS0 |       | The end address defines at which address the region ends. A memory protection error will be triggered, if the HTU accesses an address bigger than ENDADDRESS0 and the register bit MPCS register is configured accordingly. |

## 24.5 Double Control Packet Configuration Memory

All bits marked "reserved" are implemented in RAM and will be initialized to unknown values after power on. Reserved locations can be written and read but should be written with zero to ensure future compatibility. The HTU RAM can be cleared with the system RAM initialization function.

[Table 24-42](#) provides a summary of the memory configuration. There are eight sets of DCP registers and eight sets of CF registers. The base address for DCPs is FF4E 0000h.

If the NHET address points to the Program Field (PF), then the PF and CF will be transferred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 21    | ADDMH    | 0<br>1                | Addressing Mode NHET Address. This bit determines the NHET address index from one to the next element of a frame.<br>Increment by 16 bytes<br><b>Examples:</b><br>If the initial NHET address points to data field of instruction (n). Then the NHET fields to be transferred by the elements of a frame are: data field of instruction (n), data field of instruction (n+1), data field of instruction (n+2) and so on. If the initial NHET address points to control field of instruction (n), then the NHET fields to be transferred by the elements of a frame are: control field of instruction (n), control field of instruction (n+1), control field of instruction (n+2) and so on.<br>Increment by 8 bytes<br>This mode is intended to be used together with the 64-bit transfer size to load short NHET instruction blocks into the NHET RAM. So the sequence of transferred 64-bit elements could be: [PF and CF of instruction (n)], [DF and RF of instruction (n)], [PF and CF of instruction (n+1)], [DF and RF of instruction (n+1)] and so on. |

|------|---------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CFADDRA |       | <p>Current (byte) Address of Buffer A</p> <p>The current main memory address register is updated at the end of each frame. Therefore it points to the start address of the frame, which is the next to transfer, if currently no frame is transferred on this DCP. For an ongoing frame transfer, it points to the start address of this frame. After the last element of a buffer was transferred it will point to the buffer end address plus 0x4.</p> <p>The main purpose of the current full address registers for buffer A and buffer B (see next section) is to enable the software to find out the recently transferred element in the frozen buffer while the address of the active buffer increments.</p> <p><b>Note:</b> A frame can be automatically stopped if any of the events listed in Conditions for Frame Transfer Interruption happens. If a frame is stopped before it could complete, then the current full address register is not updated and it will point to the start of the bad frame after the DCP was automatically disabled.</p> |

To transfer the first frame of buffer x, the information in the corresponding initial DCP RAM (IFADDRx, IHADDRCT, ITCOUNT) is loaded to an internal state machine but not to the current DCP RAM (CFADDRx, CFTCTx).

This is valid for all of the following modes:

- Buffer x has reached its end in circular mode and rolls back to its start address.
- CP x is enabled by a CPENA access (and corresponding BIM bit is zero).
- A CPENA access or auto-switch mode causes a switch from CP y to CP x

This means after starting the transfer to/from buffer x, CFADDRx and CFTCTx is not updated before the end of the first frame. So before the software switches from CP y to CP x using a write access to the CPENA register, it needs to initialize CFADDRx, CFTCTx. This allows the software to find out if the next request on CP x after the switching to CP x was delayed or never occurring.

## 24.5.6 Current Full Address B Register (HTU CFADDRB)

| Bit  | Field   | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------|---------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | CFADDRB |       | <p>Current (byte) Address of Buffer B</p> <p>The current main memory address register is updated at the end of each frame. Therefore it points to the start address of the frame, which is the next to transfer, if currently no frame is transferred on this DCP. If currently a frame is transferred, then it points to the start address of this frame. After the last element of a buffer was transferred it will point to the buffer end address plus 0x4.</p> <p>The main purpose of the current full address registers for buffer A and buffer B (see next section) is to enable the software to find out the recently transferred element in the frozen buffer while the address of the active buffer increments.</p> <p><b>Note:</b> A frame can be automatically stopped if any of the events listed in Conditions for Frame Transfer Interruption happens. If a frame is stopped before it could complete, then the current full address register is not updated and it will point to the start of the bad frame after the DCP was automatically disabled.</p> |

To transfer the first frame of buffer x, the information in the corresponding initial DCP RAM (IFADDRx, IHADDRCT, ITCOUNT) is loaded to an internal state machine but not to the current DCP RAM (CFADDRx, CFTCTx).

This is valid for all of the following modes:

- Buffer x has reached its end in circular mode and rolls back to its start address.
- CP x is enabled by a CPENA access (and corresponding BIM bit is zero).
- A CPENA access or auto-switch mode causes a switch from CP y to CP x

This means after starting the transfer to/from buffer x, CFADDRx and CFTCTx is not updated before the end of the first frame. So before the software switches from CP y to CP x using a write access to the CPENA register, it needs to initialize CFADDRx, CFTCTx. This allows the software to find out if the next request on CP x after the switching to CP x was delayed or never occurring.

### 24.5.7 Current Frame Count Register (HTU CFCOUNT)

The current frame count register enables the software to find out the recent element in the frozen buffer while the counter of the active buffer decrements.

**Figure 24-48. Current Frame Count Register (HTU CFCOUNT)**

**Table 24-49. Initial Transfer Count Register (HTU CFCOUNT) Field Descriptions**

| Bit   | Field    | Value | Description                                                                    |
|-------|----------|-------|--------------------------------------------------------------------------------|
| 31-24 | Reserved | 0     | Read returns 0. Writes have no effect.                                         |
| 23-16 | CFTCTA   |       | Current Frame Transfer Count for CP A. It is updated at the end of each frame. |
| 15-8  | Reserved | 0     | Read returns 0. Writes have no effect.                                         |
| 7-0   | CFTCTB   |       | Current Frame Transfer Count for CP B. It is updated at the end of each frame. |

## 24.6 Examples

### 24.6.1 Application Examples for Setting the Transfer Modes of CP A and B of a DCP

**Table 24-50. Application Examples for Setting the Transfer Modes of CP A and B of a DCP**

| CP A        | CP B        |                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| One shot    | Not used    | Buffer A can be used as a "one shot" buffer. A buffer full interrupt enabled for CP A can signal reaching the end of the buffer.                                                                                                                                                                                                                                                                                  |
| Auto switch | One shot    | Can double the buffer size for a "one shot" buffer. A buffer full interrupt enabled for CP B can signal reaching the end of the buffer.                                                                                                                                                                                                                                                                           |
| Circular    | Circular    | The CPU can switch the buffers at arbitrary times. It will fill or read the frozen buffer during the other buffer is filled or read by the HTU. Interrupts are not required for this case.                                                                                                                                                                                                                        |
| Auto switch | Auto switch | Buffer full interrupts (enabled for CP A and B) signal when the end of a buffer is reached. After one buffer is completed the according CPU interrupt routine will read or refill this buffer. At the same time the other buffer is read or filled by the HTU. Here the time when the buffer must be read is determined by the time of the interrupt (determined by the frequency of the NHET transfer requests). |

### 24.6.2 Software Example Sequence Assuming Circular Mode for Both CP A and B

The example assumes the NHET address to be read and the main memory address to be written.

- I1 CPU initializes initial DCP: IFADDRA, IFADDRB, IHADDRCT, ITCOUNT
- I2 CPU clears current DCP: CFADDRA, CFADDRB, CFTCTA, CFTCTB
- I3 CPU clears BFINTFL flag of CP A and B
- I4 Enable CP A with the CPENA register. Now the HTU fills buffer A

After some time the CPU intends to read buffer A:

- A1 CPU enables CP B and disables CP A by writing to the CPENA register. After this switch, the HTU fills buffer B. Filling buffer B starts with its initial full address and initial frame counter
- A2 CPU waits for CP A busy bit equals zero
- A3 Optional: CPU verifies that the CP A request lost flag is not set. The bus error flag of CP A could also be checked
- A4 CPU reads the frozen CFTCTA, which indicates the fill level in the buffer
- A5 CPU sets current CP A (CFTCTA and/or CFADDRA) to zero. This allows to find out if any request has happened during the next time buffer A is active
- A6 CPU reads BFINTFL flag of buffer A
- A7 CPU clears the BFINTFL flag of buffer A. This is an initialization for the next time buffer A is used
- A8 CPU reads valid values of frozen buffer A. After reading the CPU does not need to clear the frozen buffer A

After some time the CPU intends to read buffer B:

- |    |                                                                                                                                                                                                 |
|----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| B1 | CPU enables CP A and disables CP B by writing to the CPENA register. After this switch, the HTU fills buffer A. Filling buffer A starts with its initial full address and initial frame counter |
| B2 | CPU waits for CP B busy bit equals zero                                                                                                                                                         |
| B3 | Optional: CPU verifies that the CP B request lost flag is not set. The bus error flag of CP B could also be checked                                                                             |
| B4 | CPU reads the frozen CFTCTB, which indicates the fill level in the buffer                                                                                                                       |
| B5 | CPU sets current CP B (CFTCTB and/or CFADDRB) to zero. This allows to find out if any request has happened during the next time buffer B is active                                              |
| B6 | CPU reads BFINTFL flag of buffer B                                                                                                                                                              |
| B7 | CPU clears the BFINTFL flag of buffer B. This is an initialization for the next time buffer B is used                                                                                           |
| B8 | CPU reads valid values of frozen buffer B. After reading the CPU does not need to clear the frozen buffer B                                                                                     |

After some time the CPU intends to read buffer A:

A1) ... see above...

---

**NOTE:** The buffer full interrupt doesn't need to be enabled. The BFINTFL flag is used to indicate a circular overrun of the buffer. If the BFINTFL flag is set, also the buffer section after the frozen full address could be read.

---

Steps A3 and B3 in the example sequence above imply that request lost interrupts are disabled. The example below assumes that request lost interrupts are enabled.

Request lost detection with interrupt enabled.

### 24.6.3 Example of an Interrupt Dispatch Flow for a Request Lost Interrupt

- A request lost occurs and the interrupt routine starts.
- Reading INTOFFx.INTYPEx shows that RLOSTFL is the interrupt source.
- Reading INTOFFx.CPOFFx = Ah shows that DCP 5 / CP A has caused the RLOSTFL interrupt. The hardware automatically clears bit (2·5+0) in RLOSTFL.
- Reading RLOSTFL= 84h shows that also another request lost event happened on DCP 1 / CP A [bit (2·1+0)] and on DCP 3 / CP B [bit (2·3+1)] at the same time or after the request lost occurred on DCP 5 / CP A.
- Writing back 84h to RLOSTFL clears bits 2 and 7 and the according pending interrupts.

## ***General-Purpose Input/Output (GPIO) Module***

This chapter describes the general-purpose input/output (GPIO) module. The GPIO module provides the family of devices with input/output (I/O) capability. The I/O pins are bidirectional and bit-programmable. The GPIO module also supports external interrupt capability.

| Topic                                                   | Page                        |

## 25.1 Overview

The GPIO module offers general-purpose input / output capability. It supports up to eight 8-bit ports for a total of up to 64 GPIO terminals. Each of these 64 terminals can be independently configured as input or output and configured as required by the application. The GPIO module also supports generation of interrupts whenever a rising edge or falling edge or any toggle is detected on up to 32 of these GPIO terminals. Refer to the device datasheet for identifying the number of GPIO ports supported and the GPIO terminals capable of generating an interrupt.

**Figure 25-1. GPIO Block Diagram**

The main features of the GPIO module are summarized as follows:

- Allows each GPIO terminal to be configured for general-purpose input or output functions
- Supports programmable pull directions on each input GPIO terminal
- Supports GPIO output in push/pull or open-drain modes
- Allows up to 32 GPIO terminals to be used for generating interrupt requests

## 25.2 Quick Start Guide

The GIO module comprises two separate components: an input/output (I/O) block and an interrupt generation block. [Figure 25-2](#) and [Figure 25-3](#) show what the user should do after reset to configure the GIO module as I/O or for generating interrupts.

**Figure 25-2. I/O Function Quick Start Flow Chart**

**Figure 25-3. Interrupt Generation Function Quick Start Flow Chart**

In GPIO interrupt service routine, user shall read the GPIO offset register [GIOFFA](#) / [GIOFFB](#) (depending on high/low level interrupt) to clear the flag and find the pending interrupt GPIO channel.

## 25.3 Functional Description of GIO Module

As shown earlier in [Figure 25-1](#) the GIO module comprises of two separate components: an input/output (I/O) block and an interrupt block.

### 25.3.1 I/O Functions

The I/O block allows each GIO terminal to be configured for use as a general-purpose input or output in the application. The GIO module supports multiple registers to control the various aspects of the input and output functions. These are described as follows.

- Data direction ( [GIODIR](#) )  
Configures GIO terminal(s) as input or output through the GIODIRx registers.
- Data input ( [GIODIN](#) )  
Reflects the logic level on GIO terminals in the GIODINx registers. A high voltage ( $V_{IH}$  or greater) applied to the pin causes a high value (1) in the data input register ( [GIODIN\[7:0\]](#) ). When a low voltage ( $V_{IL}$  or less) is applied to the pin, the data input register reads a low value (0). The  $V_{IH}$  and  $V_{IL}$  values are device specific and can be found in the device datasheet.
- Data output ( [GIODOUT](#) )  
Configures the logic level to be output on GIO terminal(s) configured as outputs. A low value (0) written to the data output register forces the pin to a low output voltage ( $V_{OL}$  or lower). A high value (1) written to the data output register ( [GIODOUTx](#) ) forces the pin to a high output voltage ( $V_{OH}$  or higher) if the open drain functionality is disabled ( [GIOPDRx\[7:0\]](#) ). If open drain functionality is enabled, a high value (1) written to the data output register forces the pin to a high-impedance state (Z).
- Data set ( [GIODSET](#) )  
Allows logic HIGH to be output on GIO terminal(s) configured as outputs by writing 1's to the required bits in the GIODSETx registers. If open drain functionality is enabled, a high value (1) written to the data output register forces the pin to a high-impedance state (Z). The GIODSETx registers eliminate the need for the application to perform a read-modify-write operation when it needs to set one or more GIO pin(s).
- Data clear ( [GIODCLR](#) )  
Allows logic LOW to be output on GIO terminal(s) configured as outputs by writing 1s to the required bits in the GIODCLR registers. The GIODCLR registers eliminate the need for the application to perform a read-modify-write operation when it needs to clear one or more GIO pin(s).
- Open drain ( [GIOPDR](#) )  
Open drain functionality is enabled or disabled using the open drain register [GIOPDR\[7:0\]](#) register. If open-drain mode output is enabled on a pin, a high value (1) written to the data output register ( [GIODOUTx\[7:0\]](#) ) forces the pin to a high impedance state (Z).
- Pull disable ( [GIOPULDIS](#) )  
Disables the internal pull on GIO terminal(s) configured as inputs by writing to the [GIOPULDISx](#) registers.
- Pull select ( [GIOSPL](#) )  
Selects internal pull down or pull up on GIO terminal(s) configured as inputs by writing to the [GIOPULSELx](#) registers.

Refer to the specific device's datasheet to identify the number of GIO ports as well as the input and output functions supported. Some devices may not support the programmable pull controls. In that case, the pull disable and the pull select register controls will not work.

### 25.3.2 Interrupt Function

The GIO module supports up to 32 terminals to be configured for generating an interrupt to the host processor through the Vectored Interrupt Manager (VIM). The main functions of the interrupt block are:

- Select the GIO pin(s) that is/are used to generate interrupt(s)  
This is done via the interrupt enable set and clear registers, [GIOENASET](#) and [GIOENACLR](#)
- Select the edge on the selected GIO pin(s) that is/are used to generate interrupt(s): rising/falling/both

Rising or falling edge can be selected via the GIOPOL register ( [GIOPOL](#)). If interrupt is required to be generated on both rising and falling edges, this can be configured via the GIOINTDET register ( [GIOINTDET](#)).

- Select the interrupt priority  
Low or High-level interrupt can be selected through the GIOLVLSET and GIOLVLCLR registers ( [GIOLVLSET](#)) and [GIOLVLCLR](#)).
- Individual interrupt flags are set in the GIOFLG register ([Section 25.5.6](#))

The terminals on GIO ports A through D are all interrupt-capable and can be used to handle either general I/O functions or interrupt requests. Each interrupt request can be connected to the VIM at one of two different levels – High (or A) and Low (or B), depending on the VIM channel number. The VIM has an inherent priority scheme so that a request on a lower number channel has a higher priority than a request on a higher number channel. Refer the device datasheet to identify the VIM channel numbers for the GIO level A and level B interrupt requests. Also note that the interrupt priority of level A and level B interrupt handling blocks can be re-programmed in the VIM.

### 25.3.3 GIO Block Diagram

The GIO block diagram (see [Figure 25-4](#)) represents the flow of information through a pin. The shaded area corresponds to the I/O block; the unshaded area corresponds to the interrupt block.

**Figure 25-4. GIO Block Diagram**

- (1) A single low-level-interrupt-handling block and a single high-level-interrupt-handling block service all of the interrupt-capable external pins, but only one pin can be serviced by an interrupt block at a time.

## 25.4 Device Modes of Operation

The GIO module behaves differently in different modes of operation. There are two main modes:

- Emulation mode
- Power-down mode (low-power mode)

### 25.4.1 Emulation Mode

Emulation mode is used by debugger tools to stop the CPU at breakpoints to read registers.

---

#### NOTE: Emulation Mode and Emulation Registers

Emulation mode is a mode of operation of the device and is separate from the GIO emulation registers (GIOEMU1 and GIOEMU2). The contents of these emulation registers are identical to the contents of GIO offset registers (GIOOFF1 and GIOOFF2). Both emulation registers and GIO offset registers are NOT cleared when they are read in emulation mode. GIO offset registers are cleared when they are read in normal mode (other than emulation mode). The emulation registers are NOT cleared when they are read in normal mode. The intention for the emulation registers is that software can use them without clearing the flags.

---

During emulation mode:

- External interrupts are not captured because the VIM is unable to service interrupts.
- Any register can be read without affecting the state of the system.
- A write to a register still does affect the state of the system.

### 25.4.2 Power-Down Mode (Low-Power Mode)

In the power-down mode, the clock signal to the GIO module is disabled. Thus, there is no switching and the only current draw comes from leakage current. In power-down mode, interrupt pins become level-sensitive rather than edge sensitive. The polarity bit changes function from falling-edge-triggered to low-level-triggered and rising-edge-triggered to high-level-triggered. A corresponding level on an interrupt pin pulls the module out of low-power mode.

#### 25.4.2.1 Module-Level Power Down

The GIO module can be placed into a power down state by disabling the GIO peripheral module via the appropriate bit in the peripheral power down register. Please refer to the Peripheral Central Resource Registers ([Section 2.5.3](#)) for details.

#### 25.4.2.2 Device-Level Power Down

The entire device can be placed in one of the pre-defined low-power modes: doze, snooze, or sleep using the clock source and clock domain disable registers in the system module.

## 25.5 GIO Control Registers

[Table 25-1](#) shows the summary of the GIO registers. The registers are accessible in 8-, 16-, and 32-bit reads or writes.

The start address for the GIO module is FFF7 BC00h.

The GIO module supports up to 8 ports: GIOA, GIOB, GIOC, GIOD, GIOE, GIOF, GIOG, and GIOH. Refer the device datasheet to identify the actual number of GIO ports and the number of pins in each GIO port implemented on this device.

The GIO module supports up to 4 interrupt-capable ports: GIOA, GIOB, GIOC, and GIOD. Refer the device datasheet to identify the actual number of interrupt-capable GIO ports and the number of pins in each GIO port implemented on this device.

**Table 25-1. GIO Control Registers Summary**

| Offset                                                                                          | Acronym        | Register Description                  | Section                          |

### 25.5.1 GIO Global Control Register (GIOGCR0)

The GIOGCR0 register contains one bit that controls the module reset status. Writing a zero (0) to this bit puts the module in a reset state. After system reset, this bit must be set to 1 before normal operations can begin on this module. [Figure 25-5](#) and [Table 25-2](#) describe this register.

**Figure 25-5. GIO Global Control Register (GIOGCR0) [address = FFF7 BC00h]**

|     |          |  |  |  |  |  |  |  |  |  |   |       |        |  |    |
|-----|----------|--|--|--|--|--|--|--|--|--|---|-------|--------|--|----|
| 31  | Reserved |  |  |  |  |  |  |  |  |  |   |       |        |  | 16 |
| R-0 |          |  |  |  |  |  |  |  |  |  |   |       |        |  |    |
| 15  | Reserved |  |  |  |  |  |  |  |  |  | 1 | 0     |        |  |    |
| R-0 |          |  |  |  |  |  |  |  |  |  |   | RESET | R/WP-0 |  |    |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 25-2. GIO Global Control Register (GIOGCR0) Field Descriptions**

| Bit  | Field    | Value | Description                              |
|------|----------|-------|------------------------------------------|
| 31-1 | Reserved | 0     | Read returns 0. Writes have no effect.   |
| 0    | RESET    | 0     | GIO reset.<br>The GIO is in reset state. |
|      |          | 1     | The GIO is operating normally.           |

**NOTE:** Note that putting the GIO module in reset state is not the same as putting it in a low-power state.

### 25.5.2 GIO Interrupt Detect Register (GIOINTDET)

The GIOINTDET register provides the flexibility to either ignore the polarity of the edges that are recognized as an interrupt, in which case both rising and falling edges are recognized, or recognizing the interrupt on specifically a rising or falling edge as determined by the GIOPOL register. To ensure recognition of the signal as an edge, the signal must maintain the new level for at least one VCLK cycle. Figure 25-6 and Table 25-3 describe this register.

**Figure 25-6. GIO Interrupt Detect Register (GIOINTDET) [address = FFF7 BC08h]**

|             |    |             |    |
|-------------|----|-------------|----|

**Table 25-3. GIO Interrupt Detect Register (GIOINTDET) Field Descriptions**

| Bit   | Field       | Value | Description                                                                                                                                     |
|-------|-------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | GIOINTDET 3 |       | Interrupt detection select for pins GIOD[7:0]                                                                                                   |
|       |             | 0     | The flag sets on either a falling or a rising edge on the corresponding pin, depending on the polarity setup in the polarity register (GIOPOL). |
|       |             | 1     | The flag sets on both the rising and falling edges on the corresponding pin.                                                                    |
| 23-16 | GIOINTDET 2 |       | Interrupt detection select for pins GIOC[7:0]                                                                                                   |
|       |             | 0     | The flag sets on either a falling or a rising edge on the corresponding pin, depending on the polarity setup in the polarity register (GIOPOL). |
|       |             | 1     | The flag sets on both the rising and falling edges on the corresponding pin.                                                                    |
| 15-8  | GIOINTDET 1 |       | Interrupt detection select for pins GIOB[7:0]                                                                                                   |
|       |             | 0     | The flag sets on either a falling or a rising edge on the corresponding pin, depending on the polarity setup in the polarity register (GIOPOL). |
|       |             | 1     | The flag sets on both the rising and falling edges on the corresponding pin.                                                                    |
| 7-0   | GIOINTDET 0 |       | Interrupt detection select for pins GIOA[7:0]                                                                                                   |
|       |             | 0     | The flag sets on either a falling or a rising edge on the corresponding pin, depending on the polarity setup in the polarity register (GIOPOL). |
|       |             | 1     | The flag sets on both the rising and falling edges on the corresponding pin.                                                                    |

### 25.5.3 GIO Interrupt Polarity Register (GIOPOL)

The GIOPOL register controls the polarity - rising edge (low to high) or falling edge (high to low) - that sets the flag. To ensure recognition of the signal as an edge, the signal must maintain the new level for at least one VCLK cycle. When the device is in low power mode, the interrupts are no longer triggered by an edge, but instead by a level. Therefore, in low power mode, the GIOPOL register controls the **level**, high or low, which will trigger the interrupt. [Figure 25-7](#) and [Table 25-4](#) describe this register.

**Figure 25-7. GIO Interrupt Polarity Register (GIOPOL) [address = FFF7 BC0Ch]**

|          |    |          |    |
|----------|----|----------|----|
| 31       | 24 | 23       | 16 |
| GIOPOL 3 |    | GIOPOL 2 |    |
| R/W-0    |    | R/W-0    |    |

|       |          | 0     | The flag is set on the falling edge on the corresponding pin.                               |
|       |          | 1     | The flag is set on the rising edge on the corresponding pin.                                |
|       |          |       | Low-power mode (GIO module clocks off):                                                     |
| 23-16 | GIOPOL 2 | 0     | The interrupt is triggered on the low level.                                                |
|       |          | 1     | The interrupt is triggered on the high level.                                               |
|       |          |       | Interrupt polarity select for pins GIOC[7:0]<br>Normal operation (user or privileged mode): |
|       |          | 0     | The flag is set on the falling edge on the corresponding pin.                               |
| 15-8  | GIOPOL 1 | 1     | The flag is set on the rising edge on the corresponding pin.                                |
|       |          |       | Low-power mode (GIO module clocks off):                                                     |
|       |          | 0     | The interrupt is triggered on the low level.                                                |
|       |          | 1     | The interrupt is triggered on the high level.                                               |
| 7-0   | GIOPOL 0 |       | Interrupt polarity select for pins GIOA[7:0]<br>Normal operation (user or privileged mode): |
|       |          | 0     | The flag is set on the falling edge on the corresponding pin.                               |
|       |          | 1     | The flag is set on the rising edge on the corresponding pin.                                |
|       |          |       | Low-power mode (GIO module clocks off):                                                     |
|       |          | 0     | The interrupt is triggered on the low level.                                                |
|       |          | 1     | The interrupt is triggered on the high level.                                               |

## 25.5.4 GIO Interrupt Enable Registers (GIOENASET and GIOENACLR)

The GIOENASET and GIOENACLR registers control which interrupt-capable pins are actually configured as interrupts. If the interrupt is enabled, the rising or falling or both edges on the selected pin lead to an interrupt.

### 25.5.4.1 GIOENASET Register

Figure 25-8 and Table 25-5 describe this register.

#### NOTE: Enabling Interrupt at the Device Level

GIO can be mapped to two different device level interrupts, the GIO high-level (level A) and low-level (level B) interrupts through programming registers GIOLVLSET and GIOLVLCR. The corresponding bit to the mapped device level interrupt must be set within the vectored interrupt manager (VIM) in the interrupt mask register (REQMASK) to enable the appropriate interrupts. Additionally, the ARM CPU (CPSR bit 7 or 6) must be cleared to recognize interrupt requests (IRQ/FIQ).

**Figure 25-8. GIO Interrupt Enable Set Register (GIOENASET) [address = FFF7 BC10h]**

|             |    |             |    |

### 25.5.5 GIO Interrupt Priority Registers (GIOLVLSET and GIOLVLCLR)

The GIOLVLSET and GIOLVLCLR registers configure the interrupts as high-level (level 1) or low-level (level 2) going to the VIM. Each interrupt is individually configured.

- The high-level interrupts are recorded to GIOFF1 and GIOEMU1.
- The low-level interrupts are recorded to GIOFF2 and GIOEMU2.

#### 25.5.5.1 GIOLVLSET Register

The GIOLVLSET register is used to configure an interrupt as a high-level interrupt going to the VIM. An interrupt can be configured as a high-level interrupt by writing a 1 into the corresponding bit of the GIOLVLSET register. Writing a 0 has no effect. [Figure 25-10](#) and [Table 25-7](#) describe this register.

**Figure 25-10. GIO Interrupt Priority Register (GIOLVLSET) [address = FFF7 BC18h]**

|    |             |  |  |  |   |   |             |  |    |

### 25.5.5.2 GIOLVLCLR Register

The GIOLVLCLR register is used to configure an interrupt as a low-level interrupt going to the VIM. An interrupt can be configured as a low-level interrupt by writing a 1 into the corresponding bit of the GIOLVLCLR register. Writing a 0 has no effect. [Figure 25-11](#) and [Table 25-8](#) describe this register.

**Figure 25-11. GIO Interrupt Priority Register (GIOLVLCLR) [address = FFF7 BC1Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 25-8. GIO Interrupt Priority Register (GIOLVLCLR) Field Descriptions**

| Bit   | Field       | Value | Description                                                                                                                                                                                                                             |

## 25.5.6 GIO Interrupt Flag Register (GIOFLG)

The GIOFLG register contains flags indicating that the transition edge (as set in GIOINTDET and GIOPOL) has occurred. The flag is also cleared by reading the appropriate interrupt offset register (GIOOFF1 or GIOOFF2). [Figure 25-12](#) and [Table 25-9](#) describe this register.

**Figure 25-12. GIO Interrupt Flag Register (GIOFLG) [address = FFF7 BC20h]**

| R/WC-0   |    | R/WC-0   |    |

LEGEND: R/W = Read/Write; R = Read only; C = Clear; -n = value after reset

**Table 25-9. GIO Interrupt Flag Register (GIOFLG) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                           |
|-------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | GIOFLG 3 | 0     | GIO flag for pins GIOD[7:0]<br>Read: A transition has not occurred since the last clear.<br>Write: Writing a 0 to this bit has no effect.                                                                                             |
|       |          | 1     | Read: The selected transition on the corresponding pin has occurred.<br>Write: The corresponding bit is cleared to 0.<br><b>Note: This bit is also cleared by a read to the corresponding bit in the appropriate offset register.</b> |
| 23-16 | GIOFLG 2 | 0     | GIO flag for pins GIOC[7:0]<br>Read: A transition has not occurred since the last clear.<br>Write: Writing a 0 to this bit has no effect.                                                                                             |
|       |          | 1     | Read: The selected transition on the corresponding pin has occurred.<br>Write: The corresponding bit is cleared to 0.<br><b>Note: This bit is also cleared by a read to the corresponding bit in the appropriate offset register.</b> |
| 15-8  | GIOFLG 1 | 0     | GIO flag for pins GIOB[7:0]<br>Read: A transition has not occurred since the last clear.<br>Write: Writing a 0 to this bit has no effect.                                                                                             |
|       |          | 1     | Read: The selected transition on the corresponding pin has occurred.<br>Write: The corresponding bit is cleared to 0.<br><b>Note: This bit is also cleared by a read to the corresponding bit in the appropriate offset register.</b> |
| 7-0   | GIOFLG 0 | 0     | GIO flag for pins GIOA[7:0]<br>Read: A transition has not occurred since the last clear.<br>Write: Writing a 0 to this bit has no effect.                                                                                             |
|       |          | 1     | Read: The selected transition on the corresponding pin has occurred.<br>Write: The corresponding bit is cleared to 0.<br><b>Note: This bit is also cleared by a read to the corresponding bit in the appropriate offset register.</b> |

**NOTE:** An interrupt flag gets set when the selected transition happens on the corresponding GIO pin **regardless of whether the interrupt generation is enabled or not**. It is recommended to clear a flag before enabling the interrupt generation for a transition on the corresponding GIO pin.

### 25.5.7 GIO Offset Register 1 (GIOOFF1)

The GIOOFF1 register provides a numerical offset value that represents the pending external interrupt with high priority. The offset value can be used to locate the position of the interrupt routine in a vector table in application software. [Figure 25-13](#) and [Table 25-10](#) describe this register.

**NOTE:** Reading this register clears it, GIOEMU1 and the corresponding flag bit in the GIOFLG register. However, in emulation mode, a read to this register does not clear any register or flag. If more than one GIO interrupts are pending, then reading the GIOOFF1 register will change the contents of GIOOFF1 and GIOEMU1 to show the offset value for the next highest priority pending interrupt. The application can choose to service all GIO interrupts from the same service routine by continuing to read the GIOOFF1 register until it reads zeros.

**Figure 25-13. GIO Offset 1 Register (GIOOFF1) [address = FFF7 BC24h]**

LEGEND: R = Read only; -n = value after reset

**Table 25-10. GIO Offset 1 Register (GIOOFF1) Field Descriptions**

| Bit  | Field    | Value   | Description                                                                                                                                                                                                  |
|------|----------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-6 | Reserved | 0       | Read returns 0. Writes have no effect.                                                                                                                                                                       |
| 5-0  | GIOOFF1  |         | GIO offset 1. These bits index the currently pending high-priority interrupt. This register and the flag bit (in the GIOFLG register) are also cleared when this register is read, except in emulation mode. |
|      |          | 0       | No interrupt is pending.                                                                                                                                                                                     |

### 25.5.8 GIO Offset B Register (GIOFF2)

The GIOFF2 register provides a numerical offset value that represents the pending external interrupt with low priority. The offset value can be used to locate the position of the interrupt routine in a vector table in application software. [Figure 25-14](#) and [Table 25-11](#) describe this register.

**NOTE:** Reading this register clears it, GIOEMU2 and the corresponding flag bit in the GIOFLG register. However, in emulation mode, a read to this register does not clear any register or flag. If more than one GIO interrupts are pending, then reading the GIOFF1 register will change the contents of GIOFF2 and GIOEMU2 to show the offset value for the next highest priority pending interrupt. The application can choose to service all GIO interrupts from the same service routine by continuing to read the GIOFF1 register until it reads zeros.

**Figure 25-14. GIO Offset 2 Register (GIOFF2) [address = FFF7 BC28h]**

LEGEND: R = Read only; -n = value after reset

**Table 25-11. GIO Offset 2 Register (GIOFF2) Field Descriptions**

| Bit  | Field    | Value                                                                                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### 25.5.9 GIO Emulation A Register (GIOEMU1)

The GIOEMU1 register is a read-only register. The contents of this register are identical to the contents of GIOOFF1. The intention for the this register is that software can use it without clearing the flags. [Figure 25-15](#) and [Table 25-12](#) describe this register.

**NOTE:** The corresponding flag in the GIOFLG register is not cleared when the GIOEMU1 register is read.

**Figure 25-15. GIO Emulation 1 Register (GIOEMU1) [address = FFF7 BC2Ch]**

LEGEND: R = Read only; -n = value after reset

**Table 25-12. GIO Emulation 1 Register (GIOEMU1) Field Descriptions**

| Bit  | Field    | Value   | Description                                                                                                                                      |
|------|----------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-6 | Reserved | 0       | Read returns 0. Writes have no effect.                                                                                                           |
| 5-0  | GIOEMU1  | 0       | GIO offset emulation 1. These bits index the currently pending high-priority interrupt. No register or flag is cleared by reading this register. |
|      |          | 0       | No interrupt is pending.                                                                                                                         |

### 25.5.11 GIO Data Direction Registers [A-H][7:0] (GIODIR[A-H][7:0])

The GIODIR register controls whether the pins of a given port are configured as inputs or outputs. Figure 25-17 and Table 25-14 describe this register.

**Figure 25-17. GIO Data Direction Registers [A-H][7:0] (GIODIR[A-H])** [address = FFF7BC34h, FFF7BC54h, FFF7BC74h, FFF7BC94h, FFF7BCB4h, FFF7BCD4h, FFF7BCF4h, FFF7BD14h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 25-14. GIO Data Direction Registers [A-H][7:0] (GIODIR[A-H][7:0]) Field Descriptions**

| Bit  | Field     | Value | Description                                                                                                                                          |
|------|-----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved  | 0     | Read returns 0. Writes have no effect.                                                                                                               |
| 7-0  | GIODIR[X] | 0     | GIO data direction of port X, pins [7:0]<br>The GIO pin is an input. Note: If the pin direction is set as an input , the output buffer is tristated. |
|      |           | 1     | The GIO pin is an output.                                                                                                                            |

### 25.5.12 GIO Data Input Registers [A-H][7:0] (GIODIN[A-H][7:0])

Values in the GIODIN register reflect the current state (high = 1 or low = 0) on the pins of the port. Figure 25-18 and Table 25-15 describe this register.

**Figure 25-18. GIO Data Input Registers [A-H][7:0] (GIODIN[A-H])** [address = FFF7BC38h, FFF7BC58h, FFF7BC78h, FFF7BC98h, FFF7BCB8h, FFF7BCD8h, FFF7BCF8h, FFF7BD18h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 25-15. GIO Data Input Registers [A-H][7:0] (GIODIN[A-H][7:0]) Field Descriptions**

| Bit  | Field     | Value | Description                                                           |
|------|-----------|-------|-----------------------------------------------------------------------|
| 31-8 | Reserved  | 0     | Read returns 0. Writes have no effect.                                |
| 7-0  | GIODIN[X] | 0     | GIO data input for port X, pins [7:0]<br>The pin is at logic low (0). |
|      |           | 1     | The pin is at logic high (1).                                         |

### 25.5.13 GIO Data Output Registers [A-H][7:0] (GIODOUT[A-H][7:0])

Values in the GIODOUT register specify the output state (high = 1 or low = 0) of the pins of the port when they are configured as outputs. [Figure 25-19](#) and [Table 25-16](#) describe this register.

**NOTE:** Values in the GIODSET register set the data output control register bits to 1 regardless of the current value in the GIODOUT bits.

**Figure 25-19. GIO Data Output Registers [A-H][7:0] (GIODOUT[A-H][7:0]) [address = FFF7BC3Ch, FFF7BC5Ch, FFF7BC7Ch, FFF7BC9Ch, FFF7BCBCh, FFF7BCDCh, FFF7BCFCh, FFF7BD1Ch]**

## 26.1 Overview

The FlexRay module performs communication according to the FlexRay protocol specification v2.1 Rev. A. The sample clock bit rate can be programmed to values up to 10 Mbit/s. Additional bus driver (BD) hardware is required for connection to the physical layer.

For communication on a FlexRay network, individual message buffers with up to 254 data bytes are configurable. The message storage consists of a single-ported message RAM that holds up to 128 message buffers. All functions concerning the handling of messages are implemented in the message handler. Those functions are the acceptance filtering, the transfer of messages between the two FlexRay Channel Protocol Controllers and the message RAM, maintaining the transmission schedule as well as providing message status information.

The register set of the FlexRay module can be accessed directly by the CPU via the VBUS interface. These registers are used to control, configure and monitor the FlexRay channel protocol controllers, message handler, global time unit, system universal control, frame and symbol processing, network management, interrupt control, and to access the message RAM via the input / output buffer.

### 26.1.1 Feature List

- Conformance with FlexRay protocol specification v2.1 Rev. A
- Data rates of up to 10 Mbit/s on each channel
- Up to 128 message buffers
- 8 Kbyte of message RAM for storage of, for example, 128 message buffers with maximum of 48-byte data section or up to 30 message buffers with 254-byte data section
- Configuration of message buffers with different payload lengths
- One configurable receive FIFO
- Each message buffer can be configured as receive buffer, as transmit buffer or as part of the receive FIFO
- CPU access to message buffers via input and output buffer
- Specialized DMA like FlexRay Transfer Unit (FTU) for automatic data transfer between data memory and message buffers without CPU interaction
- Filtering for slot counter, cycle counter, and channel
- Maskable module interrupts
- Supports Network Management

## 26.2 FlexRay Module Block Diagram

Figure 26-1. Block Diagram

The TI FlexRay module contains the following blocks:

- Peripheral Interface (VBUS IF)

Interface to the Peripheral Bus of the TMS570 microcontroller architecture. The FlexRay module can either act as a VBUS master or VBUS slave.

- FlexRay Transfer Unit (FTU)

The internal intelligent state-machine (Transfer Unit State Machine) is able to transfer data between the input buffer (IBF) and output buffer (OBF) of the communication controller and the system memory without CPU interaction.

---

**NOTE:** Since the FlexRay module is accessed through the FTU, the FTU must be powered up by the corresponding bit in the Peripheral Power Down Registers of the System Module before accessing any FlexRay module register. For details please refer to the Architecture Documentation and the device specific data sheet.

---

- Input Buffer (IBF)

For write access to the message buffers configured in the message RAM, the CPU or the FTU can write the header and data section for a specific message buffer to the input buffer. The message handler then transfers the data from the input buffer to the selected message buffer in the message RAM.

- **Output Buffer (OBF)**  
For read access to a message buffer configured in the message RAM the message handler transfers the selected message buffer to the output buffer. After the transfer has completed, the CPU or the FTU can read the header and data section of the transferred message buffer from the output buffer.
- **Message Handler (MHD)**  
The message handler controls data transfers between the following components:
  - Input / output buffer and message RAM
  - Transient buffer RAMs of the two FlexRay protocol controllers and message RAM
- **Message RAM**  
The message RAM stores up to 128 FlexRay message buffers together with the related configuration data (header and data partition).
- **The Transient Buffer RAM (TBF A/B):**  
Stores the data section of two complete messages.
- **FlexRay Channel Protocol Controller (PRT A/B)**  
The FlexRay channel protocol controllers consist of a shift register and the FlexRay protocol FSM (Finite State Machine). They are connected to the transient buffer RAMs for intermediate message storage and to the physical layer via bus drivers (BD).  
They perform the following functionality:
  - Control and check of bit timing
  - Reception / transmission of FlexRay frames and symbols
  - Check of header CRC
  - Generation / check of frame CRC
  - Interfacing to bus driver
 The FlexRay channel protocol controllers have interfaces to:
  - Physical layer (bus driver)
  - Transient buffer RAM
  - Message handler
  - Global Time Unit
  - System universal control
  - Frame and symbol processing
  - Network management
  - Interrupt control
- **Global time unit (GTU)**  
The GTU performs the following functions:
  - Generation of microtick
  - Generation of macrotick
  - Fault tolerant clock synchronization by FTM algorithm
    - rate and offset correction
    - offset correction
  - Cycle counter
  - Timing control of static segment
  - Timing control of dynamic segment (minislotting)
  - Support of external clock correction

- System Universal Control (SUC)  
The SUC controls the following functions:
  - Configuration
  - Wakeup
  - Startup
  - Normal Operation
  - Passive Operation
  - Monitor Mode
- Frame and Symbol Processing (FSP)  
The frame and symbol processing controls the following functions:
  - Checks the correct timing of frames and symbols
  - Tests the syntactical and semantic correctness of received frames
  - Sets the slot status flags
- Network Management (NEM)  
Handles the network management vector.
- Interrupt Control (INT)  
The interrupt controller performs the following functions:
  - Provides error and status interrupt flags
  - Enable / disable interrupt sources
  - Assignment of interrupt sources to the two module interrupt lines
  - Enable / disable module interrupt lines
  - Manages the two interrupt timers
  - Stop watch time capturing
- 80MHz Clock Signal  
Clock signal for the sample clock (SCLK) of the FlexRay module.

---

**NOTE:** AVCLK2 is used to provide the 80MHz clock to the FlexRay Module. The second PLL / Clock Source 6 in the microcontroller is typically used as source for AVCLK2.

---

- Module Clock (VBUS<sub>CLK</sub>)  
The FlexRay module clock (BCLK) is derived from the Peripheral Clock VBUS<sub>CLK</sub> of the microcontroller.

## 26.3 FlexRay Module Block Mapping

The following [Figure 26-2](#) shows the different module blocks of the FlexRay module. It is split into 3 sections, the communication controller, the transfer unit and the transfer unit RAM. The RAM of the communication controller is only memory mapped in test mode, where it is mapped to the register set address range.

**Figure 26-2. FlexRay Module Blocks**

The address ranges of the 3 FlexRay blocks are shown in [Table 26-1](#).

**Table 26-1. FlexRay Address Range Table**

| Module                           | Address Range               |
|----------------------------------|-----------------------------|
| FlexRay Communication Controller | 0xFFFF7_C800 - 0xFFFF7_CFFF |
| FlexRay TU                       | 0xFFFF7_A000 - 0xFFFF7_A1FF |
| FlexRay TU RAM                   | 0xFF50_0000 - 0xFF51_FFFF   |

## 26.4 Transfer Unit Block Diagram

Figure 26-3. Transfer Unit

The FlexRay Transfer Unit (FTU) has an internal intelligent state-machine (Transfer Unit State Machine) to transfer data between the Input and Output Buffer Interfaces of the FlexRay core module and the system memory of the microcontroller without CPU interaction. It operates in a similar manner to a DMA (Direct Memory Access) module.

The FlexRay Input Buffer (IBF) and FlexRay Output Buffer (OBF) can also be accessed directly by the CPU. In this case the IBF and OBF are 8-, 16-, and 32-bit accessible. For transfers using the Transfer Unit State Machine only 4x32-bit data packages (4 word bursts) are supported.

The Interface Arbiter controls the access to the IBF and OBF. Direct CPU accesses to IBF and OBF are not possible, if the Transfer Unit State Machine is switched on. Accesses will be ignored and the associated error interrupt will be generated.

The Transfer Unit State Machine is the head of all manual, event driven and automatic message transfer activities. It controls the Transfer Unit interrupt generation related to transfer protocol correctness, status and violations of the message transfers.

With the Transfer Configuration RAM (TCR) the transfer sequence, executed by the Transfer Unit State Machine, can be configured.

The usage of the Transfer Unit allows the user to setup a mirror of the FlexRay message RAM in the fast accessible data RAM of the microcontroller. The Transfer Unit can handle the data transfers between the data RAM and the FlexRay message RAM in the 'background' without CPU interaction.

## 26.5 Transfer Unit Functional Description

Figure 26-4 shows the principle of the Transfer Unit operation.

**Figure 26-4. FlexRay Transfer Unit Operation Principle**

Each FlexRay message buffer of the FlexRay message buffer RAM has one Transfer Configuration RAM (TCR) entry assigned to it, i.e. message buffer 1 is assigned to TCR1, message buffer 2 is assigned to TCR2 and so forth.

The Transfer Base Address (TBA) register of the Transfer Unit holds the message buffer base address in the data RAM. Each Transfer Configuration RAM (TCR) entry contains a 14 bit offset value to the dedicated message buffer area in the data RAM.

The following two diagrams show the principle of the Transfer Unit operation including Transfer State Machine (see Figure 26-5) and Event State Machine (see Figure 26-6).

**Figure 26-5. FlexRay Transfer Unit Operation Principle for Transfer FSM (simplified)**

**Figure 26-6. FlexRay Transfer Unit Operation Principle for Event FSM (simplified)**

| ETESMS/R | CESMS/R | Set bit TTSM | Clear bit ETESMS/R |
|----------|---------|--------------|--------------------|
| 0        | -       | False        | False              |
| 1        | 0       | True         | False              |
| 1        | 1       | True         | True               |

## 26.5.1 Transfer Control

### 26.5.1.1 Transfer Start and Halt

The Transfer Unit State Machine can be halted, effectively stopping the Transfer Unit transfer sequence (after completion of the current 4 word burst transfer cycle). After releasing from halt state, the Transfer Unit resumes exactly, where it was halted without data loss.

**NOTE:** It is the software's responsibility to ensure data coherency when the FlexRay module continues to receive data, but the Transfer Unit doesn't transfer it.

### 26.5.1.2 Transfer Abort

A Transfer Unit transfer will be aborted and the Transfer Unit will be disabled automatically in case of:

- a parity error while accessing the Transfer Configuration RAM (TCR)
- a memory protection error while accessing the data RAM of the microcontroller. In this case, the ongoing transfer is aborted but the TUE bit in GCS/R may not get reset. User shall clear the TUE bit manually by software.

### 26.5.1.3 Transfer Reset

The Transfer Unit State Machine can be reset by the Transfer Unit Enable (TUE) bit in the Global Control register. Though the Transfer Unit State Machine can be reset with the above, the module register contents and the Transfer Configuration RAM (TCR). So, after re-enabling the Transfer Unit no reconfiguration of the Transfer Unit is required.

### 26.5.1.4 Transfer Modes

Possible transfer sequence modes are:

- Manual by triggering the desired transfer by setting the corresponding bit in the Trigger Transfer to System Memory (TTSM) register or the Trigger Transfer to Communication Controller (TTCC) register
- Event-Driven (transfers from FlexRay Communication Controller to the System Memory only) using the Enable Transfer on Event to System Memory (ETESM) register.
- Single or continuous event driven transfers by using the Clear on Event to System Memory (CESM)

The transfer event trigger in general occurs upon completion of a reception or transmission of a frame through the FlexRay bus. [Table 26-2](#) shows more details: Conditions marked with 'X' per row must match to trigger a FTU transfer event as configured in the Transfer Configuration RAM (TCR):

**Table 26-2. FlexRay Transfer Unit Event Trigger Conditions**

|                                                | Event on Channel A | Event on Channel B | Frame belonging to static segment or first slot of dynamic segment | Frame belonging to dynamic segment, except first slot of dynamic segment | Bus activity detected on Channel A (MBS.ESA = 0) | Bus activity detected on Channel B (MBS.ESB = 0) |
|------------------------------------------------|--------------------|--------------------|--------------------------------------------------------------------|--------------------------------------------------------------------------|--------------------------------------------------|--------------------------------------------------|
| FTU Event Trigger for Receive Message Buffers  | X                  |                    | X                                                                  |                                                                          |                                                  |                                                  |
|                                                |                    | X                  | X                                                                  |                                                                          |                                                  |                                                  |
|                                                | X                  |                    |                                                                    | X                                                                        | X                                                |                                                  |
|                                                |                    | X                  |                                                                    | X                                                                        |                                                  | X                                                |
| FTU Event Trigger for Transmit Message Buffers | X                  |                    |                                                                    |                                                                          | X                                                |                                                  |
|                                                |                    | X                  |                                                                    |                                                                          |                                                  | X                                                |

**NOTE:** By setting the corresponding bit in the Enable Transfer on Event to System Memory (ETESM) register prior to a on-demand transfer to the Communication Controller via the Trigger Transfer to Communication Controller (TTCC) register, an event triggered transmission back to the System Memory can be initiated, once the buffer has been sent out on the FlexRay bus. This mechanism can be used i.e. to automatically read back the header status information to the system memory after a transmission occurred.

**NOTE:** The transmission or reception of null frames in the static segment of a FlexRay communication cycle triggers transfers of the transfer unit. The header and/or payload is transferred to the system memory, if the corresponding bits THTSM and/or TPTSM in the Transfer Configuration RAM (TCR) are set. If neither THTSM nor TPTSM bit is set in TCR, neither header nor payload gets transferred. The corresponding bit in the Transfer to System Memory Occurred register (TSMO) gets set in all cases.

### 26.5.1.5 Transfer Size and Types

The data transferred by the Transfer Unit can be selected as:

- data and header section
- header section only
- data section only

The number of transferred payload words is derived from the Payload Length Configured (PLC) information configured in the Write Header Section 2 (WRHS2) register.

As only 4 word bursts are supported for the Transfer Unit transfers, only multiple of 4x32-bit data packets are supported. Additional transferred words are undefined, as indicated in [Figure 26-7](#) and [Figure 26-8](#).

**Figure 26-7. Example: FTU Read Transfer of 6 Words**

**Figure 26-8. Example: FTU Write Transfer of 6 Words**

Physically the FTU continues reading the additional words from the source location it started the burst transfer. Therefore, on reads, the additional transferred words depend on the contents of the Communication Controller Output Buffer Registers as indicated in [Figure 26-7](#). On writes the additional words depend on the contents of the data RAM, as shown in [Figure 26-8](#). The additional data will be written to the Communication Controller's Input Buffer Registers, but not transferred to the message RAM.

**NOTE:** It should be ensured that the allocated data RAM space for FTU transfers ends on 4x32 bit boundary to avoid possible data overwrites or memory protection issues on FTU reads and avoid reading the additional data from the source location on FTU writes.

#### 26.5.1.6 Transfer Status Indication

There are 3 registers indicating the transfer status:

- Transfer Status Current Buffer (TSCB) shows the current transfer buffer status
- Last Transferred Buffer to Communication Controller (LTBCC) indicates the last completed buffer transfer to the communication controller
- Last Transferred Buffer to System Memory (LTBSM) shows the last completed buffer transfer to system memory

### 26.5.1.7 Transfer Mirror Function

In order to efficiently access the transfer unit status registers in the system memory, the following registers can be mirrored to the system memory starting at the base address defined in the Base Address of Mirrored Status (BAMS) register:

- Transfer Status Current Buffer (TSCB)
- Last Transferred Buffer to Communication Controller (LTBCC)
- Last Transferred Buffer to System Memory (LTBSM)
- Transfer to System Memory Occurred 1/2/3/4 (TSMO1-4)
- Transfer to Communication Controller Occurred 1/2/3/4 (TCCO1-4)
- Transfer Occurred OFFset (TOOFF)

The mirrored values are updated after completion of a buffer transfer.

The mirroring of these registers can be disabled if not needed.

**Table 26-3. Mirroring Address Mapping**

| Address   | Register |
|-----------|----------|
| BAMS+0x00 | TSCB     |
| BAMS+0x04 | LTBCC    |
| BAMS+0x08 | LTBSM    |
| BAMS+0x0C | TSMO1    |
| BAMS+0x10 | TSMO2    |
| BAMS+0x14 | TSMO3    |
| BAMS+0x18 | TSMO4    |
| BAMS+0x1C | TCCO1    |
| BAMS+0x20 | TCCO2    |
| BAMS+0x24 | TCCO3    |
| BAMS+0x28 | TCCO4    |
| BAMS+0x2C | TOOFF    |

### 26.5.1.8 Endianness Correction

For the data transfer by the Transfer Unit an Endianness correction mechanism can be used to switch big Endianness data to little Endianness data and vice versa.

For maximum flexibility, 6 bits are available in the Global Control Set/Reset Register (GCS/R) to control.

- Header Data byte-order
- Payload Data byte-order
- Byte-order of the FlexRay Core registers and the Transfer Configuration RAM data of the Transfer Unit independently and in both directions.

### 26.5.1.9 Transfer Data Package

Table 26-4 shows the data of a transfer data package. Independent of whether the header gets transferred or not, the buffer address always points to element Header1.

**Table 26-4. Mirroring Address Mapping**

| Address | Register                     |
|---------|------------------------------|
| 0x0000  | Header1                      |
| 0x0004  | Header2                      |
| 0x0008  | Header3                      |
| 0x000C  | Buffer Status <sup>(1)</sup> |
| 0x0010  | Payload1                     |
| 0x0014  | Payload2                     |
| ....    | ....                         |
| 0x010C  | Payload64                    |

<sup>(1)</sup> Transferred only from Communication Controller to System Memory

### 26.5.1.10 Transfer Start Address to Message Buffer Number Assignment

The assignment of a FlexRay message buffer number to the transfer location in system memory is done by the combination of

- the Transfer Start Offset (TSO) field in a Transfer Configuration RAM (TCR) entry
- the Transfer Base Address (TBA) register

Each entry of the TCR holds a 14 bit offset value (TSO). The TSO offset will be added to the content of the TBA register. The TBA register holds the 32bit base address-pointer to a location of the data RAM.

A value written to Next Transfer Base Address (NTBA) will be loaded in the TBA at the next communication cycle start. This allows efficient multi-buffering of the message buffers in the system memory. The Transfer Not Ready (NTR) flag in the Transfer Error Interrupt Flag (TEIF) register can be used to determine, if NTBA can be reloaded by the CPU.

**NOTE:** If a value is written to TBA, NTBA is set to the same value.

**Figure 26-9. Transfer Start Address to Message Buffer Number Assignment**

### 26.5.1.11 Transfer Priority

The Transfer Unit will transfer the message buffers from low to high message buffer numbers.

In case the same buffer is pending in both the Trigger Transfer to Communication (TTCC) register and the Trigger Transfer to System Memory (TTSM) register, the priority between TTCC and TTSM is determined by the Transfer Priority bit (GC.PRIO) in the Transfer Unit Global Control Set/Reset Register (GCS/R).

#### 26.5.1.12 Read Transfers

A read transfer is the data transfer from FlexRay message buffer RAM to the system memory of the microcontroller.

For read transfers the registers Trigger Transfer to System Memory (TTSM), Enable Transfer on Event to System Memory (ETESM) and Clear on Event to System Memory (CESM) have to be setup.

The amount and type of data to be transferred can be selected as:

- data and header section
- header section only
- data section only

which can be configured on the Transmit Configuration RAM (TCR).

The number of 32 bit words per buffer to be transferred is read from the Payload Length Configured (RDHS2.PLC[6:0]) configuration information. This information is part of the header section stored in the message RAM of the Communication Controller.

#### 26.5.1.13 Write Transfers

A write transfer is the data transfer from the system memory of the microcontroller to the FlexRay message buffer RAM.

For write transfers the Trigger Transfer to Communication (TTCC) register has to be setup.

The amount and type of data transferred can be selected as:

- data and header section
- header section only
- data section only

which can be configured on the Transmit Configuration RAM (TCR).

It can be configured in the TCR, if Set Transmission Request Host (STXRH) bit in the Input Buffer Command Mask (IBCM) of the Communication Controller should be set. This would trigger the transfer to the FlexRay bus.

If a data and header section transfer is selected, the number of 32 bit words to be transferred is read from the Payload Length Configured (PLC) configuration information stored in Header2 word in the system memory.

If a data section only transfer is selected, the number of 32 bit words to be transferred is read from the Payload Length Configured (RDHS2.PLC[6:0]) configuration information. This information is part of the header section stored in the message RAM of the Communication Controller.

#### 26.5.1.14 Transfer Unit Event Interface

The Transfer Unit Event Control generates transfer trigger signals for transfers in the following cases:

- For transmit (TX) message buffers, a write transfer trigger is generated, if a transmit event occurs. The configured TX message buffers generate a transfer trigger, except when a Nullframe in static segment or no frame in the dynamic segment is sent.
- For receive (RX) message buffers, a read transfer trigger is generated, if a receive event occurs in the static segment.
- For receive (RX) message buffers, a read transfer trigger is generated if a receive event occurs in the dynamic segment, updated in the current cycle and no Nullframe.

If a buffer is part of the FIFO, no transfer trigger is generated!

When the Transfer Unit is disabled (TUE bit in Global Control Register (GCS/R) is '0'), no transfer trigger is generated, whereas if the Transfer Unit is enabled, but in halt mode (TUH bit and TUE bit in Global Control Register (GCS/R) are '1'), the occurring triggers remain pending and get executed when the Transfer Unit will be resumed from halt mode.

## 26.5.2 Transfer Configuration RAM

The Transfer Configuration RAM (TCR) consists of 128 entries, one entry for each possible FlexRay buffer. Entry 1 is assigned to FlexRay buffer 1, entry 2 to FlexRay buffer 2,..., and entry 128 is assigned to FlexRay buffer 128.

Each TCR entry defines:

- data transfer size (header + data, header only or data only)
- whether the transmit request flag (STRXH) should be set for the data transferred by the FTU to the CC to send out the data to the FlexRay bus.
- the 14-bit buffer address offset, which, in combination with the Transfer Base Address defined in TBA, specifies the start of the corresponding FlexRay message buffer in the system memory RAM.

---

**NOTE:** It is recommended to clear the whole TCR before configuring it, in order to avoid unexpected transfer behavior due to old configuration contents or random TCR RAM contents after power on reset.

---

---

**NOTE:** If a transfer is triggered but no transfer size (header or data) is setup in the TCR, no data will be transferred, but the corresponding flag in the Transfer to Communication Controller Occurred (TCCOx) or the Transfer to System Memory Occurred (TSMOx) will be set.

---

### 26.5.2.1 Parity Protection

The Transfer Configuration RAM (TCR) is parity protected. The parity error interrupt generation is disabled by default and can be switched on by writing a 4 bit key to dedicated parity lock bits in the Global Control Set/Reset Register (GCS/R).

The parity protection supports even and odd parity. The parity information is stored together with the corresponding 19 bit data word entry.

The parity is checked each time a data word is read from the TCR RAM. If a parity error is detected, the PE error flag is set in the Transfer Error Interrupt Flag (TEIF) register.

Additionally an uncorrectable RAM error interrupt/event will be generated. The uncorrectable RAM error interrupt/event is non maskable and therefore cannot be switched off. The uncorrectable RAM error is hooked up to the ESM module (event).

For parity errors the faulty TCR RAM address can be read from the Parity Error Address (PEADR) register.

## 26.5.3 Memory Protection Mechanism

This feature allows to restrict accesses to certain areas in memory in order to protect critical application data from unintentionally being accessed by the Transfer Unit State Machine.

One memory section (start- and end address) can be defined, which allows read and write accesses for the Transfer Unit State Machine.

If the end address is smaller or equal to the start address, data transfers will be blocked. Any accesses performed outside this memory area by the Transfer Unit State Machine result in no transfers being performed. In case of a protection violation a flag will be set and the Memory Protection Violation interrupt will be activated. The Transfer Unit State Machine will be disabled in this case.

The default setting of the Transfer Unit State Machine memory protection address range setup is:

- 0x00000000 for start address
- 0x00000000 for end address

This means a valid address range must be setup, before the Transfer Unit can be used.

## 26.6 Communication Cycle

**Figure 26-10. Structure of Communication Cycle**

A communication cycle in FlexRay consists of the following elements:

- Static segment
- Dynamic segment
- Symbol window
- Network idle time (NIT)

Static segment, dynamic segment, and symbol window form the network communication time (NCT). For each communication channel the slot counter starts at 1 and counts up until the end of the dynamic segment is reached. Both channels share the same arbitration grid which means that they use the same synchronized macrotick.

### 26.6.1 Static Segment

The Static Segment is characterized by the following features:

- Time slots of fixed length (optionally protected by bus guardian)
- Start of frame transmission at action point of the corresponding static slot
- Payload length same for all frames on both channels

**Parameters:** number of static slots GTUC7.NSS(9-0), static slot length GTUC7.SSL(9-0), Payload Length Static MHDC.SFDL(6-0), action point offset GTUC9.APO(5-0)

### 26.6.2 Dynamic Segment

The Dynamic Segment is characterized by the following features:

- All controllers have bus access (no bus guardian protection possible)
- Variable payload length and duration of slots, different for both channels
- Start of transmission at minislot action point

**Parameters:** number of minislots GTUC8.NMS(12-0), minislot length GTUC8.MSL(5-0), minislot action point offset GTUC9.MAPO(4-0), start of latest transmit (last minislot) MHDC.SLT(12-0)

### 26.6.3 Symbol Window

During the symbol window only one media access test symbol (MTS) may be transmitted per channel. MTS symbols are sent in NORMAL\_ACTIVE state to test the bus guardian.

The symbol window is characterized by the following features:

- Send single symbol
- Transmission of the MTS symbol starts at the symbol windows action point

**Parameters:** Symbol Window Action Point Offset GTUC9.APO(4-0) (same as for static slots), Network Idle Time Start GTUC4.NIT(13-0)

### 26.6.4 Network Idle Time (NIT)

During network idle time the communication controller has to perform the following tasks:

- Calculate clock correction terms (offset and rate)
- Distribute offset correction over multiple macroticks after offset correction start
- Perform cluster cycle related tasks

**Parameters:** network idle time start GTUC4.NIT(13-0), offset correction start GTUC4.OCS(13-0)

### 26.6.5 Configuration of NIT Start and Offset Correction Start

**Figure 26-11. Configuration of NIT Start and Offset Correction Start**

The number of macroticks per cycle is assumed to be  $m$ . It is configured by programming GTUC2.MPC =  $m$  in the GTU Configuration register 2.

The static / dynamic segment starts with macrotick 0 and ends with macrotick  $n$ :  $n$  = static segment length + dynamic segment offset + dynamic segment length - 1MT

The static segment length is configured by GTUC7.SSL and GTUC7.NSS. The dynamic segment length is configured by GTUC8.MSL and GTUC8.NMS.

The dynamic segment offset is ActionPointOffset - MinislotActionPointOffset or 0 MT if the result is negative. For details please refer to the FlexRay Communications System Protocol Specification from the FlexRay Consortium.

The NIT starts with macrotick  $k+1$  and ends with the last macrotick of cycle  $m-1$ . It has to be configured by setting GTUC4.NIT =  $k$ .

For this FlexRay module the offset correction start is required to be GTUC4.OCS  $\geq$  GTUC4.NIT + 1 =  $k+1$ .

The length of symbol window results from the number of macroticks between the end of the static / dynamic segment and the beginning of the NIT. It can be calculated by  $k - n$ .

## 26.7 Communication Modes

The FlexRay protocol specification v2.1 Rev. A defines the Time-Triggered Distributed (TT-D) mode.

### 26.7.1 Time-Triggered Distributed (TT-D)

In TT-D mode the following configurations are possible:

- Pure static: minimum 2 static slots + symbol window (optional)
- Mixed static/dynamic: minimum 2 static slots + dynamic segment + symbol window (optional)

A minimum of two coldstart nodes need to be configured for distributed time-triggered operation. Two fault-free coldstart nodes are necessary for the cluster startup. Each startup frame must be a sync frame, therefore all coldstart nodes are sync nodes.

## 26.8 Clock Synchronization

In TT-D mode a distributed clock synchronization is used. Each node individually synchronizes itself to the cluster by observing the timing of received sync frames from other nodes.

### 26.8.1 Global Time

Activities in a FlexRay node, including communication, are based on the concept of a global time, even though each individual node maintains its own view of it. It is the clock synchronization mechanism that differentiates the FlexRay cluster from other node collections with independent clock mechanisms. The global time is a vector of two values; the cycle (cycle counter) and the cycle time (macrotick counter).

Cluster specific:

- Macrotime (MT) = basic unit of time measurement in a FlexRay network, a macrotime consists of an integer number of microtimes ( $\mu T$ )
- Cycle length = duration of a communication cycle in units of macrotimes (MT)

### 26.8.2 Local Time

Internally, nodes time their behavior with microtime resolution. Microtimes are time units derived from the oscillator clock tick of the specific node. Therefore microtimes are controller-specific units. They may have different duration in different controllers. The precision of a nodes local time difference measurements is a microtime ( $\mu T$ ).

Node specific:

- Sample clock  $\rightarrow$  prescaler  $\rightarrow$  microtime ( $\mu T$ ); typically 25ns.
- $\mu T$  = basic unit of time measurement in a communication controller, clock correction is done in units of  $\mu Ts$
- Cycle counter + macrotime counter = nodes local view of the global time

### 26.8.3 Synchronization Process

Clock synchronization is performed by means of sync frames. Only preconfigured nodes (sync nodes) are allowed to send sync frames. In a two-channel cluster, a sync node has to send its sync frame on both channels.

For synchronization in FlexRay the following constraints have to be considered:

- Max. one sync frame per node in one communication cycle
- Max. 15 sync frames per cluster in one communication cycle
- Every node has to use a preconfigured number of sync frames (GTUC2.SNM(3-0)) for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of sync frames received during the static segment is measured. In a two channel cluster the sync node has to be configured to send sync frames on both channels. The calculation of correction terms is done during NIT (offset: every cycle, rate: odd cycle) by using a FTA / FTM algorithm. For details see FlexRay protocol specification v2.1 Rev. A.

#### 26.8.3.1 Offset (Phase) Correction

- Only deviation values measured and stored in the current cycle used
- For a two channel node the smaller value will be taken
- Calculation during NIT of every communication cycle
- Offset correction value calculated in even cycles used for error checking only
- Checked against limit values
- Correction value is a signed integer number of  $\mu Ts$

- Correction done in odd numbered cycles, distributed over the macroticks beginning at offset correction start up to cycle end (end of NIT) to shift nodes next start of cycle (MTs lengthened / shortened)

### 26.8.3.2 Rate (Frequency) Correction

- Pairs of deviation values measured and stored in even / odd cycle pair used
- For a two channel node the average of the differences from the two channels is used
- Calculated during NIT of odd numbered cycles
- Cluster drift damping is performed using global damping value
- Checked against limit values
- Correction value is a signed integer number of  $\mu$ Ts
- Distributed over macroticks comprising the next even/odd cycle pair (MTs lengthened / shortened)

### 26.8.4 Sync Frame Transmission

Sync frame transmission is only possible from buffer 0 and 1. Message buffer 1 may be used for sync frame transmission in case that sync frames should have different payloads on the two channels. In this case bit MRC.SPLM has to be programmed to 1.

Message buffers used for sync frame transmission have to be configured with the key slot ID and can be (re)configured in DEFAULT\_CONFIG or CONFIG state only. For nodes transmitting sync frames SUCC1.TXSY must be set to 1.

### 26.8.5 External Clock Synchronization

During normal operation, independent clusters can drift significantly. If synchronous operation across independent clusters is desired, external synchronization is necessary; even though the nodes within each cluster are synchronized. This can be accomplished with synchronous application of host-deduced rate and offset correction terms to the clusters.

- External offset / rate correction value is a signed integer
- External offset / rate correction value is added to calculated offset / rate correction value
- Aggregated offset / rate correction term (external + internal) is not checked against configured limits

## 26.9 Error Handling

The implemented error handling concept of the FlexRay protocol is intended to ensure that in the presence of a lower layer protocol error in a single node, communication between non-affected nodes can be maintained. In some cases, higher layer program command activity is required for the communication controller to resume normal operation. A change of the error handling state will set bit EIR.PEMC and can trigger an interrupt to the host if enabled. The current error mode is signaled by CCEV.ERRM(1-0).

**Table 26-5. Error Modes of the POC (Degradation Model)**

| Error Mode | Activity                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACTIVE     | <b>Full operation</b> , State: NORMAL_ACTIVE<br>The communication controller is fully synchronized and supports the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status flags from registers EIR and SIR.                                                                                                                                                                                                   |

Clock synchronization mechanisms are continued based on received frames. No active contribution to the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status flags from registers EIR and SIR. |
| COMM_HALT  | <b>Operation halted</b> , State: HALT, communication controller self rescue not allowed<br>The communication controller stops frame and symbol processing, clock synchronization processing, and the macrotick generation. The host has still access to error and status information by reading the error and status flags from registers EIR and SIR. The bus drivers are disabled.                                                                                                                                     |

### 26.9.1 Clock Correction Failed Counter

When the Clock Correction Failed Counter reaches the “maximum without clock correction passive” limit defined by SUCC3.WCP(3-0), the POC transits from NORMAL\_ACTIVE to NORMAL\_PASSIVE state. When it reaches the “maximum without clock correction fatal” limit defined by SUCC3.WCF(3-0), it transits NORMAL\_ACTIVE or NORMAL\_PASSIVE to the HALT state.

The Clock Correction Failed Counter CCEV.CCFC(3-0) allows the host to monitor the duration of the inability of a node to compute clock correction terms after the communication controller passed protocol startup phase. It will be incremented by one at the end of any odd numbered communication cycle where either the Missing Offset Correction flag SFS.MOCS or the Missing Rate Correction flag SFS.MRCS is set.

The clock correction failed counter is reset to zero at the end of an odd communication cycle if neither the Missing Offset Correction flag SFS.MOCS nor the Missing Rate Correction flag SFS.MRCS is set.

The Clock Correction Failed Counter stops incrementing when the “maximum without clock correction fatal” value SUCC3.WCF(3-0) is reached (i.e. incrementing the counter at its maximum value will not cause it to wraparound back to zero). The clock correction failed counter will be initialized to zero when the communication controller enters READY state or when NORMAL\_ACTIVE state is entered.

---

**NOTE:** The transition to HALT state is prevented if SUCC1.HCSE is not set.

---

### 26.9.2 Passive to Active Counter

The passive to active counter controls the transition of the POC from NORMAL\_PASSIVE to NORMAL\_ACTIVE state. SUCC1.SUCC1.PTA(4-0) defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the communication controller is allowed to transit from NORMAL\_PASSIVE to NORMAL\_ACTIVE state. If SUCC1.PTA(4-0) is set to zero the communication controller is not allowed to transit from NORMAL\_PASSIVE to NORMAL\_ACTIVE state.

### 26.9.3 HALT Command

In case the host wants to stop FlexRay communication of the local node it can bring the communication controller into HALT state by asserting the HALT command. This can be done by writing SUCC1.CMD(3-0) = 0110. In order to shut down communication on an entire FlexRay network, a higher layer protocol is required to assure that all nodes apply the HALT command at the same time.

The POC state from which the transition to HALT state took place can be read from CCSV.PSL(5-0).

When called in NORMAL\_ACTIVE or NORMAL\_PASSIVE state the POC transits to HALT state at the end of the current cycle. When called in any other state SUCC1.CMD(3-0) will be reset to 0000 = “command\_not\_accepted” and bit EIR.CNA in the error interrupt register is set to 1. If enabled an interrupt to the host is generated.

### 26.9.4 FREEZE Command

In case the host detects a severe error condition it can bring the communication controller into HALT state by asserting the FREEZE command. This can be done by writing SUCC1.CMD(3-0) = 0111. The FREEZE command triggers the entry of the HALT state immediately regardless of the current POC state.

The POC state from which the transition to HALT state took place can be read from CCSV.PSL(5-0).

## 26.10 Communication Controller States

### 26.10.1 Communication Controller State Diagram

**Figure 26-12. Overall State Diagram of Communication Controller**

State transitions are controlled by the reset and FlexRay receive (rx1, 2) pins, the POC state machine, and by the CHI command vector SUCC1.CMD(3-0).

The Communication Controller exits from all states to HALT state after application of the FREEZE command (SUCC1.CMD(3-0) = 0111b).

**Table 26-6. State Transitions of Communication Controller Overall State Machine**

| T# | Condition                             | From           | To             |

| 17 | Command CONFIG, SUCC1.CMD(3-0) = 0001                                                                                                                                                  | HALT                                         | DEFAULT_CONFIG |

### 26.10.2 DEFAULT\_CONFIG State

In DEFAULT\_CONFIG state, the communication controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state.

The communication controller enters this state:

- When leaving hardware reset
- When exiting from HALT state

To leave DEFAULT\_CONFIG state the host has to write SUCC1.CMD(3-0) = 0001. The communication controller then transits to CONFIG state.

### 26.10.3 CONFIG State

In CONFIG state, the communication controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state. This state is used to initialize the communication controller configuration.

The communication controller enters this state:

- When exiting from DEFAULT\_CONFIG state
- When exiting from MONITOR\_MODE or READY state

When the state has been entered by HALT and DEFAULT\_CONFIG state, the host can analyze status information and configuration. Before leaving CONFIG state the host has to assure that the configuration is fault-free.

To leave CONFIG state, the host has to perform the unlock sequence. Directly after unlocking the CONFIG state the host has to write SUCC1.CMD(3-0) to enter the next state.

---

**NOTE:** The message buffer status registers (MHDS, TXRQ1/2/3/4, NDAT1/2/3/4, MBSC1/2/3/4) and status data stored in the message RAM and are not affected by the transition of the POC from CONFIG to READY state.

---

When the communication controller is in CONFIG state it is also possible to bring the communication controller into a power saving mode by halting the module clocks. To do this the host has to assure that all Message RAM transfers have finished before turning off the clocks.

#### 26.10.4 MONITOR\_MODE

After unlocking CONFIG state and writing SUCC1.CMD(3-0) = 1011 the communication controller enters MONITOR\_MODE. In this mode the communication controller is able to receive FlexRay frames and to detect wakeup pattern. The temporal integrity of received frames is not checked, and therefore cycle counter filtering is not supported. This mode can be used for debugging purposes in case e.g. that startup of a FlexRay network fails. After writing SUCC1.CMD(3-0) = 0001 the communication controller transits back to CONFIG state.

In MONITOR\_MODE the pick first valid mechanism is disabled. This means that a receive message buffer may only be configured to receive on one channel. Received frames are stored into message buffers according to frame ID and receive channel. Null frames are handled like data frames. After frame reception only status bits MBS.VFRA, MBS.VFRB, MBS.MLST, MBS.RCIS, MBS.SFIS, MBS.SYNS, MBS.NFIS, MBS.PPIS, MBS.RESS have valid values.

In MONITOR\_MODE the communication controller is not able to distinguish between CAS and MTS symbols. In case one of these symbols is received on one or both of the two channels, the flags SIR.MTSA/SIR.MTSB are set. SIR.CAS has no function in MONITOR\_MODE.

#### 26.10.5 READY State

After unlocking CONFIG state and writing SUCC1.CMD(3-0) = 0010 the communication controller enters READY state. From this state the communication controller can transit to WAKEUP state and perform a cluster wakeup or to STARTUP state to perform a coldstart or to integrate into a running cluster.

The communication controller enters this state:

- When exiting from CONFIG, WAKEUP, STARTUP, NORMAL\_ACTIVE, or NORMAL\_PASSIVE state by writing SUCC1.CMD(3-0) = 0010 (READY command).

The communication controller exits from this state:

- To CONFIG state by writing SUCC1.CMD(3-0) = 0001 (CONFIG command)
- To WAKEUP state by writing SUCC1.CMD(3-0) = 0011 (WAKEUP command)
- To STARTUP state by writing SUCC1.CMD(3-0) = 0100 (RUN command)

Internal counters and the communication controller status flags are reset when the communication controller enters STARTUP state.

---

**NOTE:** Status bits MHDS(14-0), registers TXRQ1/2/3/4, and status data stored in the Message RAM are not affected by the transition of the POC from READY to STARTUP state.

---

### 26.10.6 WAKEUP State

The description below is intended to help configuring wakeup for the FlexRay module. A detailed description of the wakeup procedure can be found in the FlexRay protocol specification v2.1 Rev. A.

The communication controller enters this state:

- When exiting from READY state by writing SUCC1.CMD(3-0) = 0011 (WAKEUP command).

The communication controller exits from this state to READY state:

- After complete non-aborted transmission of wakeup pattern
- After WUP reception
- After detecting a WUP collision
- After reception of a frame header
- By writing SUCC1.CMD(3-0) = 0010 (READY command)

The communication controller exits from this state to HALT state:

- By writing SUCC1.CMD(3-0) = 0111 (FREEZE command)

The cluster wakeup must precede the communication startup in order to ensure that all nodes in a cluster are awake. The minimum requirement for a cluster wakeup is that all bus drivers are supplied with power. A bus driver has the ability to wake up the other components of its node when it receives a wakeup pattern on its channel. At least one node in the cluster needs an external wakeup source.

The host completely controls the wakeup procedure. It is informed about the state of the cluster by the bus driver and the communication controller and configures bus guardian (if available) and communication controller to perform the cluster wakeup. The communication controller provides to the host the ability to transmit a special wakeup pattern on each of its available channels separately. The communication controller needs to recognize the wakeup pattern only during wakeup and startup phase.

Wakeup may be performed on only one channel at a time. The host has to configure the wakeup channel while the communication controller is in CONFIG state by writing bit WUCS in the SUC configuration register 1. The communication controller ensures that ongoing communication on this channel is not disturbed. The communication controller cannot guarantee that all nodes connected to the configured channel awake upon the transmission of the wakeup pattern, since these nodes cannot give feedback until the startup phase. The wakeup procedure enables single-channel devices in a two-channel system to trigger the wakeup, by only transmitting the wakeup pattern on the single channel to which they are connected. Any coldstart node that deems a system startup necessary will then wake the remaining channel before initiating communication startup.

The wakeup procedure tolerates any number of nodes simultaneously trying to wakeup a single channel and resolves this situation such that only one node transmits the pattern. Additionally the wakeup pattern is collision resilient, so even in the presence of a fault causing two nodes to simultaneously transmit a wakeup pattern, the resulting collided signal can still wake the other nodes.

After wakeup the communication controller returns to READY state and signals the change of the wakeup status to the host by setting bit SIR.WST in the status interrupt register. The wakeup status vector CCSV.WSV(2-0) can be read from the communication controller status vector register. If a valid wakeup pattern was received also either bit SIR.WUPA or bit SIR.WUPB in the status interrupt register is set.

**Figure 26-13. Structure of POC State WAKEUP**

**Table 26-7. State Transitions WAKEUP**

| T#    | Condition                                                                                                                                                                                         | From           | To             |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|----------------|
| enter | Host commands change to WAKEUP state by writing SUCC1.CMD(3-0) = 0011 (WAKEUP command)                                                                                                            | READY          | WAKEUP         |

| 2     | Received WUP on wakeup channel selected by bit SUCC1.WUCS OR frame header on either available channel                                                                                             | WAKEUP_LISTEN  | WAKEUP_STANDBY |
| 3     | Timer event                                                                                                                                                                                       | WAKEUP_LISTEN  | WAKEUP_SEND    |
| 4     | Complete, non-aborted transmission of wakeup pattern                                                                                                                                              | WAKEUP_SEND    | WAKEUP_STANDBY |
| 5     | Collision detected                                                                                                                                                                                | WAKEUP_SEND    | WAKEUP_DETECT  |
| 6     | Wakeup timer expired OR WUP detected on wakeup channel selected by bit SUCC1.WUCS OR frame header received on either available channel                                                            | WAKEUP_DETECT  | WAKEUP_STANDBY |
| exit  | Wakeup completed (after T2 or T4 or T6) OR host commands change to READY state by writing SUCC1.CMD(3-0) = 0010 (READY command). This command also resets the wakeup FSM to WAKEUP_STANDBY state. | WAKEUP         | READY          |

The WAKEUP\_LISTEN state is controlled by the wakeup timer and the wakeup noise timer. The two timers are controlled by the parameters Listen Timeout SUCC2.LT(20-0) and Listen Timeout Noise SUCC2.LTN(3-0). Listen timeout enables a fast cluster wakeup in case of a noise free environment, while listen timeout noise enables wakeup under more difficult conditions regarding noise interference.

In WAKEUP\_SEND state the communication controller transmits the wakeup pattern on the configured channel and checks for collisions. After return from wakeup the host has to bring the communication controller into STARTUP state by CHI command RUN.

In WAKEUP\_DETECT state the communication controller attempts to identify the reason for the wakeup collision detected in WAKEUP\_SEND state. The monitoring is bounded by the expiration of listen timeout as configured by SUCC2.LT(20-0) in the SUC configuration register 2. Either the detection of a wakeup pattern indicating a wakeup attempt by another node or the reception of a frame header indication existing communication, causes the direct transition to READY state. Otherwise WAKEUP\_DETECT is left after expiration of listen timeout; in this case the reason for wakeup collision is unknown.

The host has to be aware of possible failures of the wakeup and act accordingly. It is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal time it takes another coldstart node to become awake and to be configured.

The FlexRay Protocol Specification recommends that two different communication controllers shall wake the two channels.

### 26.10.6.1 Host Activities

The host must coordinate the wakeup of the two channels and must decide whether, or not, to wake a specific channel. The sending of the wakeup pattern is initiated by the host. The wakeup pattern is detected by the remote BDs and signaled to their local hosts.

Wakeup procedure controlled by host (single-channel wakeup):

- Configure the communication controller in CONFIG state
  - Select wakeup channel by programming bit SUCC1.WUCS
- Check local BDs whether a WUP was received
- Activate BD of selected wakeup channel
- Command communication controller to enter READY state
- Command communication controller to start wakeup on the configured channel by writing SUCC1.CMD(3-0) = 0011
  - communication controller enters WAKEUP\_LISTEN
  - communication controller returns to READY state and signals status of wakeup attempt to host
- Wait predefined time to allow the other nodes to wakeup and configure themselves
- Coldstart node:
  - in dual channel cluster wait for WUP on the other channel
  - Reset Coldstart Inhibit flag CCSV.CSI by writing SUCC1.CMD(3-0) = 1001 (ALLOW\_COLDSTART command)
- Command communication controller to enter startup by writing SUCC1.CMD(3-0) = 0100 (RUN command)

Wakeup procedure triggered by the bus driver:

- Wakeup recognized by bus driver
- bus driver triggers power-up of host (if required)
- bus driver signals wakeup event to host
- Host configures its local communication controller
- If necessary host commands wakeup of second channel and waits predefined time to allow the other nodes to wakeup and configure themselves
- Host commands communication controller to enter STARTUP state by writing SUCC1.CMD(3-0) = 0100 (RUN command)

### 26.10.6.2 Wake Up Pattern (WUP)

The wake up pattern (WUP) is composed of at least two wakeup symbols (WUS). Wakeup symbol and wakeup pattern are configured by the PRT configuration registers 1,2.

- Single channel wakeup, wake up symbol may not be sent on both channels at the same time
- Wakeup symbol collision resilient for up to two sending nodes (two overlapping wakeup symbols still recognizable)
- Wakeup symbol must be configured identical in all nodes of a cluster
- Wakeup symbol transmit low time configured by PRTC2.TXL(5-0)
- Wakeup symbol idle time configured by PRTC2.TXI(7-0), used to listen for activity on the bus
- A wakeup pattern composed of at least two Tx-wakeup symbols needed for wakeup
- Number of repetitions configurable by PRTC1.RWP(5-0) (2 to 63 repetitions)
- Wakeup symbol receive window length configured by PRTC1.RXW(8-0)
- Wakeup symbol receive low time configured by PRTC2.RXL(5-0)
- Wakeup symbol receive idle time configured by PRTC2.RXI(5-0)

**Figure 26-14. Timing of Wake Up Pattern**

### 26.10.7 STARTUP State

The description below is intended to help configuring startup for the FlexRay module. A detailed description of the startup procedure can be found in the FlexRay protocol specification v2.1 Rev. A.

Any node entering STARTUP state that has coldstart capability should assure that both channels attached have been awakened before initiating coldstart.

It cannot be assumed that all nodes and stars need the same amount of time to become completely awake and to be configured. Since at least two nodes are necessary to start up the cluster communication, it is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal amount of time it takes another coldstart node to become awake, to be configured and to enter startup. It may require several hundred milliseconds (depending on the hardware used) before all nodes and stars are completely awakened and configured.

Startup is performed on all channels synchronously. During startup, a node only transmits startup frames. Startup frames are both sync frames and null frames during startup.

A fault-tolerant, distributed startup strategy is specified for initial synchronization of all nodes. In general, a node may enter NORMAL\_ACTIVE state by:

- Coldstart path initiating the schedule synchronization (leading coldstart node)
- Coldstart path joining other coldstart nodes (following coldstart node)
- Integration path integrating into an existing communication schedule (all other nodes)

See also [Figure 26-15](#) for more information.

A coldstart attempt begins with the transmission of a collision avoidance symbol (CAS). Only a coldstart node that transmitted the CAS, transmits frames in the first four cycles after the CAS. It is then joined firstly by the other coldstart nodes and afterwards by all other nodes.

A coldstart node has bits SUCC1.TXST and SUCC1.TXSY set to 1. Message buffer 0 holds the key slot ID which defines the slot number where the startup frame is sent. The startup frame indicator bit is set in the frame header of the startup frame.

In clusters consisting of three or more nodes, at least three nodes shall be configured to be coldstart nodes. In clusters consisting of two nodes, both nodes must be coldstart nodes. At least two fault-free coldstart nodes are necessary for the cluster to startup.

Each startup frame must also be a sync frame; therefore each coldstart node will also be a sync node. The number of coldstart attempts is configured by SUCC1.CSA(4-0) in the SUC configuration register 1.

A non-coldstart node requires at least two startup frames from distinct nodes for integration. It may start integration before the coldstart nodes have finished their startup. It will not finish its startup until at least two coldstart nodes have finished their startup.

Both non-coldstart nodes and coldstart nodes start passive integration through the integration path as soon as they receive sync frames from which to derive the TDMA schedule information. During integration the node has to adapt its own clock to the global clock (rate and offset) and has to make its cycle time consistent with the global schedule observable at the network. Afterwards, these settings are checked for consistency with all available network nodes. The node can only leave the integration phase and actively participate in communication when these checks are passed.

### 26.10.7.2 Startup Timeouts

The communication controller supplies two different  $\mu$ T timers supporting two timeout values, startup timeout and startup noise timeout. The two timers are started when the communication controller enters the COLDSTART\_LISTEN state. The expiration of either of these timers causes the node to leave the initial sensing phase (COLDSTART\_LISTEN state) with the intention of starting up communication.

---

**NOTE:** The startup and startup noise timers are identical with the wakeup and wakeup noise timers and use the same configuration values SUCC2.LT(20-0) and SUCC2.LTN(3-0) from the SUC configuration register 2.

---

#### Startup Timeout

The startup timeout limits the listen time used by a node to determine if there is already communication between other nodes or at least one coldstart node actively requesting the integration of others. The startup timer is configured by programming SUCC2.LT(20-0) in the SUC configuration register 2.

The startup timeout time can be calculated from the contents of SUCC2.LT(20-0) (Refer to the FlexRay Protocol Specification: pdListenTimeout)

The startup timer is restarted upon:

- Entering the COLDSTART\_LISTEN state
- Both channels reaching idle state while in COLDSTART\_LISTEN state

The startup timer is stopped:

- If communication channel activity is detected on one of the configured channels while the node is in the COLDSTART\_LISTEN state
- When the COLDSTART\_LISTEN state is left

Once the startup timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The timer status is kept for further processing by the startup state machine.

#### Startup Noise Timeout

At the same time the startup timer is started for the first time (transition from STARTUP\_PREPARE state to COLDSTART\_LISTEN state), the startup noise timer is started. This additional timeout is used to improve reliability of the startup procedure in the presence of noise. The startup noise timer is configured by programming SUCC2.LTN(3-0) in the SUC configuration register 2.

The startup noise timeout time can be calculated as the product of SUCC2.LT(20-0) \* SUCC2.LTN(3-0) (Refer to the FlexRay Protocol Specification: pdListenTimeout \* gListenNoise)

The startup noise timer is restarted upon:

- Entering the COLDSTART\_LISTEN state
- Reception of correctly decoded headers or CAS symbols while the node is in COLDSTART\_LISTEN state

The startup noise timer is stopped when the COLDSTART\_LISTEN state is left.

Once the startup noise timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The status is kept for further processing by the startup state machine. Since the startup noise timer won't be restarted when random channel activity is sensed, this timeout defines the fall-back solution that guarantees that a node will try to start up the communication cluster even in the presence of noise.

### 26.10.7.3 Path of Leading Coldstart Node (Initiating Coldstart)

When a coldstart node enters COLDSTART\_LISTEN, it listens to its attached channels.

If no communication is detected, the node enters the COLDSTART\_COLLISION\_RESOLUTION state and commences a coldstart attempt. The initial transmission of a CAS symbol is succeeded by the first regular cycle. This cycle has the number zero.

From cycle zero on, the node transmits its startup frame. Since each coldstart node is allowed to perform a coldstart attempt, it may occur that several nodes simultaneously transmit the CAS symbol and enter the coldstart path. This situation is resolved during the first four cycles after CAS transmission.

As soon as a node that initiates a coldstart attempt receives a CAS symbol or a frame header during these four cycles, it re-enters the COLDSTART\_LISTEN state. Thereby, only one node remains in this path. In cycle four, other coldstart nodes begin to transmit their startup frames.

After four cycles in COLDSTART\_COLLISION\_RESOLUTION state, the node that initiated the coldstart enters the COLDSTART\_CONSISTENCY\_CHECK state. It collects all startup frames from cycle four and five and performs clock correction. If the clock correction does not deliver any errors and it has received at least one valid startup frame pair, the node leaves COLDSTART\_CONSISTENCY\_CHECK and enters NORMAL\_ACTIVE state.

The number of coldstart attempts that a node is allowed to perform is configured by SUC1.CSA(4-0) in the SUC configuration register 1. The number of remaining coldstarts attempts can be read from CCSV.RCA(4-0) of communication controller status vector register. The number of remaining attempts is reduced by one for each attempted coldstart. A node may enter the COLDSTART\_LISTEN state only if this value is larger than one and it may enter the COLDSTART\_COLLISION\_RESOLUTION state only if this value is larger than zero. If the number of coldstart attempts is one, coldstart is inhibited but integration is still possible.

#### 26.10.7.4 Path of Following Coldstart Node (Responding to Leading Coldstart Node)

When a coldstart node enters the COLDSTART\_LISTEN state, it tries to receive a valid pair of startup frames to derive its schedule and clock correction from the leading coldstart node.

As soon as a valid startup frame has been received, the INITIALIZE\_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION\_COLDSTART\_CHECK state is entered.

In INTEGRATION\_COLDSTART\_CHECK state, it is assured that the clock correction can be performed correctly and that the coldstart node from which this node has initialized its schedule is still available. The node collects all sync frames and performs clock correction in the following double-cycle. If clock correction does not signal any errors and if the node continues to receive sufficient frames from the same node it has integrated on, the COLDSTART\_JOIN state is entered.

In COLDSTART\_JOIN state, following coldstart nodes begin to transmit their own startup frames and continue to do so in subsequent cycles. Thereby, the leading coldstart node and the nodes joining it can check if their schedules agree with each other. If the clock correction signals any error, the node aborts the integration attempt. If a node in this state sees at least one valid startup frame during all even cycles in this state and at least one valid startup frame pair during all double cycles in this state, the node leaves COLDSTART\_JOIN state and enters NORMAL\_ACTIVE state. Thereby it leaves STARTUP at least one cycle after the node that initiated the coldstart.

#### 26.10.7.5 Path of Non-Coldstart Node

When a non-coldstart node enters the INTEGRATION\_LISTEN state, it listens to its attached channels.

As soon as a valid startup frame has been received the INITIALIZE\_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION\_CONSISTENCY\_CHECK state is entered.

In INTEGRATION\_CONSISTENCY\_CHECK state it is verified that the clock correction can be performed correctly and that enough coldstart nodes (at least 2) send startup frames that agree with the nodes own schedule. Clock correction is activated, and if any errors are signaled, the integration attempt is aborted.

During the first even cycle in this state, either two valid startup frames or the startup frame of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

During the first double-cycle in this state, either two valid startup frame pairs or the startup frame pair of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

If after the first double-cycle less than two valid startup frames are received within an even cycle, or less than two valid startup frame pairs are received within a double-cycle, the startup attempt is aborted.

Nodes in this state need to see two valid startup frame pairs for two consecutive double-cycles each to be allowed to leave STARTUP and enter NORMAL\_OPERATION. Consequently, they leave startup at least one double-cycle after the node that initiated the coldstart and only at the end of a cycle with an odd cycle number.

### 26.10.8 NORMAL\_ACTIVE State

As soon as the node that transmitted the first CAS symbol (resolving the potential access conflict and entering STARTUP through the coldstart path) and one additional node have entered the NORMAL\_ACTIVE state, the startup phase for the cluster has finished. In the NORMAL\_ACTIVE state, all configured messages are scheduled for transmission. This includes all data frames as well as the sync frames. Rate and offset measurement is started in all even cycles (even/odd cycle pairs required).

In NORMAL\_ACTIVE state the communication controller supports regular communication functions:

- The communication controller performs transmissions and reception on the FlexRay bus as configured
- Clock synchronization is running
- The host interface is operational

The communication controller exits from that state to:

- HALT state by writing SUCC1.CMD(3-0) = 0110 (HALT command, at the end of the current cycle)
- HALT state by writing SUCC1.CMD(3-0) = 0111 (FREEZE command, immediately)
- HALT state due to change of the error state from ACTIVE to COMM\_HALT
- NORMAL\_PASSIVE state due to change of the error state from ACTIVE to PASSIVE
- READY state by writing SUCC1.CMD(3-0) = 0010 (READY command)

### 26.10.9 NORMAL\_PASSIVE State

NORMAL\_PASSIVE state is entered from NORMAL\_ACTIVE state when the error state changes from ACTIVE to PASSIVE.

In NORMAL\_PASSIVE state, the node is able to receive all frames (node is fully synchronized and performs clock synchronization). Contrary to the NORMAL\_ACTIVE state, the node does not actively participate in communication, i.e. neither symbols nor frames are transmitted.

In NORMAL\_PASSIVE state:

- The communication controller performs reception on the FlexRay bus
- The communication controller does not transmit any frames or symbols on the FlexRay bus
- Clock synchronization is running
- The host interface is operational

The communication controller exits from this state to

- HALT state by writing SUCC1.CMD(3-0) = 0110 (HALT command, at the end of the current cycle)
- HALT state by writing SUCC1.CMD(3-0) = 0111 (FREEZE command, immediately)
- HALT state due to change of the error state from PASSIVE to COMM\_HALT
- NORMAL\_ACTIVE state due to change of the error state from PASSIVE to ACTIVE. The transition takes place when CCEV.PTAC(4-0) equals SUCC1.PTA(4-0) - 1.
- To READY state by writing SUCC1.CMD(3-0) = 0010 (READY command)

### 26.10.10 HALT State

In this state all communication (reception and transmission) is stopped.

The communication controller enters this state:

- By writing SUCC1.CMD(3-0) = 0110 (HALT command) while the communication controller is in NORMAL\_ACTIVE or NORMAL\_PASSIVE state

- By writing SUCC1.CMD(3-0) = 0111 (FREEZE command) from all states
- When exiting from NORMAL\_ACTIVE state because the clock correction failed counter reached the “maximum without clock correction fatal” limit and SUCC1.HCSE is set
- When exiting from NORMAL\_PASSIVE state because the clock correction failed counter reached the “maximum without clock correction fatal” limit and SUCC1.HCSE is set

The communication controller exits from this state to DEFAULT\_CONFIG state

- By writing SUCC1.CMD(3-0) = 0001 (CONFIG command)

When the communication controller transits from HALT state to DEFAULT\_CONFIG state all configuration and status data is maintained for analyzing purposes.

When the host writes SUCC1.CMD(3-0) = 0110 (HALT command), the communication controller sets bit CCSV.HRQ and enters HALT state at next end of cycle.

When the host writes SUCC1.CMD(3-0) = 0111 (FREEZE command), the communication controller enters HALT state immediately and sets the CCSV.FSI bit in the communication controller status vector register.

The POC state from which the transition to HALT state took place can be read from CCSV.PSL(5-0).

## 26.11 Network Management

The accrued network management (NM) vector is located in the Network Management Registers (NMV1/2/3). The communication controller performs a logical OR operation over all NM vectors out of all received valid NM frames with the Payload Preamble Indicator (PPI) bit set. Only a static frame may be configured to hold NM information. The communication controller updates the NM vector at the end of each cycle.

The length of the NM vector can be configured from 0 to 12 bytes by NEMC.NML(3-0). The NM vector length must be configured identically in all nodes of a cluster.

To configure a transmit buffer to send FlexRay frames with the PPI bit set, the PPIT bit in the header section of the corresponding transmit buffer has to be set WRHS1.PPIT. In addition the host has to write the NM information to the data section of the corresponding transmit buffer.

The evaluation of the NM vector has to be done by the application running on the host.

---

**NOTE:** In case a message buffer is configured for transmission / reception of network management frames, the payload length configured in header 2 of that message buffer should be equal or greater than the length of the NM vector configured by NEMC.NML(3-0). When the Communication Controller transits to HALT state, the cycle count is not incremented and therefore the NM vector is not updated. In this case NMV1/2/3 holds the value from the cycle before.

---

## 26.12 Filtering and Masking

Filtering is done by comparison of the configuration of assigned message buffers against current slot and cycle counter values and channel ID (channel A, B). A message buffer is only updated / transmitted if the required matches occur.

Filtering is done on:

- Slot counter
- Cycle counter
- Channel ID

The following filter combinations for acceptance / transmit filtering are allowed:

- Slot counter + Channel ID
- Slot counter + Cycle counter + Channel ID

All configured filters must match in order to store a received message in a message buffer.

---

**NOTE:** For the FIFO the acceptance filter is configured by the FIFO Rejection Filter and the FIFO Rejection Filter mask.

---

A message will be transmitted in the time slot corresponding to the configured frame ID on the configured channel(s). If cycle counter filtering is enabled the configured cycle filter value must also match.

### 26.12.1 Slot Counter Filtering

Every transmit and receive buffer contains a frame ID stored in the header section. This frame ID is compared against the current slot counter value in order to assign receive and transmit buffers to the corresponding slot.

If two or more message buffers are configured with the same frame ID and channel ID, and if they have a matching cycle counter filter value for the same slot, then the message buffer with the lowest message buffer number is used.

### 26.12.2 Cycle Counter Filtering

Cycle counter filtering is based on the notion of a cycle set. For filtering purposes, a match is detected if any one of the elements of the cycle set is matched. The cycle set is defined by the cycle code field in the header section 1 of each message buffer.

If message buffer 0 or 1 is configured to hold the startup / sync frame or the single slot frame by bits TXST, TXSY, and TSM of SUC Configuration Register 1, cycle counter filtering for message buffer 0 or 1 respectively shall be disabled.

---

**NOTE:** Sharing of a static time slot by cycle counter filtering between different nodes of a FlexRay network is not allowed.

---

The set of cycle numbers belonging to a cycle set is determined as described in [Table 26-8](#).

**Table 26-8. Definition of Cycle Set**

| Cycle Code | Matching Cycle Counter Values |                       |                 |
|------------|-------------------------------|-----------------------|-----------------|
| 0b000000x  | All cycles                    |                       |                 |
| 0b000001c  | Every second cycle            | at (cycle count)mod2  | = <b>c</b>      |
| 0b00001cc  | Every fourth cycle            | at (cycle count)mod4  | = <b>cc</b>     |
| 0b0001ccc  | Every eighth cycle            | at (cycle count)mod8  | = <b>ccc</b>    |
| 0b001cccc  | Every sixteenth cycle         | at (cycle count)mod16 | = <b>cccc</b>   |
| 0b01ccccc  | Every thirty-second cycle     | at (cycle count)mod32 | = <b>ccccc</b>  |
| 0b1cccccc  | Every sixty-fourth cycle      | at (cycle count)mod64 | = <b>cccccc</b> |

[Table 26-9](#) gives some examples for valid cycle sets to be used for cycle counter filtering.

**Table 26-9. Examples for Valid Cycle Sets**

| Cycle Code | Matching Cycle Counter Values |
|------------|-------------------------------|
| 0b0000011  | 1-3-5-7- .... -63 ↵           |
| 0b0000100  | 0-4-8-12- .... -60 ↵          |
| 0b0001110  | 6-14-22-30- .... -62 ↵        |
| 0b0011000  | 8-24-40-56 ↵                  |
| 0b0100011  | 3-35 ↵                        |
| 0b1001001  | 9 ↵                           |

The received message is stored only if the cycle counter value of the cycle during which the message is received matches an element of the receive buffer's cycle set. Other filter criteria must also be met.

The content of a transmit buffer is transmitted on the configured channel(s) when an element of the cycle set matches the current cycle counter value. Other filter criteria must also be met.

### 26.12.3 Channel ID Filtering

There is a 2-bit channel filtering field (CHA, CHB) located in the header section of each message buffer in the message RAM. It serves as a filter for receive buffers, and as a control field for transmit buffers (see [Table 26-10](#)).

**Table 26-10. Channel Filtering Configuration**

|     |     | Transmit Buffer                        | Receive Buffer                                                                         |
|-----|-----|----------------------------------------|----------------------------------------------------------------------------------------|
| CHA | CHB | Transmit frame                         | Store valid receive frame                                                              |
| 1   | 1   | On both channels (static segment only) | Received on channel A or B (store first semantically valid frame, static segment only) |
| 1   | 0   | On channel A                           | Received on channel A                                                                  |
| 0   | 1   | On channel B                           | Received on channel B                                                                  |
| 0   | 0   | No transmission                        | Ignore frame                                                                           |

The contents of a transmit buffer is transmitted on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a transmit buffer may be set up for transmission on both channels (CHA and CHB set).

Valid received frames are stored if they are received on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a receive buffer may be setup for reception on both channels (CHA and CHB set).

---

**NOTE:** If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no frames are transmitted and received frames are ignored (same function as CHA = CHB = 0)

---

### 26.12.4 FIFO Filtering

For FIFO filtering there is one rejection filter and one rejection filter mask available. The FIFO filter consists of channel filter FRF.CH(1-0), frame ID filter FRF.FID(10-0), and cycle counter filter FRF.CYF(6-0). Registers FRF and FRFM can be configured in DEFAULT\_CONFIG or CONFIG state only. The filter configuration in the header section of message buffers belonging to the FIFO is ignored.

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles not belonging to the cycle set specified by FRF.CYF(6-0), all frames are rejected.

A valid received frame is stored in the FIFO if channel ID, frame ID, and cycle counter are not rejected by the configured rejection filter and rejection filter mask, and if there is no matching dedicated receive buffer.

## 26.13 Transmit Process

### 26.13.1 Static Segment

For the static segment, if there are several messages pending for transmission, the message with the frame ID corresponding to the next sending slot is selected for transmission.

The data section of transmit buffers assigned to the static segment can be updated until the end of the preceding time slot. This means that a transfer from the input buffer has to be started by writing to the Input Buffer Command Request Register latest at this time.

### 26.13.2 Dynamic Segment

In the dynamic segment, if several messages are pending, the message with the highest priority (lowest frame ID) is selected next. In the dynamic segment different slot counter sequences on channel A and channel B are possible (concurrent sending of different frame IDs on both channels).

The data section of transmit buffers assigned to the dynamic segment can be updated until the end of the preceding slot. This means that a transfer from the input buffer has to be started by writing to the Input Buffer Command Request Register latest at this time.

The start of latest transmit configured by MHDC.SLT(12-0) in the MHD configuration register 1 defines the maximum minislot value allowed before inhibiting new frame transmission in the dynamic segment of the current cycle.

### 26.13.3 Transmit Buffers

Communication Controller message buffers can be configured as transmit buffers by programming bit CFG in the header section of the corresponding message buffer to 1 in WRHS1.

There exist the following possibilities to assign a transmit buffer to the communication controller channels:

- Static segment:
  - channel A or channel B
  - channel A and channel B
- Dynamic segment:
  - channel A or channel B

Message buffer 0 or 1 is dedicated to hold the startup frame, the sync frame, or the designated single slot frame as configured by SUCC1.TXST, SUCC1.TXSY, and SUCC1.TSM in the SUC Configuration register 1. In this case it can be reconfigured in DEFAULT\_CONFIG or CONFIG state only. This ensures that any node transmits at most one startup / sync frame per communication cycle. Transmission of startup / sync frames from other message buffers is not possible.

All other message buffers configured for transmission in static or dynamic segment are reconfigurable during runtime depending on the configuration of MRC.SEC(1-0). Due to the organization of the data partition in the message RAM (reference by data pointer), reconfiguration of the configured payload length and the data pointer in the header section of a message buffer may lead to erroneous configurations.

If a message buffer is reconfigured (header section updated) during runtime, it may happen that this message buffer is not sent out in the currently active communication cycle.

The communication controller does not have the capability to calculate the header CRC. The host is supposed to provide the header CRCs for all transmit buffers. If network management is required the host has to set the PPIT bit in the header section of the corresponding message buffer to 1 and write the network management information to the data section of the message buffer.

The payload length field configures the data payload length in 2-byte words. If the configured payload length of a static transmit buffer is shorter than the payload length configured for the static segment by MHDC.SFDL(6-0) in the message handler configuration register 1, the communication controller generates padding bytes to ensure that frames have proper physical length. The padding pattern is logical zero.

---

**NOTE:** In case of an odd payload length (PLC=1,3,5,...) the application needs to write zeros to the last 16 bit of the message buffers data section to ensure that the padding pattern is all zero.

---

Each transmit buffer provides a transmission mode flag TXM that allows the host to configure the transmission mode for the transmit buffer. If this bit is set, the transmitter operates in the single-shot mode. If this bit is cleared, the transmitter operates in the continuous mode.

In single-shot mode the Communication Controller resets the corresponding TXR flag after transmission has completed after which the host may update the transmit buffer.

In continuous mode, the Communication Controller does not reset the corresponding transmission request flag TXR after successful transmission. In this case a frame is sent out each time the filter criteria match. The TXR flag can be reset by the Host by writing the corresponding message buffer number to the IBCR register while bit IBCM.STXRH is set to 0.

If two or more transmit buffers meet the filter criteria simultaneously, the transmit buffer with the lowest message buffer number will be transmitted in the corresponding slot.

#### 26.13.4 Frame Transmission

The following steps are required to prepare a message buffer for transmission:

- Configure the transmit buffer in the Message RAM through WRHS1, WRHS2, and WRHS3
- Write the data section of the transmit buffer through WRDSn
- Transfer the configuration and message data from Input Buffer to the Message RAM by writing the number of the target message buffer to register IBCR
- If configured in the Input Buffer Command Mask (IBCM) register the Transmission request flag (TXR) for the corresponding message buffer will be set as soon as the transfer has completed, and the message buffer is ready for transmission.
- Check whether the message buffer has been transmitted by checking the TXR bits (TXR = 0) in the Transmission request 1,2,3,4 registers (single-shot mode only).

After transmission has completed, the corresponding TXR flag in the Transmission request 1,2,3,4 register is reset (single-shot mode), and, if bit MBI in the header section of the message buffer is set, flag SIR.TXI in the Status Interrupt register is set to 1. If enabled, an interrupt is generated.

#### 26.13.5 Null Frame Transmission

If in static segment the host does not set the transmission request flag before transmit time, and if there is no other transmit buffer with matching filter criteria, the communication controller transmits a null frame with the null frame indication bit set and the payload data set to zero.

In the following cases the communication controller transmits a null frame:

- If the message buffer with the lowest message buffer number matching the filter criteria does not have its transmission request flag set (TXR = 0).
- No transmit buffer configured for the slot has a cycle counter filter that matches the current cycle. In this case, no message buffer status MBS is updated.

Null frames are not transmitted in the dynamic segment.

### 26.14 Receive Process

#### 26.14.1 Dedicated Receive Buffers

A portion of the Communication Controller message buffers can be configured as dedicated receive buffers by programming bit CFG in the header section of the corresponding message buffer to 0. This can be done through the Write Header Section 1 register.

The following possibilities exist to assign a receive buffer to the Communication Controller channels:

- Static segment:
  - channel A or channel B
  - channel A and channel B (the communication controller stores the first semantically valid frame)
- Dynamic segment:
  - channel A or channel B

The communication controller transfers payload data of valid received messages from the shift registers of the FlexRay protocol controller (channel A or B) to the receive buffer with the matching filter configuration. A receive buffer stores all frame elements except the frame CRC.

All message buffers configured for reception in static or dynamic segment are reconfigurable during runtime depending on the configuration of MRC.SEC(1-0) of the Message RAM Configuration register. If a message buffer is reconfigured (header section updated) during runtime it may happen that in the currently active communication cycle a received message is lost.

If two or more receive buffers meet the filter criteria simultaneously, the receive buffer with the lowest message buffer number is updated with the received message.

### 26.14.2 Frame Reception

The following steps are required to prepare a dedicated message buffer for reception:

- Configure the receive buffer in the Message RAM through WRHS1, WRHS2, and WRHS3
- Transfer the configuration from input buffer to the message RAM by writing the number of the target message buffer to the Input Buffer Command Request (IBCR) register.

Once these steps are performed, the message buffer functions as an active receive buffer and participates in the internal acceptance filtering process, which takes place every time the communication controller receives a message. The first matching receive buffer is updated from the received message.

If a valid payload segment was stored in the data section of a message buffer, the corresponding ND flag in the NDAT1,2,3,4 registers is set, and, if bit MBI in the header section of that message buffer is set, flag SIR.RXI in the Status Interrupt Register is set to 1. If enabled, an interrupt is generated.

In case that bit ND was already set when the Message Handler updates the message buffer, bit MBS.MLST of the corresponding message buffer is set and the unprocessed message data is lost.

If no frame, a null frame, or a corrupted frame is received in a slot, the data section of the message buffer configured for this slot is not updated. In this case only the flags in the corresponding message buffer status (MBS) is updated.

When the Message Handler changes the message buffer status MBS in the header section of a message buffer, the corresponding MBC flag in the Message Buffer Status Changed 1,2,3 or 4 register is set, and if bit MBI in the header section of that message buffer is set, flag SIR.MBSI in the Status Interrupt Register is set to 1. If enabled an interrupt is generated.

If the payload length of a received frame PLR(6-0) is longer than the value programmed by PLC(6-0) in the header section of the corresponding message buffer, the data field stored in the message buffer is truncated to that length.

---

**NOTE:** The ND and MBS flags are automatically cleared by the message handler when the payload data and the header of a received message have been transferred to the output buffer, respectively.

---

### 26.14.3 Null Frame Reception

The payload segment of a received null frame is not copied into the matching dedicated receive buffer. If a null frame has been received, only the message buffer status MBS of the matching message buffer is updated from the received null frame. All bits in header 2 and 3 of the matching message buffer remain unchanged. They are updated from received data frames only.

## 26.15 FIFO Function

### 26.15.1 Description

A group of the message buffers can be configured as a cyclic First-In-First-Out (FIFO) buffer. The group of message buffers belonging to the FIFO is contiguous in the register map starting with the message buffer referenced by MRC.FFB(7-0) and ending with the message buffer referenced by MRC.LCB(7-0) in the message RAM configuration register. Up to 128 message buffers can be assigned to the FIFO.

Every valid incoming message not matching with any dedicated receive buffer but passing the programmable FIFO filter is stored into the FIFO. In this case frame ID, payload length, receive cycle count, and the message buffer status MBS of the addressed FIFO message buffer are overwritten with frame ID, payload length, receive cycle count, and the status from the received frame. Bit SIR.RFNE in the status interrupt register shows that the FIFO is not empty, bit SIR.RFCL is set when the receive FIFO fill level FSR.RFFL(7-0) is equal or greater than the critical level as configured by FCL.CL(7-0), bit EIR.RFO shows that a FIFO overrun has been detected. If enabled, interrupts are generated.

If null frames are not rejected by the FIFO rejection filter, the null frames will be treated like data frames when they are stored into the FIFO.

There are two index registers associated with the FIFO. The PUT Index register (PIDX) is an index to the next available location in the FIFO. When a new message has been received it is written into the message buffer addressed by the PIDX register. The PIDX register is then incremented and addresses the next available message buffer. If the PIDX register is incremented past the highest numbered message buffer of the FIFO, the PIDX register is loaded with the number of the first (lowest numbered) message buffer in the FIFO chain. The GET Index register (GIDX) is used to address the next message buffer of the FIFO to be read. The GIDX register is incremented after transfer of the contents of a message buffer belonging to the FIFO to the output buffer. The PUT Index register and the GET Index register are not memory mapped and are not accessible by the host CPU.

The FIFO is completely filled when the PUT index (PIDX) reaches the value of the GET index (GIDX). When the next message is written to the FIFO before the oldest message has been read, both PUT index and GET index are incremented and the new message overwrites the oldest message in the FIFO. This will set FIFO overrun flag EIR.RFO in the error interrupt register.

A FIFO not empty status is detected when the PUT index (PIDX) differs from the GET index (GIDX). In this case flag SIR.RFNE is set. This indicates that there is at least one received message in the FIFO. The FIFO empty, FIFO not empty, and the FIFO overrun states are explained in Figure 26-16 for a three message buffer FIFO.

The programmable FIFO Rejection Filter register (FRF) defines a filter pattern for messages to be rejected. The FIFO rejection filter consists of channel filter, frame ID filter, and cycle counter filter. If bit FRF.RSS is set to 1 (default), all messages received in the static segment are rejected by the FIFO. If bit FRF.RNF is set to 1 (default), received null frames are not stored in the FIFO.

The FIFO Rejection Filter mask register (FRFM) specifies which bits of the frame ID filter in the FIFO Rejection Filter register are marked don't care for rejection filtering.

**Figure 26-16. FIFO Status: Empty, Not Empty, and Overrun**

### 26.15.2 Configuration of the FIFO

(Re)configuration of message buffers belonging to the FIFO is only possible when the Communication Controller is in DEFAULT\_CONFIG or CONFIG state. While the Communication Controller is in DEFAULT\_CONFIG or CONFIG state, the FIFO function is not available.

For all message buffers belonging to the FIFO should have the same payload length configured in WRHS2.PLC(6-0) of the Write Header Section 2 register. The data pointer to the first 32-bit word in the data section of the corresponding message buffer has to be configured by WRHS3.DP(10-0).

All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask. With the exception of DP and PLC, the values configured in the header sections of the message buffers belonging to the FIFO are irrelevant.

---

**NOTE:** It is recommended to program the MBI bits of the message buffers belonging to the FIFO to 0 by WRHS1.MBI to avoid RX interrupts to be generated.

If the payload length of a received frame is longer than the value programmed by WRHS2.PLC(6-0) in the header section of the corresponding message buffer, the data field stored in a message buffer of the FIFO is truncated to that length.

---

### 26.15.3 Access to the FIFO

For FIFO access outside DEFAULT\_CONFIG and CONFIG state, the Host has to trigger a transfer from the Message RAM to the Output Buffer by writing the number of the first message buffer of the FIFO (referenced by MRC.FFB(7-0)) to the Output Buffer Command Request (OBCR) register. The message handler then transfers the message buffer addressed by the GET Index register (GIDX) to the output buffer. After this transfer the GET Index register (GIDX) is incremented.

## 26.16 Message Handling

The message handler controls data transfers between the input / output buffer and the message RAM and between the message RAM and the two transient buffer RAMs. All accesses to the internal RAMs are 32 bit accesses.

Access to the message buffers stored in the message RAM is done under control of the message handler state machine. This avoids conflicts between accesses of the two protocol controllers and the host CPU to the message RAM.

Frame IDs of message buffers assigned to the static segment have to be in the range from 1 to GTU7.NSS(9-0) as configured in the GTU configuration register 7. Frame IDs of message buffers assigned to the dynamic segment have to be in the range from GTU7.NSS(9-0) + 1 to 2047.

Received messages with no matching dedicated receive buffer (static or dynamic segment) are stored in the receive FIFO (if configured) if they pass the FIFO rejection filter.

### 26.16.1 Reconfiguration of Message Buffers

In case that an application needs to operate with more than 128 different messages, static and dynamic message buffers may be reconfigured during FlexRay operation. This is done by updating the header section of the corresponding message buffer through Input Buffer registers WRHS1,2,3.

Reconfiguration has to be enabled through control bits MRC.SEC(1-0) in the Message RAM Configuration register.

If a message buffer has not been transmitted / updated from a received frame before reconfiguration starts, the corresponding message is lost.

The point in time when a reconfigured message buffer is ready for transmission / reception according to the reconfigured frame ID depends on the current state of the slot counter when the update of the header section has completed. Therefore it may happen that a reconfigured message buffer is not transmitted / updated from a received frame in the cycle where it was reconfigured.

The Message RAM is scanned according to [Table 26-11](#) below:

**Table 26-11. Scan of Message RAM**

| Start of Scan in Slot | Scan for Slots          |
|-----------------------|-------------------------|
| 1                     | 2...15, 1 (next cycle)  |
| 8                     | 16...23, 1 (next cycle) |
| 16                    | 24...31, 1 (next cycle) |
| 24                    | 32...39, 1 (next cycle) |
| ....                  | ...                     |

A Message RAM scan is terminated with the start of NIT irrespective of it's completion. The scan of the Message RAM for slots 2 to 15 starts at the beginning of slot 1 of the current cycle. The scan of the Message RAM for slot 1 is done in the cycle before by checking in parallel to each scan of the Message RAM whether there is a message buffer configured for slot 1 of the next cycle.

The number of the first dynamic message buffer is configured by MRC.FDB(7-0) in the Message RAM Configuration register. In case a Message RAM scan starts while the Communication Controller is in dynamic segment, the scan starts with the message buffer number configured by MRC.FDB(7-0).

In case a message buffer needs to be reconfigured to be used in slot 1 of the next cycle, the following has to be considered:

- If the message buffer to be reconfigured for slot 1 is part of the Static Buffers, it will only be found if it is reconfigured before the last Message RAM scan in the static segment of the current cycle evaluates this message buffer.
- If the message buffer to be reconfigured for slot 1 is part of the Static + Dynamic Buffers, it will be found if it is reconfigured before the last Message RAM scan in the current cycle evaluates this message buffer.
- The start of NIT terminates the Message RAM scan. In case the Message RAM scan has not evaluated the reconfigured message buffer until this point in time, the message buffer will not be considered for the next cycle.

---

**NOTE:** Reconfiguration of message buffers may lead to the loss of messages and therefore has to be used very carefully. In worst case (reconfiguration in consecutive cycles) it may happen that a message buffer is never transmitted / updated from a received frame.

---

## 26.16.2 Host Access to Message RAM

The message transfer between input buffer and message RAM as well as between message RAM and output buffer is triggered by the host CPU by writing the number of the target / source message buffer to be accessed to the input or output buffer command request register (IBCR/OBCR).

The input / output buffer command mask registers can be used to write / read header and data section of the selected message buffer separately.

If bit IBCM.STXR in the input buffer command mask register is set (STXR = 1), the transmission request flag TXR of the selected message buffer is automatically set after the message buffer has been updated. If bit IBCM.STXR in the input buffer command mask register is reset (STXR = 0), the transmission request flag TXR of the selected message buffer is reset. This can be used to stop transmission from message buffers operated in continuous mode.

Input buffer (IBF) and the output buffer (OBF) are built up as a double buffer structure. One half of this double buffer structure is accessible by the host CPU (IBF host / OBF host), while the other half (IBF shadow / OBF shadow) is accessed by the message handler for data transfers between IBF / OBF and message RAM.

**Figure 26-17. Host Access to Message RAM**

#### 26.16.2.1 Data Transfer from Input Buffer to Message RAM

To configure / update a message buffer in the message RAM, the host has to write the data to WRDSn and the header to WRHS1...3. The specific action is selected by configuring the input buffer command mask IBCM.

When the host writes the number of the target message buffer in the message RAM to IBCR.IBRH(6-0) in the input buffer command request register IBCR, IBF host and IBF shadow are swapped (see [Figure 26-18](#)).

**Figure 26-18. Double Buffer Structure Input Buffer**

**Figure 26-19. Swapping of IBCM and IBCR Bits**

With this write operation the IBCR.IBSYS bit in the input buffer command request register is set to 1. The message handler then starts to transfer the contents of IBF shadow to the message buffer in the message RAM selected by IBCR.IBRS(6-0).

While the message handler transfers the data from IBF shadow to the target message buffer in the message RAM, the host may write the next message to IBF host. After the transfer between IBF shadow and the message RAM has completed, the IBCR.IBSYS bit is set back to 0 and the next transfer to the message RAM may be started by the host by writing the corresponding target message buffer number to IBCR.IBRH(6-0) in the input buffer command request register.

If a write access to IBCR.IBRH(6-0) occurs while IBCR.IBSYS is 1, IBCR.IBSYH is set to 1. After completion of the ongoing data transfer from IBF shadow to the message RAM, IBF host and IBF shadow are swapped, IBCR.IBSYH is reset to 0, IBCR.IBSYS remains set to 1, and the next transfer to the message RAM is started. In addition the message buffer numbers stored under IBCR.IBRH(6-0) and IBCR.IBRS(6-0) and the command mask flags are also swapped.

Example of a 8/16/32-bit host access sequence:

- Configure / update n-th message buffer through IBF
- Wait until IBCR.IBSYH is reset
- Write data section to WRDSn
- Write header section to WRHS1,2,3
- Write command mask: write IBCM.STXRH, IBCM.LHSH, IBCM.LDSH
- Demand data transfer to target message buffer: write IBCR.IBRH(6-0)

Configure / update further message buffer through IBF in the same way.

**NOTE:** Any write access to IBF while IBCR.IBSYH is 1 will set error flag EIR.IIBA in the Error Interrupt Register to 1. In this case the write access has no effect.

**Table 26-12. Assignment of Input Buffer Command Mask Bits**

| Position | Access | Bit   | Function                                            |
|----------|--------|-------|-----------------------------------------------------|
| 18       | r      | STXRS | Set Transmission Request shadow ongoing or finished |
| 17       | r      | LDSS  | Load Data Section shadow ongoing or finished        |
| 16       | r      | LHSS  | Load Header Section shadow ongoing or finished      |
| 2        | r/w    | STXRH | Set Transmission Request Host                       |
| 1        | r/w    | LDSh  | Load Data Section Host                              |
| 0        | r/w    | LHSH  | Load Header Section Host                            |

**Table 26-13. Assignment of Input Buffer Command Request bits**

| Pos.    | Access | Bit       | Function                                                                           |
|---------|--------|-----------|------------------------------------------------------------------------------------|
| 31      | r      | IBSYS     | IBF Busy Shadow, signals ongoing transfer from IBF shadow to message RAM           |
| 22...16 | r      | IBRS(6-0) | IBF Request Shadow, number of message buffer currently / last updated              |
| 15      | r      | IBSYH     | IBF Busy Host, transfer request pending for message buffer referenced by IBRH(6-0) |
| 6...0   | r/w    | IBRH(6-0) | IBF Request Host, number of message buffer to be updated next                      |

### 26.16.2.2 Data Transfer from Message RAM to Output Buffer

To read out a message buffer from the message RAM, the host has to write to the output buffer command mask and command request register to trigger the data transfer. After a transfer has completed the host can read the transferred data from the RDDSn, RDHS1,2,3, and MBS.

**Figure 26-20. Double Buffer Structure Output Buffer**

OBF host and OBF shadow as well as bits OBCM.RHSS, OBCM.RDSS, OBCM.RHSH, OBCM.RDSH from the output buffer command mask register and bits OBCM.OBRS(6-0), OBCM.OBRH(6-0) from the output buffer command request register are swapped under control of bits OBCR.VIEW and OBCR.REQ from the output buffer command request register.

Writing bit OBCR.REQ in the output buffer command request register to 1 copies bits OBCM.RHSS, OBCM.RDSS from the output buffer command mask register and bits OBCR.OBRS(6-0) from the output buffer command request register to an internal storage (see [Figure 26-21](#)).

After setting OBCR.REQ to 1, OBCR.OBSYS is set to 1, and the transfer of the message buffer selected by OBCR.OBRS(6-0) from the message RAM to OBF shadow is started. After the transfer between the message RAM and OBF shadow has completed, the OBCR.OBSYS bit is set back to 0. Bits OBCR.REQ and OBCR.VIEW can only be set to 1 while OBCR.OBSYS is 0.

**Figure 26-21. Swapping of OBCM and OBCR Bits**

OBF host and OBF shadow are swapped by setting bit OBCR.VIEW in the output buffer command request register to 1 while bit OBCR.OBSYS is 0 (see [Figure 26-20](#)).

In addition bits OBCR.OBRH(6-0) are swapped with the output buffer command request registers internal storage and bits OBCM.RHSH, OBCM.RDSH are swapped with the output buffer command mask registers internal storage thus assuring that the message buffer number stored in OBCR.OBRH(6-0) and the mask configuration stored in OBCM.RHSH, OBCM.RDSH matches the transferred data stored in OBF host (see [Figure 26-21](#)).

Now the host can read the transferred message buffer from OBF host while the message handler may transfer the next message from the message RAM to OBF shadow.

**NOTE:** If bits REQ and VIEW are set to 1 with the same write access while OBSYS is 0, OBSYS is automatically set to 1 and OBF shadow and OBF host are swapped. Additionally mask bits OBCM.RDSH and OBCM.RHSH are swapped with the registers internal storage to keep them attached to the corresponding Output Buffer transfer. Afterwards OBRS (6-0) is copied to the register internal storage, mask bits OBCM.RDSS and OBCM.RHSS are copied to register OBCM internal storage, and the transfer of the selected message buffer from the Message RAM to OBF shadow is started. While the transfer is ongoing the Host can read the message buffer transferred by the previous transfer from OBF Host. When the current transfer between Message RAM and OBF shadow has completed, this is signaled by setting OBSYS back to 0.

#### Example of an 8/16/32-bit host access to a single message buffer:

If a single message buffer has to be read out, two separate write accesses to OBCR.REQ and OBCR.VIEW are necessary:

- Wait until OBCR.OBSYS is reset
- Write Output Buffer Command Mask OBCM.RHSS, OBCM.RDSS
- Request transfer of message buffer to OBF Shadow by writing OBCR.OBRS(6-0) and OBCR.REQ (in case of an 8-bit Host interface, OBCR.OBRS(6-0) has to be written before OBCR.REQ).
- Wait until OBCR.OBSYS is reset
- Toggle OBF Shadow and OBF Host by writing OBCR.VIEW = 1
- Read out transferred message buffer by reading RDSSn, RDHS1,2,3, and MBS

**Example of an 8/16/32-bit host access sequence:**

Request transfer of 1st message buffer to OBF shadow

- Wait until OBCR.OBSYS is reset
- Write Output Buffer Command Mask OBCM.RHSS, OBCM.RDSS for 1st message buffer
- Request transfer of 1st message buffer to OBF Shadow by writing OBCR.OBRS(6-0) and OBCR.REQ (in case of an 8-bit Host interface, OBCR.OBRS(6-0) has to be written before OBCR.REQ).

Toggle OBF Shadow and OBF Host to read out 1st transferred message buffer and request transfer of 2nd message buffer:

Request transfer of 2nd message buffer to OBF shadow, read out 1st message buffer from OBF host

- Wait until OBCR.OBSYS is reset
- Write Output Buffer Command Mask OBCM.RHSS, OBCM.RDSS for 2nd message buffer
- Toggle OBF Shadow and OBF Host and start transfer of 2nd message buffer to OBF Shadow simultaneously by writing OBCR.OBRS(6-0) of 2nd message buffer, OBCR.REQ, and OBCR.VIEW (in case of an 8-bit Host interface, OBCR.OBRS(6-0) has to be written before OBCR.REQ and OBCR.VIEW).
- Read out 1st transferred message buffer by reading RDDSn, RDHS13, and MBS

For further transfers continue the same way.

Demand access to last requested message buffer without request of another message buffer:

- Wait until OBCR.OBSYS is reset
- Demand access to last transferred message buffer by writing OBCR.VIEW
- Read out last transferred message buffer by reading RDDSn, RDHS1,2,3, and MBS

**Table 26-14. Assignment of Output Buffer Command Mask Bits**

| Position | Access | Bit  | Function                        |
|----------|--------|------|---------------------------------|
| 17       | r      | RDSH | Read Data Section Host access   |
| 16       | r      | RHSH | Read Header Section Host access |
| 1        | r/w    | RDSS | Read Data Section Shadow        |
| 0        | r/w    | RHSS | Read Header Section Shadow      |

**Table 26-15. Assignment of Output Buffer Command Request Bits**

| Position | Access | Bit       | Function                                                                 |

### 26.16.3 FlexRay Protocol Controller Access to Message RAM

The two transient buffer RAMs (TBF A,B) are used to buffer the data for transfer between the two FlexRay channel protocol controllers and the message RAM.

Each transient buffer RAM is built up as a double buffer, able to store two complete FlexRay messages. There is always one buffer assigned to the corresponding protocol controller while the other one is accessible by the message handler.

If e.g. the message handler writes the next message to be sent to transient buffer Tx, the FlexRay Channel protocol controller can access transient buffer Rx to store the message it is currently receiving. During transmission of the message stored in transient buffer Tx, the message handler transfers the last received message stored in transient buffer Rx to the message RAM (if it passes acceptance filtering) and updates the corresponding message buffer.

Data transfers between the transient buffer RAMs and the shift registers of the FlexRay channel protocol controllers are done in words of 32 bit. This enables the use of a 32 bit shift register independent of the length of the FlexRay messages.

**Figure 26-22. Access to Transient Buffer RAMs**

## 26.17 Module RAMs

The FlexRay module contains the following RAM portions:

- Message RAM
- Transient Buffer RAM Channel A (TBF A)
- Transient Buffer RAM Channel B (TBF B)
- Input Buffer (IBF)
- Input Buffer Shadow (IBFS)
- Output Buffer (OBF)
- Output Buffer Shadow (OBFS)
- Transfer Configuration RAM (TCR)

All RAMs except the TCR are part of the Communication Controller core.

### 26.17.1 Message RAM

To avoid conflicts between host access to the message RAM and FlexRay message reception / transmission, the host CPU cannot directly access the message buffers in the message RAM. These accesses are handled through the input and output buffers. The message RAM is able to store up to 128 message buffers depending on the configured payload length.

The message RAM has a structure as shown in [Figure 26-23](#).

The data partition is allowed to start at Message RAM word number:  $(MRC.LCB + 1) \cdot 4$

**Figure 26-23. Configuration Example of Message Buffers in the Message RAM**

#### Header Partition

Stores header segments of FlexRay frames:

- Supports a maximum of 128 message buffers
- Each message buffer has a header of four 32 bit words
- Header 3 of each message buffer holds the 11-bit data pointer to the corresponding data section in the data partition

#### Data Partition

Flexible storage of data sections with different length. Some maximum values are:

- 30 message buffers with 254 byte data section each
- Or 56 message buffers with 128 byte data section each
- Or 128 message buffers with 48 byte data section each

**Restriction:** header partition + data partition may not occupy more than 2048 x 32 bit words.

#### 26.17.1.1 Header Partition

The elements used for configuration of a message buffer as well as the current message buffer status are stored in the header partition of the message RAM as listed in [Figure 26-24](#) below. Configuration of the header sections of the message buffers is done through IBF (Write Header Section 1,2,3). Read access to the header sections is done through OBF (read header section 1,2,3 + message buffer status). The data pointer has to be calculated by the programmer to define the starting point of the data section for the corresponding message buffer in the data partition of the message RAM. The data pointer should not be modified during runtime. For message buffers belonging to the receive FIFO (re)configuration should be done in DEFAULT\_CONFIG or CONFIG state only.

The header section of each message buffer occupies four 32 bit words in the header partition of the message RAM. The header of message buffer 0 starts with the first word in the message RAM.

For transmit buffers the Header CRC has to be calculated by the host CPU.

Payload length received (PLR(6-0)), receive cycle count (RCC(5-0)), Received on Channel Indication (RCI), Startup Frame Indication bit (SFI), sync bit (SYN), null frame indication bit (NFI), payload preamble indication bit (PPI), and reserved bit (RES) are only updated from received valid data frames only.

Header word 3 of each configured message buffer holds the corresponding message buffer status MBS.

**Figure 26-24. Header Section of Message Buffer in Message RAM**

| Bit Word | 31 | 30                      | 29               | 28               | 27               | 26               | 25               | 24               | 23                        | 22         | 21                  | 20 | 19 | 18 | 17 | 16 | 15          | 14          | 13 | 12                                                                 | 11          | 10           | 9                | 8                | 7                | 6                | 5                | 4                | 3                | 2                | 1                | 0                |

|  | Message Buffer Control      |
|  | Message RAM Configuration   |
|  | Updated from received Frame |
|  | Message Buffer Status       |
|  | unused                      |

### Header 1 (Word 0)

Write access through WRHS1, read access through RDHS1:

- Frame ID- Slot counter filtering configuration
- Cycle Code- Cycle counter filtering configuration
- CHA, CHB- Channel filtering configuration
- CFG- Message buffer configuration: receive / transmit
- PPIT- Payload Preamble Indicator Transmit
- TXM- Transmit mode configuration: single-shot / continuous
- MBI- Message buffer receive / transmit interrupt enable

### Header 2 (Word 1)

Write access through WRHS2, read access through RDHS2:

- Header CRC Transmit Buffer: Configured by the host (calculated from frame header)
  - Receive Buffer: Updated from received frame
- Payload Length Configured: Length of data section (2-byte words) as configured by the host
- Payload Length Received: Length of payload segment (2-byte words) stored from received frame

### Header 3 (Word 2)

Write access through WRHS3, read access through RDHS3:

- Data Pointer- Pointer to the beginning of the corresponding data section in the data partition

Read access through RDHS3, valid for receive buffers only, updated from received frames:

- Receive Cycle Count - Cycle count from received frame
- RCI- Received on Channel Indicator
- SFI- Startup Frame Indicator
- SYN- Sync Frame Indicator
- NFI- Null Frame Indicator
- PPI- Payload Preamble Indicator
- RES- REServed bit

### Message Buffer Status MBS (Word 3)

Read access through MBS, updated by the communication controller at the end of the configured slot.

- VFRA- Valid Frame received on channel A
- VFRB- Valid Frame received on channel B
- SEOA- Syntax Error Observed on channel A
- SEOB- Syntax Error Observed on channel B
- CEOA- Content Error Observed on channel A
- CEOb- Content Error Observed on channel B
- SVOA- Slot Boundary Violation Observed on channel A
- SVOB- Slot Boundary Violation Observed on channel B
- TCIA- Transmission Conflict Indication channel A
- TCIB- Transmission Conflict Indication channel B
- ESA- Empty Slot Channel A
- ESB- Empty Slot Channel B
- MLST- Message Lost
- FTA- Frame Transmitted on Channel A
- FTB- Frame Transmitted on Channel B
- Cycle Count Status- Current cycle count when status was updated
- RCIS- Received on Channel Indicator Status
- SFIS- Startup Frame Indication Status
- SYNS- Sync Frame Indicator Status
- NFIS- Null Frame Indicator Status
- PPIS- Payload Preamble Indicator Status
- RESS- Reserved Bit Status

#### 26.17.1.2 Data Partition

The data partition of the message RAM stores the data sections of the message buffers configured for reception / transmission as defined in the header partition. The number of data bytes for each message buffer can vary from 0 to 254. In order to optimize the data transfer between the shift registers of the two FlexRay protocol controllers and the message RAM as well as between the host interface and the message RAM, the physical width of the message RAM is word wise (4 bytes).

The data partition starts right after the last word of the header partition. When configuring the message buffers in the message RAM the programmer has to assure that the data pointers point to addresses within the data partition.

Figure 26-25 below shows an example how the payload of the configured message buffers can be stored in the data partition of the message RAM. Message buffers 0 to 2 are static buffers with a payload of 3, whereas message buffers 3 to n are dynamic buffers with variable payload.

The beginning of a message buffer's data section is determined by the data pointer and the payload length configured in the message buffer's header section. This enables a flexible usage of the available RAM space for storage of message buffers with different data lengths.

The storage of the payload data is word aligned. If the size of a message buffer payload is an odd number of 2-byte words, the remaining 16 bits in the last 32-bit word are unused (see Figure 26-25).

**Figure 26-25. Example Structure of Data Partition in Message RAM**

### 26.17.2 Parity Check

In order to assure the integrity of the data stored in the different RAM blocks of the module (message RAM, 2 transient buffer RAMs, 2 input buffer RAMs, 2 output buffer RAMs, Transfer Configuration RAM), the FlexRay module RAMs are parity protected.

The RAM blocks are parity protected and the parity protection cannot be disabled. Only the Transfer Configuration RAM has the exceptional functionality that parity protection can either be switched on or off by writing a 4 bit key to the dedicated parity lock bits (PEL(3-0)) in the Global Control Register (GCS/R) of the Transfer Unit register frame. By default the parity protection of the TCR is switched off.

The following Figure 26-26 shows the structure of the parity concerning enabling/disabling and error indication.

Figure 26-26. Parity Structure

**NOTE:** For the seven RAM blocks of the Communication Controller portion (message RAM, 2 transient buffer RAMs, 2 input buffer RAMs and 2 output buffer RAMs) parity protection is switched on, which can be selected by the parity lock bits (PEL(3-0)). Parity protection cannot be switched off completely. For the TCR of the Transfer Unit actually the parity error generation will be switched on and off by the parity lock bits, the parity generation itself remains always on.

The following sections describe the protection for the Communication Controller related RAM blocks.

All the RAM blocks have a parity generator and a parity checker attached as shown in Figure 26-27. When data is written to a RAM block, the local parity generator generates the corresponding parity information.

The parity is checked each time a data word is read from any of the RAM blocks. The module internal data buses have a width of 32 bits. If a parity error is detected, the PERR error flag is set in the error interrupt register (EIR). Additionally a parity error interrupt can be generated, if enabled by the PERRE bit in the error interrupt enable register (EIES/R). The faulty message buffer number together with the information of the failing RAM can be read from the message handler status (MHDS) register.

Figure 26-27 shows the data paths between the RAM blocks and the parity generators / checkers.

**Figure 26-27. Parity Generation and Check**

**NOTE:** The parity generator and parity checker are not part of the RAM blocks, but of the RAM access logic.

For parity generation, the FlexRay module uses an even parity (with an even number of ones in the 32-bit data word a zero parity bit is generated).

When a parity error has been detected the following actions will be performed:

In all cases

- The corresponding error flag in the message handler status (MHDS) register is set and the faulty message buffer is indicated.
- The error flag EIR.PERR in the error interrupt register is set, and if enabled, a module interrupt to the CPU will be generated.

Additionally in specific cases of parity errors

1. Parity error during data transfer from input buffer RAM 1,2 ⇒ message RAM

(a) Transfer of header and/or data section and parity error occurs during header and/or data section transfer to message RAM:

- MHDS.PIBF bit is set
- MHDS.FMBD bit is set to indicate that MHDS.FMB(6-0) points to a faulty message buffer
- MHDS.FMB(6-0) indicates the number of the faulty message buffer
- Header and/or data section of the corresponding message buffer is updated
- Transmission request for the corresponding message buffer is not set (no transfer to the FlexRay bus)

- (b) Transfer of data section only and parity error occurs when reading header section of the corresponding message buffer from the message RAM.
    - MHDS.PMR bit is set
    - MHDS.FMBD bit is set to indicate that MHDS.FMB(6-0) points to a faulty message buffer
    - MHDS.FMB(6-0) indicates the number of the faulty message buffer
    - The data section of the corresponding message buffer is not updated
    - Transmission request for the corresponding message buffer is not set (no transfer to the FlexRay bus)
2. Parity error during host CPU reading input buffer RAM 1,2
  - MHDS.PIBF bit is set
3. Parity error during scan of header sections in message RAM
  - MHDS.PMR bit is set
  - MHDS.FMBD bit is set to indicate that MHDS.FMB(6-0) points to a faulty message buffer
  - MHDS.FMB(6-0) indicates the number of the faulty message buffer
  - Ignore message buffer (the transfer of the message buffer is skipped)
4. Parity error during data transfer from message RAM to transient buffer RAM 1,2
  - MHDS.PMR bit is set
  - MHDS.FMBD bit is set to indicate that MHDS.FMB(6-0) points to the faulty message buffer
  - MHDS.FMB(6-0) indicates the number of the faulty message buffer
  - Frame not transmitted, frames already in transmission are invalidated by setting the frame CRC to zero
5. Parity error during data transfer from transient buffer RAM 1,2 to protocol controller 1, 2
  - MHDS.PTBF1,2 bit is set
  - Frames already in transmission are invalidated by setting the frame CRC to zero
6. Parity error during data transfer from transient buffer RAM 1,2 to message RAM
  - (a) Parity error when reading header section of corresponding message buffer from message RAM
    - MHDS.PMR bit is set
    - MHDS.FMBD bit is set to indicate that MHDS.FMB(6-0) points to a faulty message buffer
    - MHDS.FMB(6-0) indicates the number of the faulty message buffer
    - The data section of the corresponding message buffer is not updated
  - (b) Parity error when reading transient buffer RAM 1,2:
    - MHDS.PTBF1,2 bit is set
    - MHDS.FMBD bit is set to indicate that MHDS.FMB(6-0) points to a faulty message buffer
    - MHDS.FMB(6-0) indicates the number of the faulty message buffer
    - The data section of the corresponding message buffer is updated
7. Parity error during data transfer from message RAM to output buffer RAM
  - MHDS.PMR bit is set
  - MHDS.FMBD bit is set to indicate that MHDS.FMB(6-0) points to faulty message buffer
  - MHDS.FMB(6-0) indicates the number of the faulty message buffer
  - Header and/or data section of the output buffer is updated, but should not be used by the host CPU
8. Parity error during host CPU reading output buffer RAM 1,2
  - MHDS.POBF bit is set
9. Parity error during data read of transient buffer RAM 1,2When a parity error occurs during the Message Handler reads a frame with network management information (PPI = 1) from the transient buffer RAM 1,2 the corresponding network management vector register NMV1,2,3 is not updated from that frame.

### 26.17.2.1 Host Handling of Parity Errors

Parity errors caused by transient bit flips can be fixed by:

#### **Self-healing**

Parity errors located in

- Input Buffer RAM 1,2
- Output Buffer RAM 1,2
- Data Section of Message RAM
- Transient Buffer RAM A
- Transient Buffer RAM B
- Transfer Configuration RAM (TCR)

are overwritten with the next write access to the disturbed bit(s) caused by host access or by FlexRay communication.

#### **CLEAR\_RAMs Command**

When called in DEFAULT\_CONFIG or CONFIG state POC command CLEAR\_RAMs initializes all module-internal RAMs to zero and the parity bits are initialized accordingly, depending what mode is enabled.

#### **Temporary Unlocking of Header Section**

A parity error in the header section of a locked message buffer can be fixed by a transfer from the input buffer to the locked buffer header section. For this transfer, the write-access to the IBCR (specifying the message buffer number) must be immediately preceded by the unlock sequence normally used to leave CONFIG state. For that single transfer the corresponding message buffer header is unlocked, regardless whether it belongs to the FIFO or whether its locking is controlled by MRC.SEC(1-0), and will be updated with new data.

---

**NOTE:** In case above methods do not work, it is recommended to execute the PBIST test at device level to confirm a hard error in the module internal RAMs.

---

## 26.18 Interrupts

This section describes the transfer unit interrupts and the communication controller interrupts.

### 26.18.1 Transfer Unit Interrupts

#### 26.18.1.1 Interrupt Structure

For transfer interrupts, one enable bit is provided for each bit in the transfer occurred status registers. Maskable error interrupts are possible for all error conditions except parity error and memory protection error.

The parity error and the memory protection error have separate non-maskable lines. Both turn off the Transfer Unit after finishing the current word access cycle.

The following [Figure 26-28](#) shows the interrupt structure of the FlexRay Transfer Unit.

Figure 26-28. Transfer Unit Interrupt Structure

### 26.18.1.2 Enable Interrupts

TSMIES/R and TCCIES/R control the buffer transfer interrupts for each buffer in both directions. The TEIRES/R registers controls the maskable error interrupt sources which are:

- VBUS transaction errors  
If an error occurs during VBUS read or write transfer a error interrupt will be generated.
- Forbidden access to IBF or OBF  
Since host accesses to communication controller through the IBF and the OBF (0x400-0x7FF) are forbidden, as long as the Transfer Unit State Machine is enabled, accesses will be ignored and an error interrupt will be generated.
- Transfer not ready when TBA should be loaded  
When a transfer is ongoing/pending during base address reload on FlexRay communication cycle start (only occurs if NTBA != TBA) the TBA will not be loaded and an error interrupt will be generated.

The transfer interrupts use a separate interrupt line (TU\_int0) than the error interrupts (TU\_int1).

### 26.18.1.3 Interrupt Flags

The TSMO and TCCO flags indicate buffer transfer status interrupts whereas the TEIF flags indicate interrupt sources for maskable and non-maskable error interrupts.

The error interrupt flags are set by the Transfer Unit State Machine and can be cleared by the CPU by writing a '1'. If the CPU clears the flag, while the Transfer Unit State Machine sets it at the same time, the flag remains set.

### 26.18.1.4 Non Maskable Error Indication

Memory protection violation and uncorrectable TCR error have their own non maskable error lines, which can be connected to the Vectored Interrupt Module (VIM) and/or the Error Signaling Module (ESM). Please refer to the specific device data sheet on the hookup.

- If a memory protection violation occurs the Memory Protection Violation Error (TU\_MPV\_err) line will be activated.
- If a uncorrectable TCR error occurs while accessing the TCR, the Parity Error (TU\_UCT\_err) line will be activated.

## 26.18.2 Communication Controller Interrupts

In general, interrupts provide a close link to the protocol timing as they are triggered almost immediately when an error or status change is detected by the controller, a frame is received or transmitted, a configured timer interrupt is activated, or a stop watch event occurred. This enables the host CPU to react very quickly on specific error conditions, status changes, or timer events. To remain flexible though, the communication controller supports disable / enable controls for each individual interrupt source separately.

An interrupt may be triggered, for example when

- a frame is received or transmitted
- an error was detected
- a status flag is set
- a timer reaches a preconfigured value
- a message transfer from input buffer to message RAM or from message RAM to output buffer has completed
- a stop watch event occurred

**Figure 26-29. Interrupt Structure**

Tracking status and generating interrupts when a status change or an error occurs are two independent tasks. Independent of an interrupt being enabled, the corresponding status is tracked and indicated by the Communication Controller. The host has access to the current status and error information by reading the error interrupt register and the status interrupt register.

The interrupt lines to the host, CC\_int0 and CC\_int1, are controlled by the enabled interrupts. In addition each of the two interrupt lines to the host CPU can be enabled / disabled separately by programming bit EINT0 and EINT1 in the Interrupt Line Enable register.

The two timer interrupts generated by interrupt timer 0 and 1 are available on pins CC\_tint0 and CC\_tint1. They can be configured via the timer 0 and timer 1 configuration register.

When a transfer between IBF / OBF and the Message RAM has completed bit SIR.TIBC or SIR.TOBC is set.

**Table 26-16. Module Interrupt Flags and Interrupt Line Enable**

| Register | Bit   | Function                               |
|----------|-------|----------------------------------------|
| EIR      | PEMC  | Protocol error Mode Changed            |
|          | CNA   | Command Not Valid                      |
|          | SFBM  | Sync Frames Below Minimum              |
|          | SFO   | Sync Frame Overflow                    |
|          | CCF   | Clock Correction Failure               |
|          | CCL   | CHI Command Locked                     |
|          | PERR  | Parity error                           |
|          | RFO   | Receive FIFO Overrun                   |
|          | EFA   | Empty FIFO Access                      |
|          | IIBA  | Illegal Input Buffer Access            |
|          | IOBA  | Illegal Output Buffer Access           |
|          | MHF   | Message Handler Constraints Flag       |
|          | EDA   | Error Detected on Channel A            |
|          | LTVA  | Latest Transmit Violation Channel A    |
|          | TABA  | Transmission Across Boundary Channel A |
|          | EDB   | Error Detected on Channel B            |
|          | LTVB  | Latest Transmit Violation Channel B    |
|          | TABB  | Transmission Across Boundary Channel B |
| SIR      | WST   | Wakeup Status                          |

|          | WUPB  | Wakeup Pattern Channel B               |
|          | MTSB  | MTS Received on Channel B              |
| ILE      | EINT0 | Enable Interrupt Line 0                |
|          | EINT1 | Enable Interrupt Line 1                |

## 26.19 FlexRay Module Registers

### 26.19.1 Transfer Unit Registers

All registers are organized as 32-bit registers. 32/16/8-bit accesses are supported. For FlexRayTU transfers only, 4x32-bit data packages are supported.

The Transfer Unit State Machine registers use the offset address range 00 to 1FCh.

Transfer Configuration RAM uses the offset address range 00 to 1FCh in normal mode and 00 to 3FCh in parity test mode.

**Table 26-17. Transfer Unit Register Summary**

| Offset Address | Acronym  | Register Description                                 | Section                            |
|----------------|----------|------------------------------------------------------|------------------------------------|
| 00             | GSN0     | Global Static Number 0                               | <a href="#">Section 26.19.1.1</a>  |

### 26.19.1.1 Global Static Number 0 (GSN0)

This register contains a constant to check correctness of data transfers.

**Figure 26-30. Global Static Number 0 (GSN0) [offset\_TU = 00h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-18. Global Static Number 0 (GSN0) Field Descriptions**

| Bit   | Field        | Value   | Description                  |
|-------|--------------|---------|------------------------------|
| 31-16 | Data_A(15-0) | 0-FFFFh |                              |
| 15-0  | Data_B(15-0) | 0-FFFFh | (complement of Data_A(15-0)) |

### 26.19.1.2 Global Static Number 1 (GSN1)

This register contains a constant to check correctness of data transfers.

**Figure 26-31. Global Static Number 1 (GSN1) [offset\_TU = 04h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-19. Global Static Number 1 (GSN1) Field Descriptions**

| Bit   | Field        | Value   | Description                  |
|-------|--------------|---------|------------------------------|
| 31-16 | Data_C(15-0) | 0-FFFFh |                              |
| 15-0  | Data_D(15-0) | 0-FFFFh | (complement of Data_C(15-0)) |

### 26.19.1.3 Global Control Set/Reset (GCS/R)

The GCx Registers reflects the configuration mode and allows to configure the basic Transfer Unit behavior.

The GCx registers consist of a set register (GCS) and a reset register (GCR). Bits are set by writing '1' to GCS and reset by writing '1' to GCR. Writing a '0' has no effect. Reading from both addresses will result in the same value.

**Figure 26-32. Global Control Set (GCS) [offset\_TU = 10h]**

After deassertion, the Transfer Unit State Machine continues at the point it was halted before. No reconfiguration is required.<br>Transfer Unit not halted<br>Transfer Unit halted<br><b>Note: If the Transfer Unit State Machine halts, all mirroring registers contained the last transfer not the current transfer information.</b>  |
| 0    | TUE      | 0<br>1 | Transfer Unit Enabled<br>Enable/Disable transfer unit.<br>Transfer Unit disabled, reset Transfer Unit State Machine, completion of the current VBUS transfer cycle but data could be corrupt.<br>Transfer Unit enabled<br><b>Note: Before switching on the Transfer Unit, the registers must be set up. After re-enabling of the Transfer Unit State Machine the contents of the module registers and the TCR is still valid (assuming it was continuously powered).</b> |

### 26.19.1.4 Transfer Status Current Buffer (TSCB)

The Transfer Status Current Buffer displays the current buffer in progress and indicates if the Transfer Unit State Machine is idle and is halt. The IDLE flag is cleared by writing a '1' to it.

**Figure 26-34. Transfer Status Current Buffer (TSCB) [offset\_TU = 18h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-21. Transfer Status Current Buffer (TSCB) Field Descriptions**

| Bit   | Field     | Value | Description                                                                                                                                                                                                                                          |

### 26.19.1.7 Transfer Base Address (TBA)

The Transfer Base Address register holds a 32-bit aligned 32-bit base-pointer, which defines the base address for the data to be transferred.

**NOTE:** A write to this register also modifies the NTBA register.

**Figure 26-37. Transfer Base Address (TBA) [offset\_TU = 24h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-24. Transfer Base Address (TBA) Field Descriptions**

| Bit  | Field     | Value        | Description                                                                                                        |
|------|-----------|--------------|--------------------------------------------------------------------------------------------------------------------|
| 31-0 | TBA(31-0) | 0-FFFF FFFFh | Transfer Base Address. 32-bit base pointer, 2 LSB are not significant (32-bit accesses only) and will always be 0. |

### 26.19.1.8 Next Transfer Base Address (NTBA)

The Next Transfer Base Address hold a 32bit aligned 32bit base-pointer to be loaded into TBA during next cycle start.

**NOTE:** A write on TBA register also modifies the NTBA register.

**Figure 26-38. Next Transfer Base Address (NTBA) [offset\_TU = 28h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-25. Next Transfer Base Address (NTBA) Field Descriptions**

| Bit  | Field      | Value        | Description                                                                                                       |
|------|------------|--------------|-------------------------------------------------------------------------------------------------------------------|
| 31-0 | nTBA(31-0) | 0-FFFF FFFFh | Next Transfer Base Address32-bit base pointer, 2 LSB are not significant (32-bit accesses only) will always be 0. |

### 26.19.1.9 Base Address of Mirrored Status (BAMS)

The Base Address of Mirrored Status hold a 32-bit aligned 32-bit base-pointer to be use for mirror transactions. Further details about the transfer mirror mechanism can be found in the Transfer Mirror Function section.

**Figure 26-39. Base Address of Mirrored Status (BAMS) [offset\_TU = 2Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-26. Base Address of Mirrored Status (BAMS) Field Descriptions**

| Bit  | Field      | Value        | Description                                                                                                            |
|------|------------|--------------|------------------------------------------------------------------------------------------------------------------------|
| 31-0 | BAMS(31-0) | 0-FFFF FFFFh | Base Address of Mirrored Status32-bit base pointer, 2 LSB are not significant (32-bit accesses only) will always be 0. |

### 26.19.1.10 Start Address of Memory Protection (SAMP)

The Start Address of Memory Protection hold a 32bit address.

**Figure 26-40. Start Address of Memory Protection (SAMP) [offset\_TU = 30h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-27. Start Address of Memory Protection (SAMP) Field Descriptions**

| Bit  | Field      | Value        | Description                                                                                                                                                                                                                                |

### 26.19.1.11 End Address of Memory Protection (EAMP)

The End Address of Memory Protection hold a 32bit address.

**Figure 26-41. End Address of Memory Protection (EAMP) [offset\_TU = 34h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-28. End Address of Memory Protection (EAMP) Field Descriptions**

| Bit  | Field      | Value        | Description                                                                                                                                                                                                                   |
|------|------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | EAMP(31-0) | 0-FFFF FFFFh | End Address Memory Protection.<br>End address of the memory area, which allows read and write accesses for the Transfer Unit State Machine.32-bit address, 2 LSB are not significant (32-bit accesses only) will always be 0. |

### 26.19.1.12 Transfer to System Memory Occurred 1/2/3/4 (TSMO1-4)

The Transfer to System Memory Occurred register reflects the message buffer transfer status for a transfer transaction to the system memory. Four 32-bit registers reflect all possible 128 message buffers.

**NOTE:** Writing 1 will clear a bit. Writing 0 will leave a bit unchanged.

**Figure 26-42. Transfer to System Memory Occurred 1 (TSMO1) [offset\_TU = 40h]**

LEGEND: R/W = Read/Write; R = Read only; C = Clear; -n = value after reset

**Table 26-29. Transfer to System Memory Occurred 1 (TSMO1) Field Descriptions**

| Bit  | Field       | Value | Description                                    |
|------|-------------|-------|------------------------------------------------|
| 31-0 | TSMO1(31-0) |       | Transfer to System Memory Occurred Register 1. |
|      |             | 0     | No transfer occurred.                          |
|      |             | 1     | Transfer occurred.                             |

**Figure 26-43. Transfer to System Memory Occurred 2 (TSMO2) [offset\_TU = 44h]**

LEGEND: R/W = Read/Write; R = Read only; C = Clear; -n = value after reset

**Table 26-30. Transfer to System Memory Occurred 2 (TSMO2) Field Descriptions**

### 26.19.1.13 Transfer to Communication Controller Occurred 1/2/3/4 (TCCO1-4)

The Transfer to Communication Controller Occurred reflects the message buffer transfer status for a VBUSP master transfer transaction from the system memory. Four 32-bit registers reflect all possible 128 message buffers.

**NOTE:** Writing 1 will clear a bit. Writing 0 will leave a bit unchanged.

**Figure 26-46. Transfer to Communication Controller Occurred 1 (TCCO1) [offset\_TU = 50h]**

LEGEND: R/W = Read/Write; R = Read only; C = Clear; -n = value after reset

### 26.19.1.14 Transfer Occurred Offset (TOOFF)

The Transfer Occurred Offset register contains the offset vector to the highest prior pending transfer occurred interrupt and the transfer direction.

After a read access the transfer occurred flag is cleared and the register contents will be updated automatically.

**Figure 26-50. Transfer Occurred Offset (TOOFF) [offset\_TU = 60h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-37. (Transfer Occurred Offset (TOOFF) Field Descriptions**

### 26.19.1.15 Parity Error Address (PEADR)

After a parity error in the Transfer Configuration RAM occurred, the affected address is stored in this not resettable register.

The contents of the Parity Error Address register as well as the PE bit in the Transfer Error Interrupt Flag (TEIF) register is cleared automatically when reading the Parity Error Address register.

**Figure 26-51. Parity Error Address (PEADR) [offset\_TU = 70h]**

|          |  |   |   |          |
|----------|--|---|---|----------|
| 31       |  | 9 | 8 | 0        |
| Reserved |  |   |   | ADR(8-0) |
| R-0      |  |   |   | R/C-U    |

LEGEND: R/W = Read/Write; R = Read only; C = Clear; U = Undefined; -n = value after reset

**NOTE:** A parity error can only be indicated by the PE bit of TEIR(16) register when PEADR is cleared. Since the contents of PEADR is undefined after reset, it is recommended to clear the register by reading it.

**Table 26-38. Parity Error Address (PEADR) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                                                                      |

| 8-0  | ADR(8-0) | 0-1FFh | Address of failing TCR location.<br>ADR(8-2) is the TCR word address were the parity error occurred.<br>ADR(1-0) can be used to find the failing byte in the TCR word the parity error occurred. |

**Table 26-39. Coding of Parity Error Address**

| Parity Error in Byte 2 | Parity Error in Byte 1 | Parity Error in Byte 0 (LSB) | ADR1 | ADR0 |
|------------------------|------------------------|------------------------------|------|------|
| -                      | -                      | 1                            | 0    | 1    |
| -                      | 1                      | 0                            | 1    | 0    |
| 1                      | 0                      | 0                            | 1    | 1    |
| 0                      | 0                      | 0                            | 0    | 0    |

**NOTE:** No Byte 3 is defined in TCR.

#### 26.19.1.16 Transfer Error Interrupt Flag (TEIF)

The Transfer Error Interrupt Flag register includes the Transfer Unit error flags. The bits in the TEIF are cleared by writing a 1.

**Figure 26-52. Transfer Error Interrupt Flag (TEIF) [offset\_TU = 74h]**

**Table 26-40. Transfer Error Interrupt Flag (TEIF) Field Descriptions (continued)**

| Bit | Field | Value | Description                                                                                    |
|-----|-------|-------|------------------------------------------------------------------------------------------------|
|     |       | 1     | Transfer is not ready on communication cycle start and therefore NTBA is not loaded to TBA.    |
| 0   | FAC   | 0     | Forbidden Access.                                                                              |
|     |       | 0     | No forbidden access occurred.                                                                  |
|     |       | 1     | A forbidden CPU access to IBF or OBF occurred when the Transfer Unit State Machine is enabled. |

**NOTE:** Memory Protection Violation (MPV) and Parity Error (PE) interrupts are non maskable and cannot be disabled. Therefore the bits MPV and PE are not part of the Transfer Error Interrupt Enable Set/Reset (TEIRES/R) registers.

### 26.19.1.17 Transfer Error Interrupt Enable Set/Reset (TEIRES/R)

The Transfer Error Interrupt Enable Set controls the interrupt activation of interrupt line TU\_Int1. An interrupt is generated if both the interrupt flag in TEIF and the corresponding bit in TEIRES are set.

Exceptions are the memory protection violation (MPV) and the parity (PE) error, which are related to non maskable interrupts and therefore are not part of the TEIRS/R registers. Those errors have private error lines (TU\_MPV\_err and TU\_UCT\_err), which can be connected to the Vectored Interrupt Module (VIM) and/or the Error Signaling Module (ESM). Please refer to the specific device data sheet for more details about the signal hookup.

A Transfer Error Interrupt is enabled by writing '1' to TEIRES register and disabled by writing '0' to TIERER register. Writing of '0' has no effect. Reading from both addresses will result in the same value.

**Figure 26-53. Transfer Error Interrupt Enable Set (TEIRES) [offset\_TU = 78h]**

### 26.19.1.18 Trigger Transfer to System Memory Set/Reset 1/2/3/4 (TTSMS/R1-4)

The Trigger Transfer to System Memory register selects the current message buffer for a Transfer Unit State Machine transfer transaction to system memory. Four 32-bit registers reflect all possible 128 message buffers.

The bits are set by writing '1' to TTSMSx and reset by writing '1' to TTSMRx or after the transfer occurred. Writing a '0' has no effect. Reading from both addresses will result in the same value.

**Figure 26-55. Trigger Transfer to System Memory Set 1 (TTSMS1) [offset\_TU = 80h]**

LEGEND: R/W = Read/Write; R = Read only; C = Clear; S = Set; -n = value after reset

**Table 26-43. Trigger Transfer to System Memory Set 1 (TTSMS1) Field Descriptions**

| Bit  | Field        | Value | Description                                                                                                                                                                                                                                                                                                                                   |
|------|--------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | TTSMS1(31-0) |       | Trigger Transfer to System Memory Set 1. The register bits 0 to 31 correspond to message buffers 0 to 31. Each bit of the register controls the message buffer transfer to the system memory in the following manner (not that only the least significant bit of all four combined TTSM registers will currently scheduled for transmission). |
|      |              | 0     | No transfer request.                                                                                                                                                                                                                                                                                                                          |
|      |              | 1     | Transfer based on address defined in TBA                                                                                                                                                                                                                                                                                                      |

### 26.19.1.19 Trigger Transfer to Communication Controller Set/Reset 1/2/3/4 (TTCCS/R1-4)

The Trigger Transfer to Communication Controller registers select the current message buffer for a Transfer Unit State Machine transfer transaction from system memory. Four 32-bit registers reflect all possible 128 message buffers.

The bits are set by writing '1' to TTCCSx and reset by writing '1' to TTCCRx or after the transfer occurred. Writing a '0' has no effect. Reading from both addresses will result in the same value.

### 26.19.1.20 Enable Transfer on Event to System Memory Set/Reset 1-4 (ETESMS/R1-4)

The Enable Transfer on Event to System Memory Set registers enable a message buffer transfer to the system memory after a receive or transmit event. Four 32-bit registers reflect all possible 128 message buffers.

The bits are set by writing '1' to ETESMSx and reset by writing '1' to ETESMRx. Writing a '0' has no effect. Reading from both addresses will result in the same value.

**Figure 26-71. Enable Transfer on Event to System Memory Set 1 (ETESMS1) [offset\_TU = C0h]**

LEGEND: R/W = Read/Write; R = Read only; C = Clear; S = Set; -n = value after reset

**Table 26-59. Enable Transfer on Event to System Memory Set 1 Field Descriptions**

| Bit  | Field         | Value | Description                                                                                                                                                                                                 |

#### 26.19.1.21 Clear on Event to System Memory Set/Reset 1/2/3/4 (CESMS/R1-4)

The Clear on Event to System Memory registers disables an enabled transfer on event (enabled in ETESM) after a receive or transmit event. Four 32-bit registers reflect all possible 128 message buffers.

The bits are set by writing '1' to CESMSx and reset by writing '1' to CESMRx. Writing a '0' has no effect. Reading from both addresses will result in the same value.

### 26.19.1.22 Transfer to System Memory Interrupt Enable Set/Reset 1/2/3/4 (TSMIES/R1-4)

The Transfer to System Memory Interrupt Enable registers enable the interrupt generation on interrupt line TU\_Int0, after a transfer to the system memory occurred (flagged in TSMO). Four 32-bit Registers reflect all 128 MB's.

The bits are set by writing '1' to TSMIESx and reset by writing '1' to TSMIERx. Writing a '0' has no effect. Reading from both addresses will result in the same value.

**Figure 26-87. Transfer to System Memory Interrupt Enable Set 1 (TSMIES1) [offset\_TU = 100h]**

LEGEND: R/W = Read/Write; R = Read only; C = Clear; S = Set; -n = value after reset

**Table 26-75. Transfer to System Memory Interrupt Enable Set 1 (TSMIES1) Field Descriptions**

| Bit  | Field         | Value | Description                                                                                                                                                                                                                    |
|------|---------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | TSMIES1(31-0) |       | Transfer to System Memory Interrupt Enable Set 1. The register bits 0 to 31 correspond to message buffers 0 to 31. Each bit of the register enables a potential interrupt, which occurs if the corresponding TSMO1 bit is set: |
|      |               | 0     | No interrupt.                                                                                                                                                                                                                  |
|      |               | 1     | Interrupt is generated.                                                                                                                                                                                                        |

### 26.19.1.23 Transfer to Communication Controller Interrupt Enable Set/Reset 1/2/3/4 (TCCIES/R1-4)

The Transfer to Communication Controller Interrupt Enable registers enables the interrupt generation on interrupt line TU\_Int0, after a transfer to the communication controller occurred (flagged in TCCO). Four 32-bit Registers reflect all 128 MBs.

The bits are set by writing '1' to TCCIESx and reset by writing '1' to TCCIERx. Writing a '0' has no effect. Reading from both addresses will result in the same value.

**Figure 26-95. Transfer to Communication Controller Interrupt Enable Set 1 (TCCIES1)**

### 26.19.1.24 Transfer Configuration RAM (TCR)

The TCR consists of 128 entries, each 19 bit wide. The TCR is parity protected. The parity protection can be switched on/off by the 4-bit key (PEL(3-0)) in the Global Control Set/Reset (GCS/RF) registers.

### 26.19.1.25 TCR Parity Test Mode

In parity test mode (PEFT bit is set in Global Control Register (GC)) the parity information are visible and can be read or written. The corresponding TCR entry can be found by subtracting 0x200 from the TCR offset.

**Figure 26-104. Parity Information in TCR Parity Test Mode [offset\_TU\_RAM = 0200h - 03FFh]**

## 26.19.2 Communication Controller Registers

The FlexRay Communication Controller module allocates an address space of 2 Kbytes (0000h to 07FFh). The registers are organized as 32-bit registers. 8/16-bit accesses are also supported. CPU access to the message RAM is done through the input and output buffers. They buffer data to be transferred to and from the message RAM under control of the message handler, avoiding conflicts between CPU accesses and message reception / transmission. Alternatively to increase performance the Transfer Unit can be used for transferring buffer data.

The test registers located on address 0010h and 0014h are writable only under the conditions.

The assignment of the message buffers is done according to the scheme shown in [Figure 26-105](#). The number N of available message buffers depends on the payload length of the configured message buffers. The maximum number of message buffers is 128. The maximum payload length supported is 254 bytes.

The message buffers are separated into three consecutive groups; see [Figure 26-105](#):

- Static buffers - Transmit / receive buffers assigned to static segment
- Static + Dynamic buffers - Transmit / receive buffers assigned to static or dynamic segment
- FIFO - Receive FIFO

The message buffer separation configuration can be changed in DEFAULT\_CONFIG or CONFIG state only by programming register MRC.

The first group starts with message buffer 0 and consists of static message buffers only. Message buffer 0 is dedicated to hold the startup / sync frame or the single slot frame, if the node transmits one, as configured by SUCC1.TXST, SUCC1.TXSY, and SUCC1.TSM. In addition, message buffer 1 may be used for sync frame transmission in case that sync frames or single-slot frames should have different payloads on the two channels. In this case bit MRC.SPLM has to be programmed to 1 and message buffers 0 and 1 have to be configured with the key slot ID and can be (re)configured in DEFAULT\_CONFIG or CONFIG state only.

The second group consists of message buffers assigned to the static or to the dynamic segment. Message buffers belonging to this group may be reconfigured during run time from dynamic to static or vice versa depending on the state of MRC.SEC(1-0).

The message buffers belonging to the third group are concatenated to a single receive FIFO.

**Figure 26-105. Message Buffer Assignment**

|                    |                            |
|--------------------|----------------------------|
| Message Buffer 0   | ↓ Static Buffers           |
| Message Buffer 1   |                            |
| ...                | ↓ Static + Dynamic Buffers |
| Message Buffer N-1 | ↓ FIFO                     |
| Message Buffer N   |                            |

## 26.19.2.1 Special Registers

### 26.19.2.1.1 Test Register 1 (TEST1)

Test register 1 holds the control bits to configure the test modes of the FlexRay module. Write access to these bits is only possible if the WRTEEN bit is set. [Figure 26-106](#) and [Table 26-94](#) illustrate this register.

When the FlexRay module is operated in one of its test modes that requires WRTEEN to be set (RAM Test Mode, I/O Test Mode, Asynchronous Transmit Mode, and Loop Back Mode) only the selected test mode functionality is available.

**NOTE:** To return from test mode operation to regular FlexRay operation we strongly recommend to apply a hardware reset (Power on Reset or nReset) to reset all FlexRay internal state machines to their initial state.

The test functions are not available in addition to the normal operational mode functions, they change the functions of parts of the FlexRay module. Therefore normal operation as specified outside this chapter and as required by the FlexRay protocol specification and the FlexRay conformance test is not possible. Test mode functions may not be combined with each other or with FlexRay protocol functions.

**NOTE:** The FlexRay module should be kept in CONFIG state, while RAM Test Mode TMC(1-0) = 01 is enabled.

The test mode features are intended for hardware testing or for FlexRay bus analyzer tools. They are not intended to be used in FlexRay applications.

| 5-4 | TMC      | 0     | Test mode control.<br>Normal operation mode, default                                                                                                                                                                                                                                                                                                                                                                                                  |
|     |          | 1h    | RAM test mode - All RAM blocks of the FlexRay module are directly accessible by the host. This mode is intended to enable testing of the embedded RAM blocks during production testing.                                                                                                                                                                                                                                                               |
|     |          | 2h    | I/O test mode - The output pins txd1, txd2, txen1, txen2 are driven to the values defined by bits TXA, TXB, TXENA, TXENB. The values applied to the input pins rxd1, rxd2 can be read from register bits RXA, RXB                                                                                                                                                                                                                                     |
|     |          | 3h    | Unused - mapped to normal operation mode.                                                                                                                                                                                                                                                                                                                                                                                                             |
| 3-2 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                |
| 1   | ELBE     |       | External Loop Back Enable. There are two possibilities to perform a loop back test. External loop back via physical layer or internal loop back for in-system self-test (default). In case of an internal loop back pins txen1,2 are in their inactive state, pins txd1,2 are set to HIGH, pins rxd1,2 are not evaluated. Bit ELBE is evaluated only when POC is in loop back mode and test mode control is in normal operation mode TMC[1:0] = "00". |
|     |          | 0     | Internal loop back (default)                                                                                                                                                                                                                                                                                                                                                                                                                          |
|     |          | 1     | External loop back                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 0   | WRTEN    |       | Write test register enable. Enables write access to the test registers. To set the bit from 0 to 1 the test mode key has to be written as defined in Lock Register (LCK). The unlock sequence is not required when WRTEN is kept at 1 while other bits of the register are changed. The bit can be reset to 0 at any time.                                                                                                                            |
|     |          | 0     | Write access to the test register is disabled.                                                                                                                                                                                                                                                                                                                                                                                                        |
|     |          | 1     | Write access to the test register is enabled.                                                                                                                                                                                                                                                                                                                                                                                                         |

#### 26.19.2.1.1.1 Asynchronous Transmit Mode (ATM)

The asynchronous transmit mode is entered by writing 1110 to the controller host interface command vector CMD(3-0) in the SUC configuration register 1 (controller host interface command: ATM) while the communication controller is in CONFIG state and bit WRTEN in the test register 1 is set to 1. When called in any other state or when bit WRTEN is not set, CMD(3-0) will be reset to 0000 = command\_not\_accepted. POCS(5-0) in the communication controller status vector will show 00 1110 while the FlexRay module is in ATM mode.

Asynchronous transmit mode can be left by writing 0001 (controller host interface command: CONFIG) to the controller host interface command vector CMD(3-0) in the SUC configuration register 1.

In ATM mode transmission of a FlexRay frame is triggered by writing the number of the corresponding message buffer to the input buffer command request register while bit STXR in the input buffer command mask register is set to 1. In this mode wakeup, startup, and clock synchronization are bypassed, the controller host interface command SEND\_MTS results in the immediate transmission of a MTS symbol.

MTS symbols received while operating in ATM mode will set the status interrupt flags MTSA,B in the Status Interrupt Register like in monitor mode.

#### 26.19.2.1.1.2 Loop Back Mode

The loop back mode is entered by writing 1111 to the controller host interface command vector CMD(3-0) in the SUC configuration register 1 (controller host interface command: LOOP\_BACK) while the communication controller is in CONFIG state and bit WRTEN in the test register 1 is set to 1. This write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). When called in any other state or when bit WRTEN is not set, CMD(3-0) will be reset to 0000 = command\_not\_accepted. POCS(5-0) in the communication controller status vector will show 00 1101 while the FlexRay module is in loop back mode.

Loop back mode can be left by writing 0001 (controller host interface command: CONFIG) to the controller host interface command vector CMD(3-0) in the SUC configuration register 1.

The loop back mode is intended to check the modules internal data paths. Normal, time triggered operation is not possible in loop back mode.

There are two possibilities to perform a loop back test. External loop back through the physical layer (TEST1.ELBE = 1) or internal loop back for in-system self-test (TEST1.ELBE = 0). In case of an internal loop back pins txen1,2\_n are in their inactive state, pins txd1,2 are set, pins rxd1,2 are not evaluated.

When the communication controller is in loop back mode, a loop back test is started by the host writing a message to the input buffer and requesting the transmission by writing to the input buffer command request register. The message handler will transfer the message into the message RAM and then into the transient buffer of the selected channel. The channel protocol controller (PRT) will read (in 32-bit words) the message from the transmit part of the transient buffer and load it into its Rx / Tx shift register. The serial transmission is looped back into the shift register; its content is written into the receive part of the channels transient buffer before the next word is loaded.

The PRT and the message handler will then treat this transmitted message like a received message, perform an acceptance filtering on frame ID and receive channel, and store the message into the message RAM (assuming the message passed the acceptance filter, thus testing the acceptance filter logic). The loop back test ends with the host requesting this received message from the message RAM and then checking the contents of the output buffer.

Each FlexRay channel is tested separately. The FlexRay module cannot receive messages from the FlexRay bus while it is in the loop back mode.

The cycle counter value of frames used in loop back mode can be programmed by writing to the CCV(5:0) bits of the MTCCV register (writable in ATM and loop back mode only).

---

**NOTE:** In case of an odd payload the last two bytes of the looped-back payload will be right aligned (shifted by 16 bits to the right) inside the last 32-bit data word.

---

The controller host interface command SEND\_MTS results in the immediate transmission of an MTS symbol. Transmitted MTS symbols will not cause status interrupt flags MTSA,B to be set in the Status Interrupt Register. MTS symbols received while operating in loop back mode will set status interrupt flags MTSA,B in System Interrupt Register like in monitor mode. The reception of an MTS symbol can be emulated by driving the FlexRay receive pins Rx1,2 to low for the duration of the symbol in external loop back mode, or by driving the FlexRay pins Tx1,2 and TxEN1,2 to low using the TXA,B and TXENA,B of Test Register1 in internal or external loop back mode.

#### 26.19.2.1.2 Test Register 2 (TEST2)

Test register 2 holds all bits required for RAM test of the seven embedded RAM blocks of the communication controller. Write access to this register is only possible when bit WRTEN in the test register 1 is set.

Figure 26-107 and Table 26-95 illustrate this register.

**Figure 26-107. Test Register 2 (TEST2) [offset\_CC = 14h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

### Table 26-95. Test Register 2 (TEST2) Field Descriptions

| Bit   | Field    | Value | Description                                                                                                                      |
|-------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                           |
| 15    | RDPB     | 0-1   | Read parity bit. Value of parity bit read from the selected RAM location.                                                        |
| 14    | WRPB     | 0-1   | Write parity bit. Value of parity bit to be written to the selected RAM location                                                 |
| 13-7  | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                           |
| 6-4   | SSEL     |       | Segment select. To enable access to the complete message RAM (8192 byte addresses) the message RAM is segmented.                 |
|       |          | 0     | Access to RAM bytes 0000h to 03FFh enabled                                                                                       |
|       |          | 1h    | Access to RAM bytes 0400h to 07FFh enabled                                                                                       |
|       |          | 2h    | Access to RAM bytes 0800h to 0BFFh enabled                                                                                       |
|       |          | 3h    | Access to RAM bytes 0C00h to 0FFFh enabled                                                                                       |
|       |          | 4h    | Access to RAM bytes 1000h to 13FFh enabled                                                                                       |
|       |          | 5h    | Access to RAM bytes 1400h to 17FFh enabled                                                                                       |
|       |          | 6h    | Access to RAM bytes 1800h to 1BFFh enabled                                                                                       |
|       |          | 7h    | Access to RAM bytes 1C00h to 1FFFh enabled                                                                                       |
| 3     | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                           |
| 2-0   | RS       |       | RAM select. In RAM test mode the RAM blocks selected by RS(2-0) are mapped to module address 0x400 to 7FF (1024 byte addresses). |
|       |          | 0     | Input buffer RAM 1                                                                                                               |
|       |          | 1h    | Input buffer RAM 2                                                                                                               |
|       |          | 2h    | Output buffer RAM 1                                                                                                              |

### 26.19.2.1.2.1 RAM Test Mode

In RAM test mode [TMC(1-0) = 01], one of the seven RAM blocks can be selected for direct read and write access by programming RS(2-0) to the corresponding value; see [Figure 26-108](#).

For external RAM access in RAM test mode, the selected RAM block is mapped to the address range offset\_CC 400h to 7FFh, which is the address space for the input and output buffer register sets in normal operation. Hence, the functionality of the input and output buffer register sets is not available in RAM test mode.

With the available address space (offset\_CC 400h to 7FFh) in RAM test mode, 1024 bytes of RAM can be addressed for direct access. Since the length of the Message RAM exceeds the available address space, the Message RAM is segmented into segments of 1024 bytes. The segments can be selected by programming the bits SSEL(2-0) of test register 2.

**Figure 26-108. Test Mode Access to Communication Controller RAM Blocks**

### 26.19.2.1.3 Lock Register (LCK)

The lock register is write-only. Reading the register will return 00.

Figure 26-109 and Table 26-96 illustrate this register.

**Figure 26-109. Lock Register (LCK) [offset\_CC = 1Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-96. Lock Register (LCK) Field Descriptions**

| Bit   | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------|----------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 15-8  | TMK      | 0-1FFh | Test mode key. To write bit WRTE in the test register to 1, the write operation has to be directly preceded by two consecutive write accesses to the test mode key (unlock sequence). If this write sequence is interrupted by other write accesses, bit WRTE is not set to 1 and the sequence has to be repeated.<br><br>First write (LCK.TMK[7:0]): 75h = 0b0111 0101<br>Second write (LCK.TMK[7:0]): 8Ah = 0b1000 1010<br>Third write: TEST1.WRTE = 1                                                                                                                                   |
| 7-0   | CLK      | 0-FFh  | Configuration lock key. To leave CONFIG state by writing to CMD(3-0) in the SUC configuration register 1 (commands READY; MONITOR_MODE; ATM; LOOP_BACK), the write operation has to be directly preceded by two consecutive write accesses to the configuration lock key (unlock sequence). If this write sequence is interrupted by other write accesses, the communication controller remains in CONFIG state and the sequence has to be repeated.<br><br>First write (LCK.CLK[7:0]): CEh = 0b1100 1110<br>Second write (LCK.CLK[7:0]): 31h = 0b0011 0001<br>Third write (SUCC.CMD[3:0]) |

**NOTE:** In case that the Host uses 8/16-bit accesses to write the listed bit fields, the programmer has to ensure that no "dummy accesses" e.g. to the remaining register bytes / words are inserted by the compiler.

## 26.19.2.2 Interrupt Registers

### 26.19.2.2.1 Error Interrupt Register (EIR)

The flags are set when the communication controller detects one of the listed error conditions. They remain set until the host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. A reset will also clear the register.

Figure 26-110 and Table 26-97 illustrate this register.

**Figure 26-110. Error Interrupt Register (EIR) [offset\_CC = 20h]**

| Bit | Field | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----|-------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16  | WUPA  | 0<br>1 | Wakeup pattern channel A. This flag is set by the communication controller when a wakeup pattern was received on channel A.<br>No wakeup pattern on channel A<br>Wakeup pattern on channel A                                                                                                                                                                                                                                                                                                                                  |
| 15  | SDS   | 0<br>1 | Start of Dynamic Segment. This flag is set by the communication controller when the dynamic segment starts.<br>Dynamic segment not yet started<br>Dynamic segment started                                                                                                                                                                                                                                                                                                                                                     |
| 14  | MBSI  | 0<br>1 | Message buffer status interrupt. This flag is set by the communication controller if bit MBI of a dedicated receive buffer is set to 1 and when the status of that message buffer has been updated due to reception of a: <ul style="list-style-type: none"> <li>valid frame with payload</li> <li>valid frame with payload zero</li> <li>null frame</li> <li>corrupted frame or an empty slot</li> </ul> No message buffer status has been updated.<br>Message buffer status of at least one receive buffer has been updated |
| 13  | SUCS  | 0<br>1 | Startup completed successfully. This flag is set whenever a startup completed successfully and the communication controller entered NORMAL_ACTIVE state.<br>No startup completed successfully<br>Startup completed successfully                                                                                                                                                                                                                                                                                               |
| 12  | SWE   | 0<br>1 | Stop watch event. If enabled by the respective control bits located in the Stop watch register, a detected edge on external stop watch pin or a software trigger event will generate a stop watch event.<br>No stop watch event<br>Stop watch event occurred                                                                                                                                                                                                                                                                  |
| 11  | TOBC  | 0<br>1 | Transfer output buffer completed. This flag is set whenever a transfer from the message RAM to the output buffer has completed and bit OBSYS in the output buffer command request register has been reset by the message handler.<br>No transfer completed since bit was reset<br>Transfer between message RAM and output buffer completed                                                                                                                                                                                    |
| 10  | TIBC  | 0<br>1 | Transfer input buffer completed. This flag is set whenever a transfer from input buffer to the message RAM has completed and bit IBSYS in the input buffer command request register has been reset by the message handler.<br>No transfer completed since bit was reset<br>Transfer between input buffer and message RAM completed                                                                                                                                                                                            |
| 9   | TI1   | 0<br>1 | Timer interrupt 1. This flag is set whenever the conditions programmed in the timer interrupt 1 configuration register are met. A timer interrupt 1 is also signaled on pin CC_tint1.<br>No timer interrupt 1<br>Timer interrupt 1 occurred                                                                                                                                                                                                                                                                                   |
| 8   | TI0   | 0<br>1 | Timer interrupt 0. This flag is set whenever the conditions programmed in the timer interrupt 0 configuration register are met. A timer interrupt 0 is also signaled on pin CC_tint0.<br>No timer interrupt 0<br>Timer interrupt 0 occurred                                                                                                                                                                                                                                                                                   |
| 7   | NMVC  | 0<br>1 | Network management vector changed. This interrupt flag signals a change in the Network management vector visible to the host.<br>No change in the network management vector<br>Network management vector changed                                                                                                                                                                                                                                                                                                              |
| 6   | RFCL  | 0<br>1 | Receive FIFO critical level. This flag is set when the receive FIFO fill level FSR.RFFL[7:0] is equal or greater than the critical level as configured by FCL.CL[7:0].<br>Receive FIFO below critical level<br>Receive FIFO critical level reached                                                                                                                                                                                                                                                                            |

**Table 26-98. Status Interrupt Register (SIR) Field Descriptions (continued)**

| Bit | Field | Value  | Description                                                                                                                                                                                                                                                                                                                         |
|-----|-------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | RFNE  | 0<br>1 | Receive FIFO not empty. This flag is set by the communication controller when a received valid frame was stored into the empty receive FIFO. The actual state of the receive FIFO is monitored in register FSR.<br>Receive FIFO is empty<br>Receive FIFO is not empty                                                               |
| 4   | RXI   | 0<br>1 | Receive interrupt. This flag is set by the communication controller when the payload segment of a received valid frame was stored into the data section of a matching dedicated receive buffer and if bit MBI of that message buffer is set to 1.<br>No data section has been updated<br>At least one data section has been updated |
| 3   | TXI   | 0<br>1 | Transmit interrupt. This flag is set by the communication controller after successful frame transmission if bit MBI in the respective message buffer is set to 1.<br>No frame transmitted<br>At least one frame was transmitted successfully                                                                                        |
| 2   | CYCS  | 0<br>1 | Cycle start interrupt. This flag is set by the communication controller when a communication cycle starts.<br>No communication cycle started<br>Communication cycle started                                                                                                                                                         |
| 1   | CAS   | 0<br>1 | Collision avoidance symbol. This flag is set by the communication controller when a CAS was received.<br>No CAS symbol received<br>CAS symbol received                                                                                                                                                                              |
| 0   | WST   | 0<br>1 | This flag is set when WSV(2:0) in the communication controller status vector register changes to a value other than UNDEFINED.<br>Wakeup status unchanged<br>Wakeup status changed                                                                                                                                                  |

### 26.19.2.2.3 Error Interrupt Line Select (EILS)

The settings in the error interrupt line select register assigns an interrupt generated by a specific error interrupt flag to one of the two module interrupt lines (CC\_int0 or CC\_int1).

Figure 26-112 and Table 26-99 illustrate this register.

**Figure 26-112. Error Interrupt Line Select Register (EILS) [offset\_CC = 28h]**

|     |       | 0     | POC error mode changed interrupt line        |
|     |       | 1     | Interrupt assigned to interrupt line CC_int0 |

#### 26.19.2.2.4 Status Interrupt Line Select (SILS)

The settings in the status interrupt line select register assign an interrupt generated by a specific status interrupt flag to one of the two module interrupt lines (CC\_int0 or CC\_int1).

Figure 26-113 and Table 26-100 illustrate this register.

**Figure 26-113. Status Interrupt Line Select Register (SILS) [offset\_CC = 2Ch]**

[illegible]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

### Table 26-100. Status Interrupt Line Select Register (SILS) Field Descriptions

| Bit   | Field    | Value | Description                                        |
|-------|----------|-------|----------------------------------------------------|
| 31-26 | Reserved | 0     | Read returns 0. Writes have no effect.             |
| 25    | MTSBL    |       | Media access test symbol channel B interrupt line. |
|       |          | 0     | Interrupt assigned to interrupt line CC_int0       |
|       |          | 1     | Interrupt assigned to interrupt line CC_int1       |
| 24    | WUPBL    |       | Wakeup pattern channel B interrupt line.           |
|       |          | 0     | Interrupt assigned to interrupt line CC_int0       |
|       |          | 1     | Interrupt assigned to interrupt line CC_int1       |
| 23-18 | Reserved | 0     | Read returns 0. Writes have no effect.             |
| 17    | MTSAL    |       | Media access test symbol channel A interrupt line. |
|       |          | 0     | Interrupt assigned to interrupt line CC_int0       |
|       |          | 1     | Interrupt assigned to interrupt line CC_int1       |
| 16    | WUPAL    |       | Wakeup pattern channel A interrupt line.           |
|       |          | 0     | Interrupt assigned to interrupt line CC_int0       |
|       |          | 1     | Interrupt assigned to interrupt line CC_int1       |
| 15    | SDSL     |       | Start of Dynamic Segment Interrupt Line            |
|       |          | 0     | Interrupt assigned to interrupt line CC_int0       |
|       |          | 1     | Interrupt assigned to interrupt line CC_int1       |
| 14    | MBSIL    |       | Message buffer status interrupt line.              |
|       |          | 0     | Interrupt assigned to interrupt line CC_int0       |
|       |          | 1     | Interrupt assigned to interrupt line CC_int1       |
| 13    | SUCSL    |       | Startup completed Successfully interrupt line.     |
|       |          | 0     | Interrupt assigned to interrupt line CC_int0       |
|       |          | 1     | Interrupt assigned to interrupt line CC_int1       |
| 12    | SWEL     |       | Stop watch event interrupt line.                   |
|       |          | 0     | Interrupt assigned to interrupt line CC_int0       |
|       |          | 1     | Interrupt assigned to interrupt line CC_int1       |
| 11    | TOBCL    |       | Transfer output buffer completed interrupt line.   |
|       |          | 0     | Interrupt assigned to interrupt line CC_int0       |
|       |          | 1     | Interrupt assigned to interrupt line CC_int1       |
| 10    | TIBCL    |       | Transfer input buffer completed interrupt line.    |
|       |          | 0     | Interrupt assigned to interrupt line CC_int0       |
|       |          | 1     | Interrupt assigned to interrupt line CC_int1       |

**Table 26-100. Status Interrupt Line Select Register (SILS) Field Descriptions (continued)**

| Bit | Field | Value | Description                                       |
|-----|-------|-------|---------------------------------------------------|
| 9   | TI1L  | 0     | Timer interrupt 1 line.                           |
|     |       | 1     | Interrupt assigned to interrupt line CC_int0      |
| 8   | TI0L  | 0     | Interrupt assigned to interrupt line CC_int1      |
|     |       | 1     | Timer interrupt 0 line.                           |
| 7   | NMVCL | 0     | Interrupt assigned to interrupt line CC_int0      |
|     |       | 1     | Network management vector changed interrupt line. |
| 6   | RFCLL | 0     | Interrupt assigned to interrupt line CC_int0      |
|     |       | 1     | Receive FIFO full interrupt line.                 |
| 5   | RFNEL | 0     | Interrupt assigned to interrupt line CC_int0      |
|     |       | 1     | Receive FIFO not empty interrupt line.            |
| 4   | RXIL  | 0     | Interrupt assigned to interrupt line CC_int0      |
|     |       | 1     | Receive interrupt line.                           |
| 3   | TXIL  | 0     | Interrupt assigned to interrupt line CC_int0      |
|     |       | 1     | Transmit interrupt line.                          |
| 2   | CYCSL | 0     | Interrupt assigned to interrupt line CC_int0      |
|     |       | 1     | Cycle start interrupt line.                       |
| 1   | CASL  | 0     | Interrupt assigned to interrupt line CC_int0      |
|     |       | 1     | Collision Avoidance symbol interrupt line.        |
| 0   | WSTL  | 0     | Interrupt assigned to interrupt line CC_int0      |
|     |       | 1     | Wakeup status interrupt line.                     |

### 26.19.2.2.5 Error Interrupt Enable Set / Reset (EIES, EIER)

The settings in the error interrupt enable register determine which status changes in the error interrupt register will result in an interrupt. The enable bits are set by writing to address 30h and reset by writing to address 34h. Writing a 1 sets / resets the specific enable bit, a 0 has no effect.

Figure 26-114 and Table 26-101 illustrate this register.

**Figure 26-114. Error Interrupt Enable Set/Reset Register (EIES, EIER) [offset\_CC = 30h-34h]**

#### 26.19.2.2.6 Status Interrupt Enable Set / Reset Register (SIES, SIER)

The settings in the status interrupt enable register determine which status changes in the status interrupt register will result in an interrupt. The enable bits are set by writing to address 38h and reset by writing to address 3Ch. Writing a 1 sets / resets the specific enable bit, a 0 has no effect.

Figure 26-115 and Table 26-102 illustrate this register.

**Figure 26-115. Status Interrupt Enable Set/Reset Register (SIES, SIER) [offset\_CC = 38h-3Ch]**

[illegible]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

### 26.19.2.2.7 Interrupt Line Enable Register (ILE)

Each of the two interrupt lines (CC\_int0, CC\_int1) can be enabled / disabled separately by programming bit EINT0 and EINT1.

Figure 26-116 and Table 26-103 illustrate this register.

**Figure 26-116. Interrupt Line Enable Register (ILE) [offset\_CC = 40h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-103. Interrupt Line Enable Register (ILE) Field Descriptions**

| Bit  | Field    | Value | Description                                         |
|------|----------|-------|-----------------------------------------------------|
| 31-2 | Reserved | 0     | Read returns 0. Writes have no effect.              |
| 1-0  | EINT     | 0-3h  | Enable interrupt line (1-0).                        |
|      |          | 0     | Interrupt line CC_int1 and CC_int0 disabled         |
|      |          | 1h    | Interrupt line CC_int1 disabled and CC_int0 enabled |
|      |          | 2h    | Interrupt line CC_int1 enabled and CC_int0 disabled |
|      |          | 3h    | Interrupt line CC_int1 and CC_int0 enabled          |

#### 26.19.2.2.8 Timer 0 Configuration Register (T0C)

This absolute timer specifies, in terms of cycle count and macrotick, the point in time when the timer 0 interrupt occurs. The timer 0 interrupt generates a non maskable interrupt signal on CC\_tint0.

Timer 0 can be activated as long as the POC is either in NORMAL\_ACTIVE state or in NORMAL\_PASSIVE state. Timer 0 is deactivated when leaving NORMAL\_ACTIVE state or NORMAL\_PASSIVE state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by writing bit T0RC to 0.

Figure 26-117 and Table 26-104 illustrate this register.

**Figure 26-117. Timer 0 Configuration Register (T0C) [offset CC = 44h]**

#### 26.19.2.2.9 Timer 1 Configuration Register (T1C)

This relative timer generates an interrupt on the non maskable interrupt signal CC\_tint1 after the specified number of macroticks has expired.

Timer 1 can be activated as long as the POC is either in NORMAL\_ACTIVE state or in NORMAL\_PASSIVE state. Timer 1 is deactivated when leaving NORMAL\_ACTIVE state or NORMAL\_PASSIVE state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by writing bit T1RC to 0.

Figure 26-118 and Table 26-105 illustrate this register.

**Figure 26-118. Timer 1 Configuration Register (T1C) [offset\_CC = 48h]**

#### 26.19.2.2.10 Stop Watch Register 1 Register (STPW1)

The stop watch is activated by an interrupt event (CC\_int0 or CC\_int1), by writing bit SSWT to 1, or by an external event.

With the macrotick counter increment following next to the stop watch activation the actual cycle counter and macrotick value is stored in the stop watch register 1 (stop watch event) and the slot counter values for channel A and channel B are stored in stop watch register 2.

Figure 26-119 and Table 26-106 illustrate this register.

**Figure 26-119. Stop Watch Register 1 (STPW1) [offset\_CC = 4Ch]**

[illegible]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

### Table 26-106. Stop Watch Register 1 (STPW1) Field Descriptions

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                  |

Enables stop watch trigger event from external pin, if ESWT = '1'.<br>External trigger disabled<br>Stop watch activated by external trigger                                                                                                                                                     |
| 3     | SSWT     | 0<br>1  | Software stop watch trigger. When the host writes this bit to 1 the stop watch is activated. After the actual cycle counter and macrotick value are stored in the stop watch register this bit is reset to 0. The bit is only writable while ESWT = 0.<br>Software trigger reset<br>Stop watch activated by software trigger |
| 2     | EDGE     | 0<br>1  | Stop watch trigger edge select.<br>Falling edge<br>Rising edge                                                                                                                                                                                                                                                               |
| 1     | SWMS     | 0<br>1  | Stop watch mode select.<br>Single-shot mode<br>Continuous mode                                                                                                                                                                                                                                                               |
| 0     | ESWT     | 0<br>1  | External stop watch trigger. If enabled an external event activates the stop watch. In single-shot mode this bit is reset to 0 after the stop watch event occurred.<br>External stop watch trigger disabled<br>External stop watch trigger enabled                                                                           |

**NOTE:** Bits ESWT and SSWT cannot be set to '1' simultaneously. In this case the write access to the register is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

**NOTE:** The availability of an external stop watch pin is device dependant. Please refer to the device data sheet for details.

### 26.19.2.2.11 Stop Watch Register 2 Register (STPW2)

Figure 26-120 and Table 26-107 illustrate this register.

**Figure 26-120. Stop Watch Register 2 (STPW2) [offset\_CC = 50h]**

### 26.19.2.3 Control Registers

This section describes the registers provided by the communication controller to allow the host to control the operation of the communication controller. The FlexRay protocol specification requires the host to write application configuration data in CONFIG state only.

**NOTE:** Please be aware that the configuration registers are not locked for writing in DEFAULT\_CONFIG state.

The configuration data is reset when DEFAULT\_CONFIG state is entered from hardware reset. To change POC state from DEFAULT\_CONFIG to CONFIG state the host has to apply the controller host interface command CONFIG. If the host wants the communication controller to leave CONFIG state, the host has to proceed as described in Lock Register (LCK).

**NOTE:** All bits marked with an asterisk (\*) can be updated in DEFAULT\_CONFIG or CONFIG state only.

#### 26.19.2.3.1 SUC Configuration Register 1 (SUCC1)

The communication controller accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Figure 26-121 and Table 26-108 illustrate this register.

**Figure 26-121. SUC Configuration Register 1 (SUCC1) [offset\_CC = 80h]**

**Table 26-108. SUC Configuration Register 1 (SUCC1) Field Descriptions (continued)**

| Bit | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----|-------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3-0 | CMD   |       | The controller host interface command vector. The host may write any controller host interface command at any time, but certain commands are enabled only in certain POC states. If a command is not enabled, it will not be executed, the controller host interface command vector CMD(3-0) will be reset to 0000 = command_not_accepted, and flag CNA in the error interrupt register will be set to 1. In case the previous controller host interface (CHI) command has not yet completed, EIR.CCL is set to '1' together with EIR.CNA; the CHI command needs to be repeated. Except for HALT state, a POC state change command applied while the communication controller is already in the requested POC state neither causes a state change nor will EIR.CNA be set. |
|     |       | 0     | command_not_accepted                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|     |       | Dh-Eh | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|     |       | Fh    | LOOPBACK MODE                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

Controller Host Interface Command Vector:

The following gives more information about the controller host interface commands.

- Reading CMD(3-0) shows whether the last controller host interface command was accepted.
- The actual POC state is monitored by POCS(5-0) in the communication controller status vector
- In most cases the Host must check SUCC1.PBSY before writing a new CHI command.

#### ***command\_not\_accepted***

CMD(3-0) is reset to 0000 due to one of the following conditions:

- Illegal command applied by the host
- Host applied command to leave CONFIG state without preceding configuration lock key
- Host applied new command while execution of the previous host command has not completed
- Host writes command\_not\_accepted

When CMD(3-0) is reset to 0000 due to an unaccepted command, bit CNA in the error interrupt register is set, and - if enabled - an interrupt is generated. Commands which are not accepted are not executed.

#### ***CONFIG***

Go to POC state CONFIG when called in POC states DEFAULT\_CONFIG, READY, or in MONITOR\_MODE. When called in HALT state the communication controller transits to POC state DEFAULT\_CONFIG. When called in any other state, CMD(3-0) will be reset to 0000 = command\_not\_accepted.

#### ***READY***

Go to POC state READY when called in POC states CONFIG, NORMAL\_ACTIVE, NORMAL\_PASSIVE, STARTUP, or WAKEUP. When called in any other state, CMD(3-0) will be reset to 0000 = command\_not\_accepted.

## **WAKEUP**

Go to POC state WAKEUP when called in POC state READY. When called in any other state, CMD(3-0) will be reset to 0000 = command\_not\_accepted.

## **RUN**

Go to POC state STARTUP when called in POC state READY. When called in any other state, CMD(3-0) will be reset to 0000 = command\_not\_accepted.

## **ALL\_SLOTS**

Leave single slot mode after successful startup / integration at the next end of cycle when called in POC states NORMAL\_ACTIVE or NORMAL\_PASSIVE. When called in any other state, CMD(3-0) will be reset to 0000 = command\_not\_accepted.

## **HALT**

Set the Halt request HRQ bit in the communication controller status vector register and go to POC state HALT at the next end of cycle when called in POC states NORMAL\_ACTIVE or NORMAL\_PASSIVE. When called in any other state, CMD(3-0) will be reset to 0000 = command\_not\_accepted.

## **FREEZE**

Go to POC state HALT immediately and set the Freeze status Indicator FSI bit in the communication controller status vector register. Can be called from any state.

## **SEND\_MTS**

Send single MTS symbol during the symbol window of the following cycle on the channel configured by MTSA, MTSB, when called in POC state NORMAL\_ACTIVE. When called in any other state, CMD(3-0) will be reset to 0000 = command\_not\_accepted.

## **ALLOW\_COLDSTART**

Reset status flags FSI, HRQ, CSNI

The command resets bit CSI in the CCSV register to enable coldstarting of the node when called in any POC state except DEFAULT\_CONFIG, CONFIG or HALT. When called in these states, CMD(3-0) will be reset to 0000 = command\_not\_accepted.

### **RESET\_STATUS\_INDICATORS**

, and CSAI in the communication controller status vector register.

## **CLEAR\_RAMs**

Sets bit CRAM in the message handler status register when called in DEFAULT\_CONFIG or CONFIG state. When called in any other state, CMD(3-0) will be reset to 0000 = command\_not\_accepted. Bit CRAM is also set when the communication controller leaves hardware reset. By setting bit CRAM all internal RAM blocks are initialized to zero. During the initialization of the RAMs, PBSY will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR\_RAMs.

The initialization of the Communication Controller internal RAM blocks takes 2048 VBUS clock cycles. There should be no host access to IBF or OBF during initialization of the internal RAM blocks after hardware reset or after assertion of controller host interface command CLEAR\_RAMs. Before asserting controller host interface command CLEAR\_RAMs the host should be aware that no transfer between message RAM and IBF / OBF or the transient buffer RAMs is ongoing. This command also resets the message buffer status registers (MHDS, TXRQ1/2/3/4, NDAT1/2/3/4, MBSC1/2/3/4).

---

**NOTE:** All accepted commands with exception of CLEAR\_RAMs and SEND\_MTS will cause a change of the POC state in the VBUS clock domain after at most 8 cycles of the slower of the two clocks VBUS clock and 80MHz sample clock coming from the PLL. It is assumed that POC was not busy when the command was applied and that no POC state change was forced by bus activity in that time frame. Reading register Communication Controller Status Vector (CCSV) will show data that is additionally delayed by synchronization from sample clock to VBUS clock domain and by the CPU interface. The maximum additional delay is 12 cycles of the slower of the two clocks VBUS clock and sample clock.

---

## MONITOR\_MODE

Enter MONITOR\_MODE when called in POC state CONFIG. In this mode the communication controller is able to receive FlexRay frames and CAS / MTS symbols. It is also able to detect coding errors. The temporal integrity of received frames is not checked. This mode can be used for debugging purposes, e.g. in case that the startup of a FlexRay network fails. When called in any other state, CMD(3-0) will be reset to 0000 = command\_not\_accepted.

### 26.19.2.3.2 SUC Configuration Register 2 (SUCC2)

The communication controller accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Figure 26-122 and Table 26-109 illustrate this register.

**Figure 26-122. SUC Configuration Register 2 (SUCC2) [offset\_CC = 84h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; \*These bits can be updated in DEFAULT\_CONFIG or CONFIG state only.

**Table 26-109. SUC Configuration Register 2 (SUCC2) Field Descriptions**

| Bit   | Field     | Value                | Description                                                                                                                                                                                                                                                       |
|-------|-----------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-28 | Reserved. | 0                    | Reads return 0. Writes have no effect.                                                                                                                                                                                                                            |
| 27-24 | LTN       | 2-Fh                 | Listen timeout noise. Configures the upper limit for the startup and wakeup listen timeout in the presence of noise. Must be identical in all nodes of a cluster.<br>The wakeup / startup noise timeout is calculated as follows: $LT[20:0] \cdot (LTN[3:0] + 1)$ |
| 23-21 | Reserved. | 0                    | Reads return 0. Writes have no effect.                                                                                                                                                                                                                            |
| 20-0  | LT        | 504h-139706h $\mu$ T | Listen timeout. Configures the upper limit of the startup and wakeup listen timeout.                                                                                                                                                                              |

### 26.19.2.3.3 SUC Configuration Register 3 (SUCC3)

The communication controller accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Figure 26-123 and Table 26-110 illustrate this register.

**Figure 26-123. SUC Configuration Register 3 (SUCC3) [offset\_CC = 88h]**

LEGEND: R/W = Read/Write; R = Read only; D = Device-specific reset value; -n = value after reset; \*These bits can be updated in DEFAULT\_CONFIG or CONFIG state only

**Table 26-110. SUC Configuration Register 3 (SUCC3) Field Descriptions**

| Bit  | Field     | Value | Description                                                                                                                                                                                                                                                                                                                                                      |
|------|-----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved. | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                           |
| 7-4  | WCF       | 1-Fh  | Maximum without clock correction fatal. These bits define the number of consecutive even/odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE or NORMAL_PASSIVE state. These must be identical in all nodes of a cluster.<br><br><b>Note: The transition to HALT state is prevented if SUCC1.HCSE is not set.</b> |
| 3-0  | WCP       | 1-Fh  | Maximum without clock correction passive. These bits define the number of consecutive even/odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE to NORMAL_PASSIVE to HALT state. These must be identical in all nodes of a cluster.                                                                               |

### 26.19.2.3.4 NEM Configuration Register (NEMC)

The communication controller accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Figure 26-124 and Table 26-111 illustrate this register.

**Figure 26-124. NEM Configuration Register (NEMC) [offset\_CC = 8Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; \*These bits can be updated in DEFAULT\_CONFIG or CONFIG state only

**Table 26-111. NEM Configuration Register (NEMC) Field Descriptions**

| Bit  | Field     | Value      | Description                                                                                                                                                          |
|------|-----------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-7 | Reserved. | 0          | Reads return 0. Writes have no effect.                                                                                                                               |
| 6-0  | NML       | 0-Ch bytes | Network management vector length (in bytes).<br>These bits configure the length of the NM vector. The configured length must be identical in all nodes of a cluster. |

### 26.19.2.3.5 PRT Configuration Register 1 (PRTC1)

The communication controller accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Figure 26-125 and Table 26-112 illustrate this register.

**Figure 26-125. PRT Configuration Register 1 (PRTC1) [offset\_CC = 90h]**

|        |  |  |  |  |       |  |  |  |  |      |  |  |  |  |         |  |  |  |  |         |  |  |  |  |        |  |  |  |  |   |  |  |  |  |   |  |  |  |  |   |  |  |  |  |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; \*These bits can be updated in DEFAULT\_CONFIG or CONFIG state only

**Table 26-112. PRT Configuration Register 1 (PRTC1) Field Descriptions**

| Bit   | Field    | Value             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------|----------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-26 | RWP      | 2h-3Fh            | Repetition of transmission wakeup pattern. These bits configure the number of repetitions (sequences) of the transmission wakeup symbol.                                                                                                                                                                                                                                                                                                                                                             |
| 25    | Reserved | 0                 | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 24-16 | RXW      | 4Ch-12Dh          | Wakeup symbol receive window length. Configures the number of bit times used by the node to test the duration of the received wakeup pattern. Must be identical in all nodes of a cluster.                                                                                                                                                                                                                                                                                                           |
| 15-14 | BRP      | 0<br>1h<br>2h, 3h | Baud rate prescaler. These bits configure the baud rate on the FlexRay bus. The baud rates listed below are valid with a sample clock of 80 MHz. One bit time always consists of 8 samples independent of the configured baud rate.<br>10 Mbit/s (Sample Clock Period = 12.5ns; 1 $\mu$ T = 25ns; Samples per $\mu$ T = 2)<br>5 Mbit/s (Sample Clock Period = 25ns; 1 $\mu$ T = 25ns; Samples per $\mu$ T = 1)<br>2.5 Mbit/s (Sample Clock Period = 50ns; 1 $\mu$ T = 50ns; Samples per $\mu$ T = 1) |
| 13-12 | SPP      | 0, 3h<br>1h<br>2h | Strobe Point Position. Defines the sample count value for strobing. The strobed bit value is set to the voted value when the sample count is incremented to the value configured by SPP[1:0].<br><b>Note: The current revision 2.1 of the FlexRay protocol requires that SPP[1:0] = "00". The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.</b><br>Sample 5 (default)<br>Sample 4<br>Sample 6                                                  |
| 11    | Reserved | 0                 | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 10-4  | CASM     | 43h-63h bit times | Collision avoidance symbol max (in bit times). These bits configure the upper limit of the acceptance window for a collision avoidance symbol (CAS). CASM6 is always '1'.                                                                                                                                                                                                                                                                                                                            |
| 3-0   | TSST     | 3h-Fh bit times   | Transmission start sequence transmitter (in bit times). These bits configure the duration of the transmission start sequence (TSS) in terms of bit times (1 bit time = 4 $\mu$ T = 100ns @ 10Mbps). Must be identical in all nodes of a cluster.                                                                                                                                                                                                                                                     |

### 26.19.2.3.6 PRT Configuration Register 2 (PRTC2)

The communication controller accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Figure 26-126 and Table 26-113 illustrate this register.

**Figure 26-126. PRT Configuration Register 2 (PRTC2) [offset\_CC = 94h]**

|          |        |    |    |    |         |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; \*These bits can be updated in DEFAULT\_CONFIG or CONFIG state only

**Table 26-113. PRT Configuration Register 2 (PRTC2) Field Descriptions**

| Bit   | Field    | Value             | Description                                                                                                                                                                                                                 |
|-------|----------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-30 | Reserved | 0                 | Read returns 0. Writes have no effect.                                                                                                                                                                                      |
| 29-24 | TXL      | Fh-3Ch bit times  | Wakeup symbol transmit low (in bit times). These bits configure the active low phase of the wakeup symbol. The duration must be identical in all nodes of a cluster.                                                        |
| 23-16 | TXI      | 2Dh-B4h bit times | Wakeup symbol transmit idle (in bit times). These bits configure the number of bit times used by the node to transmit the idle phase of the wakeup symbol. Durations must be identical in all nodes of a cluster.           |
| 15-14 | Reserved | 0                 | Read returns 0. Writes have no effect.                                                                                                                                                                                      |
| 13-8  | RXL      | Ah-37h bit times  | Wakeup symbol receive low (in bit times). These bits configure the number of bit times used by the node to test the duration of the low phase of the received wakeup symbol. Must be identical in all nodes of a cluster.   |
| 7-6   | Reserved | 0                 | Read returns 0. Writes have no effect.                                                                                                                                                                                      |
| 5-0   | RXI      | Eh-37h bit times  | Wakeup symbol receive idle (in bit times). These bits configure the number of bit times used by the node to test the duration of the idle phase of the received wakeup symbol. Must be identical in all nodes of a cluster. |

### 26.19.2.3.7 MHD Configuration Register (MHDC)

The communication controller accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Figure 26-127 and Table 26-114 illustrate this register.

**Figure 26-127. MHD Configuration Register (MHDC) [offset\_CC = 98h]**

|          |    |        |       |
|----------|----|--------|-------|

| R-0      |    | R/W-2h |       |
| 15       | 7  | 6      | 0     |
| Reserved |    |        | SFDL* |
| R-0      |    |        | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; \*These bits can be updated in DEFAULT\_CONFIG or CONFIG state only

**Table 26-114. MHD Configuration Register (MHDC) Field Descriptions**

| Bit   | Field    | Value             | Description                                                                                                                                                                                                                                              |
|-------|----------|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-29 | Reserved | 0                 | Read returns 0. Writes have no effect.                                                                                                                                                                                                                   |
| 28-16 | SLT      | 0-1F2Dh minislots | Start of latest transmit (in minislots). These bits configure the maximum minislot value allowed before inhibiting new frame transmissions in the Dynamic Segment of the cycle. There is no transmission in dynamic segment if SLT[12:0] is set to zero. |
| 15-8  | Reserved | 0                 | Read returns 0. Writes have no effect.                                                                                                                                                                                                                   |
| 7-0   | SFDL     | 0-7Fh             | Static frame data length. These bits configure the cluster-wide payload length for all frames sent in the static segment in double bytes. The payload length must be identical in all nodes of a cluster.                                                |

### 26.19.2.3.8 GTU Configuration Register 1 (GTUC1)

The communication controller accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Figure 26-128 and Table 26-115 illustrate this register.

**Figure 26-128. GTU Configuration Register 1 (GTUC1) [offset\_CC = A0h]**

|           |    |       |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; \*These bits can be updated in DEFAULT\_CONFIG or CONFIG state only

**Table 26-115. GTU Configuration Register 1 (GTUC1) Field Descriptions**

| Bit   | Field     | Value               | Description                                                                                                         |
|-------|-----------|---------------------|---------------------------------------------------------------------------------------------------------------------|
| 31-20 | Reserved. | 0                   | Reads return 0. Writes have no effect.                                                                              |
| 19-0  | UT        | 280h-9C400h $\mu$ T | Microtick per cycle (in microticks).<br>These bits configure the duration of the communication cycle in microticks. |

### 26.19.2.3.9 GTU Configuration Register 2 (GTUC2)

The communication controller accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Figure 26-129 and Table 26-116 illustrate this register.

**Figure 26-129. GTU Configuration Register 2 (GTUC2) [offset\_CC = A4h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; \*These bits can be updated in DEFAULT\_CONFIG or CONFIG state only

**Table 26-116. GTU Configuration Register 2 (GTUC2) Field Descriptions**

| Bit   | Field    | Value        | Description                                                                                                                                                                                            |
|-------|----------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-20 | Reserved | 0            | Read returns 0. Writes have no effect.                                                                                                                                                                 |
| 19-16 | SNM      | 2h-Fh frames | Sync node max (in frames). These bits configure the maximum number of frames within a cluster with sync frame indicator bit SYN set. The number of frames must be identical in all nodes of a cluster. |
| 15-14 | Reserved | 0            | Read returns 0. Writes have no effect.                                                                                                                                                                 |
| 13-0  | MPC      | Ah-3E80h MT  | Macrotick per cycle (in macroticks). These bits configure the duration of one communication cycle in macroticks. The cycle length must be identical in all nodes of a cluster.                         |

### 26.19.2.3.10 GTU Configuration Register 3 (GTUC3)

The communication controller accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Figure 26-130 and Table 26-117 illustrate this register.

**Figure 26-130. GTU Configuration Register 3 (GTUC3) [offset\_CC = A8h]**

|       |        |      |        |    |    |

| R/W-0 | R/W-0  |      |        |    |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; \*These bits can be updated in DEFAULT\_CONFIG or CONFIG state only.

**Table 26-117. GTU Configuration Register 3 (GTUC3) Field Descriptions**

| Bit   | Field    | Value         | Description                                                                                                                                                                                                                                                                                          |
|-------|----------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | Reserved | 0             | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                               |
| 30-24 | MIOB     | 2h-48h MT     | Macrotick initial offset channel B (in macroticks). These bits configure the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration. Must be identical in all nodes of a cluster. |
| 23    | Reserved | 0             | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                               |
| 22-16 | MIOA     | 2h-48h MT     | Macrotick initial offset channel A (in macroticks). These bits configure the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration. Must be identical in all nodes of a cluster. |
| 15-8  | UIOB     | 0-F0h $\mu$ T | Microtick initial offset channel B (in microticks). These bits configure the number of microticks between the actual time reference point on channel B and the subsequent macrotick boundary of the secondary time reference point. The parameter has to be set for each channel independently.      |
| 7-0   | UIOA     | 0-F0h $\mu$ T | Microtick initial offset channel A (in microticks). These bits configure the number of microticks between the actual time reference point on channel A and the subsequent macrotick boundary of the secondary time reference point. The parameter has to be set for each channel independently.      |

### 26.19.2.3.11 GTU Configuration Register 4 (GTUC4)

The communication controller accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only. [Figure 26-131](#) and [Table 26-118](#) illustrate this register.

**Figure 26-131. GTU Configuration Register 4 (GTUC4) [offset\_CC = ACh]**

|          |    |        |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; \*These bits can be updated in DEFAULT\_CONFIG or CONFIG state only

**Table 26-118. GTU Configuration Register 4 (GTUC4) Field Descriptions**

| Bit   | Field    | Value       | Description                                                                                                                                                                                                                                                                     |
|-------|----------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-30 | Reserved | 0           | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                          |
| 29-16 | OCS      | 8h-3E7Eh MT | Offset correction start (in macroticks). These bits determine the start of the offset correction within the NIT phase, calculated from start of cycle. Must be identical in all nodes of a cluster.                                                                             |
| 15-14 | Reserved | 0           | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                          |
| 13-0  | NIT      | 7h-3E7Dh MT | Network idle time start (in macroticks). These bits configure the starting point of the network idle time (NIT) at the end of the communication cycle expressed in terms of macroticks from the beginning of the cycle. The number must be identical in all nodes of a cluster. |

### 26.19.2.3.12 GTU Configuration Register 5 (GTUC5)

The communication controller accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only. [Figure 26-132](#) and [Table 26-119](#) illustrate this register.

**Figure 26-132. GTU Configuration Register 5 (GTUC5) [offset\_CC = B0h]**

|        |    |          |    |       |    |

| R/W-0  |    | R/W-0    |    |       |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; \*These bits can be updated in DEFAULT\_CONFIG or CONFIG state only

**Table 26-119. GTU Configuration Register 5 (GTUC5) Field Descriptions**

| Bit   | Field     | Value          | Description                                                                                                                                                                                                                                                                                        |
|-------|-----------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | DEC       | Eh-8Fh $\mu$ T | Decoding correction (in microticks). These bits configure the decoding correction value used to determine the primary time reference point.                                                                                                                                                        |
| 23-21 | Reserved. | 0              | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                             |
| 20-16 | CDD       | 0-14h $\mu$ T  | Cluster drift damping (in microticks). These bits configure the cluster drift damping value used in clock synchronization to minimize accumulation of rounding errors.                                                                                                                             |
| 15-8  | DCB       | 0-C8h $\mu$ T  | Delay compensation channel B (in microticks). These bits are used to compensate for reception delays on the indicated channel. This compensates propagation delays for microticks in the range of 0.0125 to 0.05s. In practice, the minimum propagation delay of all sync nodes should be applied. |
| 7-0   | DCA       | 0-C8h $\mu$ T  | Delay compensation channel A (in microticks). These bits are used to compensate for reception delays on the indicated channel. This compensates propagation delays for microticks in the range of 0.0125 to 0.05s. In practice, the minimum propagation delay of all sync nodes should be applied. |

### 26.19.2.3.13 GTU Configuration Register 6 (GTUC6)

The communication controller accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Figure 26-133 and Table 26-120 illustrate this register.

**Figure 26-133. GTU Configuration Register 6 (GTUC6) [offset\_CC = B4h]**

|          |    |        |    |
|----------|----|--------|----|

## 26.19.2.4 Status Registers

During 8/16-bit accesses to status variables coded with more than 8/16-bit, the variable might be updated by the communication controller between two accesses (non-atomic read accesses). All internal counters and the communication controller status flags are reset when the communication controller transits from CONFIG to READY state.

### 26.19.2.4.1 Communication Controller Status Vector (CCSV)

Figure 26-139 and Table 26-126 illustrate this register.

**Figure 26-139. Communication Controller Status Vector Register (CCSV) [offset\_CC = 100h]**

|          |     |      |      |          |     |     |     |     |     |    |      |     |

| 31-30 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                         |
| 29-24 | PSL      |       | POC Status Log. Status of POCS[5:0] immediately before entering HALT state. Set when entering HALT state. Set to HALT when FREEZE command is applied during HALT state and FSI is not already set i.e. the HALT state was not reached by FREEZE command. Reset to "0" when leaving HALT state. |
| 23-19 | RCA      | 0-1Fh | Remaining coldstart attempts. Indicates the number of remaining coldstart attempts. The maximum number of coldstart attempts is configured by CSA(4-0) in the SUC configuration register 1.                                                                                                    |
| 18-16 | WSV      |       | Wakeup status. Indicates the status of the current wakeup attempt. Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to EFAULT_CONFIG state.                                                                                                                             |
|       |          | 0     | UNDEFINED. No wakeup attempt since CONFIG state was left.                                                                                                                                                                                                                                      |
|       |          | 1h    | RECEIVED_HEADER. Set when the communication controller finishes wakeup due to the reception of a frame header without coding violation on either channel in WAKEUP_LISTEN or WAKEUP_DETECT state.                                                                                              |
|       |          | 2h    | RECEIVED_WUP. Set when the communication controller finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in WAKEUP_LISTEN or WAKEUP_DETECT state.                                                                                                   |
|       |          | 3h    | COLLISION_HEADER. Set when the communication controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid header on either channel.                                                                                                             |
|       |          | 4h    | COLLISION_WUP. Set when the communication controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel.                                                                                         |
|       |          | 5h    | COLLISION_UNKNOWN. Set when the communication controller stops wakeup by leaving WAKEUP_DETECT state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid frame header.                                                                                    |
|       |          | 6h    | TRANSMITTED. Set when the communication controller has successfully completed the transmission of the wakeup pattern.                                                                                                                                                                          |

Indicates the actual slot mode of the POC in states READY, WAKEUP, STARTUP, NORMAL_ACTIVE, and NORMAL_PASSIVE. Default is SINGLE. Changes to ALL, depending on SUCC1.TSM. In NORMAL_ACTIVE or NORMAL_PASSIVE state the CHI command ALL_SLOTS will change the slot mode from SINGLE over ALL_PENDING to ALL. Set to SINGLE in all other states. |
| 7     | HRQ      | 0-1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Halt request. Indicates that a request from the Host has been received to halt the POC at the end of the communication cycle. Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or when entering READY state.                                                                                               |
| 6     | FSI      | 0-1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Freeze status indicator. Indicates that the POC has entered the HALT state due to CHI command FREEZE or due to an error condition requiring an immediate POC halt. Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state.                                                                                       |

**NOTE:** CHI command RESET\_STATUS\_INDICATORS (SUCC1.CMD[3:0] = "Ah") resets flags FSI, HRQ, CSNI, CSAI, the slot mode SLM[1:0], and the wakeup status WSV[2:0]

#### 26.19.2.4.2 Communication Controller Error Vector (CCEV)

Reset by CHI command RESET\_STATUS\_INDICATORS or by transition from HALT to DEFAULT\_CONFIG state or when entering READY state.

Figure 26-140 and Table 26-127 illustrate this register.

**Figure 26-140. Communication Controller Error Vector Register (CCEV) [offset\_CC = 104h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-127. Communication Controller Error Vector Register (CCEV) Field Descriptions**

| Bit   | Field    | Value                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| 21-16 | CCV      | 0-3Fh   | Cycle counter value. Current cycle counter value. The value is incremented by the communication controller at the start of a communication cycle.   |
| 15-14 | Reserved | 0       | Read returns 0. Writes have no effect.                                                                                                              |
| 13-0  | MTV      | 0-3E80h | Macrotick value. Current macrotick value. The value is incremented by the communication controller and reset at the start of a communication cycle. |

### 26.19.2.4.5 Rate Correction Value (RCV)

This register is reset when the Communication Controller leaves CONFIG state or enters STARTUP state. [Figure 26-143](#) and [Table 26-130](#) illustrate this register.

**Figure 26-143. Rate Correction Value Register (RCV) [offset\_CC = 118h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-130. Rate Correction Value Register (RCV) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                 |
|-------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-12 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                      |
| 11-0  | RCV      |       | Rate correction value (in microticks). Rate correction value (two's complement). Calculated internal rate correction value before limitation. If the RCV value exceeds the limits defined by GTUC10.MRC[10:0], flag SFS.RCLR is set to '1'. |

**NOTE:** The external rate correction value is added to the limited rate correction value.

### 26.19.2.4.6 Offset Correction Value (OCV)

[Figure 26-144](#) and [Table 26-131](#) illustrate this register.

**Figure 26-144. Offset Correction Value Register (OCV) [offset\_CC = 11Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-131. Offset Correction Value Register (OCV) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                        |
|-------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-20 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                             |
| 19-0  | OCV      |       | Offset correction value (in microticks). Offset correction value (two's complement). Calculated internal offset correction value before limitation. If the OCV value exceeds the limits defined by GTUC10.MOC[13:0], flag SFS.OCCLR is set to '1'. |

**NOTE:** The external offset correction value is added to the limited offset correction value.

#### 26.19.2.4.7 Sync Frame Status (SFS)

This register is reset when the Communication Controller leaves CONFIG state or enters STARTUP state. [Figure 26-145](#) and [Table 26-132](#) illustrate this register.

**Figure 26-145. Sync Frame Status Register (SFS) [offset\_CC = 120h]**

### Table 26-132. Sync Frame Status Register (SFS) Field Descriptions

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                         |
|-------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-20 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                              |
| 19    | RCLR     |       | Rate correction limit reached. The Rate Correction Limit Reached flag signals to the Host, that the rate correction value has exceeded its limit as defined by GTUC10.MRC[10:0]. The flag is updated by the communication controller at start of offset correction phase.                                                           |
|       |          | 0     | Rate correction below limit                                                                                                                                                                                                                                                                                                         |
|       |          | 1     | Rate correction limit reached                                                                                                                                                                                                                                                                                                       |
| 18    | MRCS     |       | Missing rate correction signal. The missing rate correction signal signals to the host that no rate correction can be performed because no pairs of even/odd sync frames were received. The flag is updated by the communication controller at start of offset correction phase.                                                    |
|       |          | 0     | Rate correction signal valid                                                                                                                                                                                                                                                                                                        |
|       |          | 1     | Missing rate correction signal                                                                                                                                                                                                                                                                                                      |
| 17    | OCLR     |       | Offset correction limit reached. The offset correction limit reached flag signals to the host that the offset correction value has reached its limit as defined by GTUC10.MOC[13:0]. The flag is updated by the communication controller at start of offset correction phase.                                                       |
|       |          | 0     | Offset correction below limit                                                                                                                                                                                                                                                                                                       |
|       |          | 1     | Offset correction limit reached                                                                                                                                                                                                                                                                                                     |
| 16    | MOCS     |       | Missing offset correction signal. The missing offset correction signal signals to the host that no rate correction can be performed because no pairs of even / odd sync frames were received. The flag is updated by the communication controller at start of offset correction phase.                                              |
|       |          | 0     | Offset correction signal valid                                                                                                                                                                                                                                                                                                      |
|       |          | 1     | Missing offset correction signal                                                                                                                                                                                                                                                                                                    |
| 15-12 | VSBO     | 0-Fh  | Valid sync frames channel B, odd communication cycle. Holds the number of valid sync frames received on channel B in the odd communication cycle. If transmission of sync frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each odd communication cycle.                     |
| 11-8  | VSBE     | 0-Fh  | Valid synch frames channel B, even communication cycle. Holds the number of valid sync frames received and transmitted on channel B in the even communication cycle. If transmission of sync frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each even communication cycle. |
| 7-4   | VSAO     | 0-Fh  | Valid synch frames channel A, odd communication cycle. Holds the number of valid sync frames received and transmitted on channel A in the odd communication cycle. If transmission of sync frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each odd communication cycle.    |
| 3-0   | VSAE     | 0-Fh  | Valid synch frames channel A, even communication cycle. Holds the number of valid sync frames received and transmitted on channel A in the even communication cycle. If transmission of sync frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each even communication cycle. |

**NOTE:** The bit fields **VSBO(3-0)**, **VSBE(3-0)**, **VSAO(3-0)**, **VSAE(3-0)** are only valid if the respective channel is assigned to the communication controller by **SUCC1.CCHA** or **SUCC1.CCHB**.

### 26.19.2.4.8 Symbol Window and NIT Status (SWNIT)

Symbol window related status information. Updated by the communication controller at the end of the symbol window for each channel. During startup the status data is not updated. This register is reset when the Communication Controller leaves CONFIG state or enters STARTUP state.

Figure 26-146 and Table 26-133 illustrate this register.

**Figure 26-146. Symbol Window and NIT Status Register (SWNIT) [offset\_CC = 124h]**

|     |       |       | Syntax error during symbol window detected on channel A            |

#### 26.19.2.4.9 Aggregated Channel Status (ACS)

The aggregated channel status provides the host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception. The aggregated channel status also includes status data from the symbol phase and the network idle time. The status data is updated (set) after each slot and aggregated until it is reset by the host. During startup the status data is not updated. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect on the flag. This register is reset when the Communication Controller leaves CONFIG state or enters STARTUP state.

Figure 26-147 and Table 26-134 illustrate this register.

**Figure 26-147. Aggregated Channel Status Register (ACS) [offset\_CC = 128h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-134. Aggregated Channel Status Register (ACS) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                               |
|-------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-13 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                    |
| 12    | SBVB     | 0     | Slot boundary violation on channel B. One or more slot boundary violations were observed on channel B at any time during the observation period (static or dynamic slots including symbol window and NIT).                                                                                                                |
|       |          | 1     | No slot boundary violation observed                                                                                                                                                                                                                                                                                       |

### 26.19.2.4.10 Even Sync ID [1. . .15] (ESIDn)

Registers ESID1 to ESID15 hold the frame IDs of the sync frames received in **even** communication cycles, assorted in ascending order, with register ESID1 holding the lowest received sync frame ID. If the node transmits a sync frame in an even communication cycle by itself, register ESID1 holds the respective sync frame ID as configured in message buffer 0. The value is updated during the NIT of each even communication cycle. This register is reset when the Communication Controller leaves CONFIG state or enters STARTUP state.

Figure 26-148 and Table 26-135 illustrate this register.

**Figure 26-148. Even Sync ID Register [1. . .15] (ESIDn) [offset\_CC = 130h-168h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-135. Even Sync ID Register [1...15] (ESIDn) Field Descriptions**

| Bit   | Field    | Value  | Description                                                                                                                                                                                      |

| 9-0   | EID      |        | Even Sync ID. Sync frame ID even communication cycle.                                                                                                                                            |

### 26.19.2.4.11 Odd Sync ID [1. .15] (OSIDn)

Registers OSID1 to OSID15 hold the frame IDs of the sync frames received in **odd** communication cycles, assorted in ascending order, with register OSID1 holding the lowest received sync frame ID. If the node transmits a sync frame in an odd communication cycle by itself, register OSID1 holds the respective sync frame ID as configured in message buffer 0. The value is updated during the NIT of each odd communication cycle. This register is reset when the Communication Controller leaves CONFIG state or enters STARTUP state.

Figure 26-149 and Table 26-136 illustrate this register.

**Figure 26-149. Odd Sync ID Register [1. .15] (OSIDn) [offset\_CC = 170h-1A8h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

### 26.19.2.4.12 Network Management Vector [1. . 3] (NMVn)

The three network management registers hold the accrued NM vector (configurable 0-12 bytes). The accrued NM vector is generated by the communication controller by bit-wise ORing each NM vector received (valid frames with PPI = 1) on each channel.

The communication controller updates the NM vector at the end of each communication cycle as long as the communication controller is either in NORMAL\_ACTIVE or NORMAL\_PASSIVE state.

NMVn-bytes exceeding the configured NM vector length are not valid.

Figure 26-150 illustrates these registers and Table 26-137 shows the assignment of the data bytes to the network management vector.

**Figure 26-150. Network Management Register [1. . 3] (NMVn) [offset\_CC = 1B0h-1B8h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

## 26.19.2.5 Message Buffer Control Registers

### 26.19.2.5.1 Message RAM Configuration (MRC)

The message RAM Configuration register defines the number of message buffers assigned to the static segment, dynamic segment, and FIFO. The register can be written during DEFAULT\_CONFIG or CONFIG state only.

Figure 26-151 and Table 26-138 illustrate this register.

**Figure 26-151. Message RAM Configuration Register (MRC) [offset\_CC = 300h]**

|          |    |       |      |       |         |    |

| R/W-0    |    |       |      | R/W-0 |         |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; \*These bits can be updated in DEFAULT\_CONFIG or CONFIG state only

**Table 26-138. Message RAM Configuration Register (MRC) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-27 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 26    | SPLM     | 0     | Sync Frame Payload Multiplex. This bit is only evaluated if the node is configured as sync node (SUCC1.TXSY = '1') or for single slot mode operation (SUCC1.TSM = '1'). When this bit is set to '1' message buffers 0 and 1 are dedicated for sync frame transmission with different payload data on channel A and B. When this bit is set to '0', sync frames are transmitted from message buffer 0 with the same payload data on both channels. Note that the channel filter configuration for message buffer 0 resp. message buffer 1 has to be chosen accordingly. |
|       |          | 1     | Only message buffer 0 locked against reconfiguration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|       |          | 1     | Both message buffers 0 and 1 are locked against reconfiguration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 25-24 | SEC      | 0     | Secure Buffers. Not evaluated when the communication controller is in DEFAULT_CONFIG or CONFIG state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|       |          | ≥ 80h | No dynamic buffers configured                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**NOTE:** In case the node is configured as sync node (SUCC1.TXSY = '1') or for single slot mode operation (SUCC1.TSM = '1'), message buffer 0 resp. 1 is reserved for sync frames or single slot frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation message buffer 0 resp. 1 is treated like all other message buffers.

**Table 26-139. Buffer Configuration**

The programmer must ensure that the configuration defined by FDB(7-0), FFB(7-0), and LCB(7-0) is valid.

**NOTE:** The communication controller does not check for erroneous configurations.

**NOTE: Maximum Number of Header Sections**

The maximum number of header sections is 128. This means a maximum of 128 message buffers can be configured. The maximum length of the data sections is 254 bytes. The length of the data section may be configured different for each message buffer. In case two or more message buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the "Static Buffers" or at the beginning of the "Static + Dynamic Buffers" section. The FlexRay protocol specification requires that each node has to send a frame in its key slot. Therefore at least message buffer 0 is reserved for transmission in the key slot. Due to this requirement a maximum number of 127 message buffers can be assigned to the FIFO. Nevertheless, a non protocol conform configuration without a transmission slot in the static segment would still be operational. The payload length configured and the length of the data sections need to be configured identical for all message buffers belonging to the FIFO via WRHS2.PLC[6:0] and WRHS3.DP[10:0]. When the communication controller is not in DEFAULT\_CONFIG or CONFIG state reconfiguration of message buffers belonging to the FIFO is locked.

### 26.19.2.5.2 FIFO Rejection Filter (FRF)

The FIFO rejection filter defines a user specified sequence of bits with which channel, frame ID, and cycle count of the incoming frames are compared. Together with the FIFO rejection filter mask (FRFM), this register determines whether a message is rejected by the FIFO. The FRF register can be written during DEFAULT\_CONFIG or CONFIG state only.

Figure 26-152 and Table 26-140 illustrate this register.

**Figure 26-152. FIFO Rejection Filter Register (FRF) [offset\_CC = 304h]**

### 26.19.2.5.3 FIFO Rejection Filter Mask (FRFM)

The FIFO rejection filter mask specifies which of the corresponding frame ID filter bits are relevant for rejection filtering. If a bit is set, it indicates that the state of the corresponding bit in the FRF register will not be considered for rejection filtering. The FRFM register can be written during DEFAULT\_CONFIG or CONFIG state only.

Figure 26-153 and Table 26-141 illustrate this register.

**Figure 26-153. FIFO Rejection Filter Mask Register (FRFM) [offset\_CC = 308h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; \*These bits can be updated in DEFAULT\_CONFIG or CONFIG state only

### Table 26-141. FIFO Rejection Filter Mask Register (FRFM) Field Descriptions

| Bit   | Field    | Value | Description                                                        |
|-------|----------|-------|--------------------------------------------------------------------|
| 31-13 | Reserved | 0     | Read returns 0. Writes have no effect.                             |
| 12-2  | MFID     |       | Mask Frame ID Filter                                               |
|       |          | 0     | Corresponding frame ID filter bit is used for rejection filtering. |
|       |          | 1     | Ignore corresponding frame ID filter bit.                          |
| 1-0   | Reserved | 0     | Read returns 0. Writes have no effect.                             |

#### 26.19.2.5.4 *FIFO Critical Level (FCL)*

The communication controller accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Figure 26-154 and Table 26-142 illustrate this register.

**Figure 26-154. FIFO Critical Level Register (FCL) [offset\_CC = 30Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; \*These bits can be updated in DEFAULT\_CONFIG or CONFIG state only

### Table 26-142. FIFO Critical Level Register (FCL) Field Descriptions

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                              |
|------|----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                   |
| 7-0  | CL       |       | Critical Level. When the receive FIFO fill level FSR.RFFL[7:0] is equal or greater than the critical level configured by CL[7:0], the receive FIFO critical level flag FSR.RFCL is set. If CL[7:0] is programmed to values > 128, bit FSR.RFCL is never set. When FSR.RFCL changes from '0' to '1' bit SIR.RFCL is set to '1', and if enabled, an interrupt is generated |

## 26.19.2.6 Message Buffer Status Registers

### 26.19.2.6.1 Message Handler Status (MHDS)

A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. A hardware reset will also clear the register.

Figure 26-155 and Table 26-143 illustrate this register.

**Figure 26-155. Message Handler Status (MHDS) [offset\_CC = 310h]**

|      |     |     |    |      |       |       |       |       |       |      |       |

It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment. |

### 26.19.2.6.3 FIFO Status Register (FSR)

The register is reset when the communication controller leaves CONFIG state, enters STARTUP state, or by CHI command CLEAR\_RAMs..

Figure 26-157 and Table 26-145 illustrate this register.

**Figure 26-157. FIFO Status Register (FSR) [offset\_CC = 318h]**

| 15-8  | RFFL     | 0-7Fh  | Receive FIFO Fill Level. Number of FIFO buffers filled with new data not yet read by the Host.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 7-7   | Reserved | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 2     | RFO      | 0<br>1 | Receive FIFO Overrun. The flag is set by the communication controller when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, interrupt flag RFO in the Error Interrupt Register (EIR) is set. The flag is cleared by the next FIFO read access issued by the Host.<br>No receive FIFO overrun detected<br>A receive FIFO overrun has been detected                                                                               |
| 1     | RFCL     | 0<br>1 | Receive FIFO Critical Level. This flag is set when the receive FIFO fill level RFFL[7:0] is equal or greater than the critical level as configured by CL[7:0] in the FIFO Critical Level register (FCL). The flag is cleared by the communication controller as soon as RFFL[7:0] drops below FCL.CL[7:0]. When RFCL changes from '0' to '1' the RFCL flag in the Status Interrupt register (SIR) is set to '1', and if enabled, an interrupt is generated.<br>Receive FIFO below critical level<br>Receive FIFO critical level reached |
| 0     | RFNE     | 0<br>1 | Receive FIFO Not Empty. This flag is set by the communication controller when a received valid frame (data or null frame depending on rejection mask) was stored in the FIFO. In addition, interrupt flag RFNE in the Status Interrupt register (SR) is set. The bit is reset after the Host has read all message from the FIFO.<br>Receive FIFO is empty<br>Receive FIFO is not empty                                                                                                                                                  |

#### 26.19.2.6.4 Message Handler Constraints Flags (MHDF)

Some constraints exist for the Message Handler regarding VBUSclk frequency, Message RAM configuration, and FlexRay bus traffic. In order to simplify software development, constraints violations are reported by setting flags in the MHDF.

A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect on the flag. A hardware reset will also clear the register. The register is reset when the communication controller leaves CONFIG state, enters STARTUP state, or by CHI command CLEAR\_RAMs.

Figure 26-158 and Table 26-146 illustrate this register.

**Figure 26-158. Message Handler Constraints Flags (MHDF) [offset\_CC = 31Ch]**

**Table 26-146. Message Handler Constraint Flags (MHDF) Field Descriptions (continued)**

| Bit | Field | Value | Description                                                                                                                                                                                                         |
|-----|-------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | SNUB  | 0     | Status not updated channel B. This flag is set by the communication controller when the Message Handler, due to overload condition, was not able to update a message buffer's status MBS with respect to channel B. |
|     |       | 1     | No overload condition occurred when updating MBS for channel B<br>MBS for channel B not updated                                                                                                                     |
| 0   | SNUA  | 0     | Status not updated channel A. This flag is set by the communication controller when the Message Handler, due to overload condition, was not able to update a message buffer's status MBS with respect to channel A. |
|     |       | 1     | No overload condition occurred when updating MBS for channel A<br>MBS for channel A not updated                                                                                                                     |

**NOTE:** When one of the flags SNUA, SNUB, FNFA, FNFB, TBFA, TBFB, WAHP changes from '0' to '1', interrupt flag MHF in the Error Interrupt register ( EIR) is set to '1'.

#### 26.19.2.6.5 Transmission Request 1/2/3/4 (TXRQ1/2/3/4)

These four registers reflect the state of the TXR flags of all configured message buffers. The flags are evaluated for transmit buffers only. If the number of configured message buffers is less than 128, the remaining TXR flags have no meaning.

Figure 26-159 through Figure 26-162 and Table 26-147 illustrate these registers.

**Figure 26-159. Transmission Request Register 4 (TXRQ4) [offset\_CC = 32Ch]**

| Bit   | Field | Value | Description                                                                                                                                                                                                              |
|-------|-------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 127-0 | TXR   | 0     | Transmission request.<br>The respective message buffer is not ready for transmission.                                                                                                                                    |
|       |       | 1     | If the flag is set, the respective message buffer is ready for transmission. Respectively, transmission of this message buffer is in progress. In single-shot mode the flags are reset after transmission has completed. |

#### 26.19.2.6.6 New Data 1/2/3/4 (NDAT1/2/3/4)

The four registers reflect the state of the ND flags of all configured message buffers. **ND** flags corresponding to transmit buffers have no meaning. If the number of configured message buffers is less than 128, the remaining ND flags have no meaning. The registers are reset when the communication controller leaves CONFIG state or enters STARTUP state.

Figure 26-163 through Figure 26-166 and Table 26-148 illustrate these registers.

**Figure 26-163. New Data Register 4 (NDAT4) [offset\_CC = 33Ch]**

| Bit   | Field | Value | Description                                                                                                                                                                                                                                                                                                               |
|-------|-------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 127-0 | ND    |       | New data.                                                                                                                                                                                                                                                                                                                 |
|       |       | 0     | The flags are reset when the header section of the corresponding message buffer is reconfigured or when the data section has been transferred to the output buffer.                                                                                                                                                       |
|       |       | 1     | The flags are set when a valid received data frame matches the message buffer's filter configuration, independent of the payload length received or the payload length configured for that message buffer. The flags are not set after reception of null frames except for message buffers belonging to the receive FIFO. |

#### 26.19.2.6.7 Message Buffer Status Changed 1/2/3/4 (MBSC1/2/3/4)

The four registers reflect the state of the MBC flags of all configured message buffers. If the number of configured message buffers is less than 128, the remaining MBC flags have no meaning.

Figure 26-167 through Figure 26-170 and Table 26-149 illustrate these registers.

**Figure 26-167. Message Buffer Status Changed Register 4 (MBSC4) [offset\_CC = 34Ch]**

| 31-0 | ETV   | 0     | Endianness Test Value. The Endianness test value is 87654321h. |

## 26.19.2.8 Input Buffer

Double buffer structure consisting of input buffer host and input buffer shadow. While the host can write to input buffer host, the transfer to the message RAM is done from input buffer shadow. The input buffer holds the header and data sections to be transferred to the selected message buffer in the message RAM. It is used to configure the message buffers in the message RAM and to update the data sections of transmit buffers.

When updating the header section of a message buffer in the Message RAM from the Input Buffer, the Message Buffer Status as described in Message Buffer Status (MBS), Message Buffer Status (MBS) is automatically reset to zero.

The header sections of message buffers belonging to the receive FIFO can only be (re)configured when the communication controller is in DEFAULT\_CONFIG or CONFIG state. For those message buffers only the payload length configured and the data pointer need to be configured by bits PLC[6:0] of the Write Header Section 2 (WRHS2) and by bits DP[10:0] of Write Header Section 3 (WRHS3). All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask.

### 26.19.2.8.1 Write Data Section [1. . .64] (WRDSn)

Holds the data words to be transferred to the data section of the addressed message buffer. The data words ( $DW_n$ ) are written to the message RAM in transmission order from  $DW_1$  (byte0, byte1) to  $DW_{PL}$  ( $DW_{PL}$  = number of data words as defined by the payload length configured in PLC(6-0) of the Write Header Section 2 (WRHS2).

Figure 26-173 and Table 26-153 illustrate this register.

**Figure 26-173. Write Data Section [1. . .64] Register (WRDSn) [offset\_CC = 400h-4FCh]**

### 26.19.2.8.5 Input Buffer Command Mask (IBCM)

Configures how the message buffer in the message RAM selected by the input buffer command request register is updated. When IBF host and IBF shadow are swapped, also mask bits LSH, LDSH, and STXRH are swapped with bits LHSS, LDSS, and STXRS to keep them attached to the respective input buffer transfer.

Figure 26-177 and Table 26-158 illustrate this register.

**Figure 26-177. Input Buffer Command Mask Register (IBCM) [offset\_CC = 510h]**

### 26.19.2.8.6 Input Buffer Command Request (IBCR)

When the host writes the number of a target message buffer in the message RAM to IBRH(6-0) in the input buffer command request register, IBF host and IBF shadow are swapped. In addition the message buffer numbers stored under IBRH(6-0) and IBRS(6-0) are also swapped.

With this write operation the IBSYS bit in the input buffer command request register is set to 1. The message handler then starts to transfer the contents of IBF shadow to the message buffer in the message RAM selected by IBRS(6-0).

While the message handler transfers the data from IBF shadow to the target message buffer in the message RAM, the host may configure the next message in the IBF host. After the transfer between IBF shadow and the message RAM has completed, the IBSYS bit is set back to 0 and the next transfer to the message RAM may be started by the host by writing the respective target message buffer number to IBRH(6-0).

If a write access to IBRH(6-0) occurs while IBSYS is 1, IBSYH is set to 1. After completion of the ongoing data transfer from IBF shadow to the message RAM, IBF host and IBF shadow are swapped, IBSYH is reset to 0. IBSYS remains set to 1, and the next transfer to the message RAM is started. In addition the message buffer numbers stored under IBRH(6-0) and IBRS(6-0) are also swapped.

Any write access to an Input Buffer Register while both IBSYS and IBSYH are set will cause the error flag IIBA in the Error Interrupt Register ( EIR) to be set. In this case the Input Buffer will not be changed.

Figure 26-178 and Table 26-159 illustrate this register.

| 6-0   | IBRH     | 0-7Fh  | Input buffer request host. Selects the target message buffer in the Message RAM for data transfer from Input Buffer.                                                                                                                                                                      |

### 26.19.2.9 Output Buffer

Double buffer structure consisting of output buffer host and output buffer shadow. While the host can read from output buffer host, the transfer from the message RAM is done to output buffer shadow. The output buffer holds the header and data sections of requested message buffers transferred from the message RAM. Used to read out message buffers from the message RAM.

#### 26.19.2.9.1 Read Data Section [1. . 64] (RDDS<sub>n</sub>)

Holds the data words read from the data section of the addressed message buffer. The data words (DW<sub>*n*</sub>) are read from the message RAM in reception order from DW<sub>1</sub>(byte0, byte1) to DW<sub>PL</sub>(DW<sub>PL</sub>= number of data words as defined by the payload length configured in bits PLC(6-0) of the Read Header Section 2 (RDHS2)).

Figure 26-179 and Table 26-160 illustrate this register.

**Figure 26-179. Read Data Section Register (RDDS<sub>n</sub>) [offset\_CC = 600h-6FCh]**

**NOTE:** The Message RAM is organized in 4-byte words. When received data is stored into a message buffer's data section, the number of 2-byte data words written into the message buffer is PLC[6:0] rounded to the next even value. PLC[6:0] should be configured identical for all message buffers belonging to the receive FIFO. Header 2 is updated from data frames only.

### 26.19.2.9.4 Read Header Section 3 (RDHS3)

Figure 26-182 and Table 26-163 illustrate this register.

**Figure 26-182. Read Header Section Register 3 (RDHS3) [offset\_CC = 708h]**

Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 10-0  | DP       |        | Data pointer. Pointer to the first 32-bit word of the data section of the addressed message buffer in the message RAM.                                                                                                                                                                                                                                                                                                                                     |

**NOTE:** Header 3 is updated from data frames only.

### 26.19.2.9.5 Message Buffer Status (MBS)

The message buffer status is updated by the communication controller with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the message buffer. The flags are updated only when the communication controller is in NORMAL\_ACTIVE or NORMAL\_PASSIVE state. If only one channel (A or B) is assigned to a message buffer, the channel-specific status flags of the other channel are written to zero. If both channels are assigned to a message buffer, the channel-specific status flags of both channels are updated. The message buffer status is updated only when the slot counter reached the configured frame ID and when the cycle counter filter matched. When the Host updates a message buffer via Input Buffer, all MBS flags are reset to zero independent of which IBCM bits are set or not.

Whenever the Message Handler changes one of the flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB the respective message buffer's MBC flag in registers MBSC1/2/3/4 is set.

Figure 26-183 and Table 26-164 illustrate this register.

|     |       | 1     | Valid frame received on channel B                                                                              |
| 0   | VFRA  |       | Valid frame received on channel A. A valid frame indication is set if a valid frame was received on channel A. |
|     |       | 0     | No valid frame received on channel A                                                                           |
|     |       | 1     | Valid frame received on channel A                                                                              |

---

**NOTE:** The status bits RESS, PPPIS, NFIS, FYNS, SFIS and RCIS are updated from both valid data and null frames. If no valid frame was received, the previous value is maintained.

---

---

**NOTE:** The FlexRay protocol specification requires that FTA, and FTB can only be reset by the CPU. Therefore the Cycle Count Status CCS[5:0] for these bits is only valid for the cycle where the bits are set to '1'.

---

### 26.19.2.9.6 Output Buffer Command Mask (OBCM)

Configures how the Output Buffer is updated from the message buffer in the Message RAM selected by bits OBRS(6-0) of the output buffer command request register. Mask bits RDSS and RHSS are copied to the register internal storage when a Message RAM transfer is requested by OBCR.REQ. When OBF host and OBF shadow are swapped, also mask bits RDSH and RHSH are swapped with bits RDSS and RHSS to keep them attached to the respective output buffer transfer.

Figure 26-184 and Table 26-165 illustrate this register.

**Figure 26-184. Output Buffer Command Mask Register (OBCM) [offset\_CC = 700h]**

|          |  |    |       |       |

| R-0      |  |    | R/W-0 | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-165. Output Buffer Command Mask Register (MBS) Field Descriptions**

| Bit   | Field    | Value | Description                                                            |
|-------|----------|-------|------------------------------------------------------------------------|
| 31-18 | Reserved | 0     | Read returns 0. Writes have no effect.                                 |
| 17    | RDSH     | 0     | Read data section host.<br>Data section is not read                    |
|       |          | 1     | Data section selected for transfer from message RAM to output buffer   |
| 16    | RHSH     | 0     | Read header section host.<br>Header section is not read                |
|       |          | 1     | Header section selected for transfer from message RAM to output buffer |
| 15-2  | Reserved | 0     | Read returns 0. Writes have no effect.                                 |
| 1     | RDSS     | 0     | Read Data Section shadow.<br>Data section is not read                  |
|       |          | 1     | Data section selected for transfer from message RAM to output buffer   |
| 0     | RHSS     | 0     | Read header section shadow<br>Header section is not read               |
|       |          | 1     | Header section selected for transfer from message RAM to output buffer |

**NOTE:** After the transfer of the header section from the message RAM to OBF shadow has completed, the message buffer status Changed flag MBS of the selected message buffer in the message buffer Changed 1,2,3,4 registers is cleared. After the transfer of the data section from the message RAM to OBF shadow has completed, the New Data flag ND of the selected message buffer in the New Data 1,2,3,4 registers is cleared.

### 26.19.2.9.7 Output Buffer Command Request (OBCR)

After setting bit REQ to 1 while OBSYS is 0, OBSYS is automatically set to 1, OBRH(6-0) is copied to the register internal storage, mask bits OBCM.RDSS and OBCM.RHSS are copied to register OBCM internal storage, and the transfer of the message buffer selected by OBRH(6-0) from the Message RAM to OBF Shadow is started. When the transfer between the Message RAM and OBF shadow has completed, this is signaled by setting OBSYS back to 0.

By setting bit VIEW to 1 while OBSYS is 0, OBF Host and OBF shadow are swapped. Additionally mask bits OBCM.RDSH and OBCM.RHSH are swapped with the register OBCM internal storage to keep them attached to the respective output buffer transfer. OBRH(6-0) signals the number of the message buffer currently accessible by the Host.

If bits REQ and VIEW are set to 1 with the same write access while OBSYS is 0, OBSYS is automatically set to 1 and OBF shadow and OBF host are swapped. Additionally mask bits OBCM.RDSH and OBCM.RHSH are swapped with the registers internal storage to keep them attached to the respective output buffer transfer. Afterwards OBRH(6-0) is copied to the register

internal storage, and the transfer of the selected message buffer from the Message RAM to OBF shadow is started. While the transfer is ongoing the Host can read the message buffer transferred by the previous transfer from OBF host. When the current transfer between Message RAM and OBF shadow has completed, this is signaled by setting OBSYS back to 0.

Any write access to OBCR(15-8) while OBSYS is set will cause the error flag IOBA in the Error Interrupt Register to be set.

In this case the output buffer will not be changed.

Figure 26-185 and Table 26-166 illustrate this register.

Writes have no effect.                                                                                                                                                                                                                                                                                    |
| 6-0 | OBRS     | 0-7Fh | Output buffer request shadow. Number of source message buffer to be transferred from the message RAM to OBF shadow. If the number of the first message buffer of the receive FIFO is written to this register, the message handler transfers the message buffer addressed by the GET Index register (GIDX) to OBF shadow. |

## 26.20 Minimum Peripheral Clock Frequency

In order to calculate the minimum peripheral clock frequency (VBUSclk) the worst case scenario has to be considered. The worst case scenario depends on the following parameters:

- maximum payload length
- minimum minislot length
- number of configured message buffers (excluding FIFO)
- used channels (single/dual channel)

Worst case scenario:

- reception of a message with a maximum payload length in slot n (n is 7,15,23,31,39,...)
- slot n+1 to n+7 are empty dynamic slots (minislot) and configured as receive buffer
- the find-sequence (usually started in slot 8,16,24,32,40,...) has to scan the maximum number of configured buffers
- the number of concurrent tasks has its maximum value of 3

The find-sequence is executed each 8 slots (slot 8,16,24,32,40,...). It has to be finished until the next find-sequence is requested.

The duration of a Transient Buffer RAM (TBF) transfer to the Message Buffer RAM (MBF) varies from 4 (header section only) to 68 (header + maximum data section) time steps plus a setup time of 6 time steps.

$$VBUScycles_{t2m} = (\text{number of concurrent tasks}) \times (6 + (\text{number of 4-byte words}))$$

A Slot Status (SS) transfer to the Message Buffer RAM (MBF) has a length of 1 time step plus a setup time of 4 time steps.

$$VBUSclk_{ss2m} = (\text{number of concurrent tasks}) \times 5$$

The find sequence has a maximum length of 128 (maximum number of buffers) time steps plus a setup time of 2 time steps.

$$VBUSclk_{find} = (\text{number of concurrent tasks}) \times (2 + (\text{number of configured buffers}))$$

A minislot has a length of 2 to 63 macroticks (MTicks). The minimum nominal macrotick period (MTcycle) is 1μs. A sequence of 8 minislots has a length of

$$t_{8minislots} = 8 \times MTicks \times MTcycle$$

The worst case VCLK cycle period can be calculated as follows:

$$t_{8minislots} \geq \frac{VBUScycles_{t2m} + (7 \times VBUScycles_{ss2m}) + VBUScycles_{find}}{VBUSclk} \quad (36)$$

$$\frac{1}{VBUS_{clk}} \leq \frac{t_{8minislots}}{VBUScycle_{t2m} + (7 \times VBUScycle_{ss2m}) + VBUScycle_{find}} [\mu s] \quad (37)$$

$$\text{minimum } t_{8minislots} = 8 * 2 * 1 \mu s = 16 \mu s$$

$$\text{maximum } VBUScycle_{t2m} = 3 * (6 + 68) = 222$$

$$\text{maximum } VBUScycle_{ss2m} = 3 * 5 = 15$$

$$\text{maximum } VBUScycle_{find} = 3 * (2 + 128) = 390$$

$$\frac{1}{VBUSclk} \leq \frac{16\mu s}{222 + 7 \times 15 + 390} = 22.32ns \quad (38)$$

The minimum peripheral clock frequency for this worst case scenario is 44,8125 MHz.

## 26.21 Assignment of FlexRay Configuration Parameters

The following table shows the assignment of the FlexRay parameters as defined in the FlexRay Protocol Specification and the corresponding bit fields of the FlexRay module.

**Table 26-167. Assignment of FlexRay Configuration Parameters**

| Parameter                         | Bit(field)           |
|-----------------------------------|----------------------|
| pKeySlotUsedForStartup            | SUCC1.TXST           |
| pKeySlotUsedForSync               | SUCC1.TXSY           |
| gColdStartAttempts                | SUCC1.CSA(4-0)       |
| pAllowPassiveToActive             | SUCC1.PTA(4-0)       |
| pWakeupChannel                    | SUCC1.WUCS           |
| pSingleSlotEnabled                | SUCC1.TSM            |
| pAllowHaltDueToClock              | SUCC1.HCSE           |
| pChannels                         | SUCC1.CCHASUCC1.CCHB |
| pdListenTimeOut                   | SUCC2.LT(20-0)       |
| gListenNoise                      | SUCC2.LTN(3-0)       |
| gMaxWithoutClockCorrectionPassive | SUCC3.WCP(3-0)       |
| gMaxWithoutClockCorrectionFatal   | SUCC3.WCF(3-0)       |
| gNetworkManagementVectorLength    | NEMC.NML(3-0)        |
| gdTSSTransmitter                  | PRTC1.TSST(3-0)      |
| gdCASRxLowMax                     | PRTC1.CASM(6-0)      |
| gdSampleClockPeriod               | PRTC1.BRP(1-0)       |
| pSamplesPerMicrotick              | PRTC1.BRP(1-0)       |
| gdWakeupSymbolRxWindow            | PRTC1.RXW(8-0)       |
| pWakeupPattern                    | PRTC1.RWP(5-0)       |
| gdWakeupSymbolRxIdle              | PRTC2.RXI(5-0)       |
| gdWakeupSymbolRxLow               | PRTC2.RXL(5-0)       |
| gdWakeupSymbolTxIdle              | PRTC2.TXI(7-0)       |
| gdWakeupSymbolTxLow               | PRTC2.TXL(5-0)       |
| gPayloadLengthStatic              | MHDC.SFDL(6-0)       |
| pLatestTx                         | MHDC.SLT(12-0)       |

## 26.22 Emulation/Debug Support

For any debug transactions on the bus interface (VBUSP or OCP), the responses are normal except for the following:

1. Reads will not clear "read-clear" type of bits during the same.
2. User mode writes are allowed to "privilege mode write only" bits as well.

## Controller Area Network (DCAN) Module

This chapter describes the controller area network (DCAN) module.

---

**NOTE:** This chapter describes a superset implementation of the DCAN module. Consult your device-specific datasheet to identify the applicability of the DMA-related features, the number of instantiations of the DCAN IP, and the number of mailboxes supported on your specific device being used.

---

## 27.1 Overview

The Controller Area Network is a high-integrity, serial, multi-master communication protocol for distributed real-time applications. This CAN module is implemented according to ISO 11898-1 and is suitable for industrial, automotive and general embedded communications.

### 27.1.1 Features

The DCAN module provides the following features:

#### Protocol

- Supports CAN protocol version 2.0 part A, B

#### Speed

- Bit rates up to 1 MBit/s

#### MailBox

- Configurable Message objects
- Individual identifier masks for each message object
- Programmable FIFO mode for message objects

#### High Speed MailBox Access

- DMA access to Message RAM.

#### Power

- Global power down and wakeup support
- Local power down and wakeup support

#### Debug

- Suspend mode for debug support
- Programmable loop-back modes for self-test operation
- Direct access to Message RAM in test mode
- Supports Two interrupt lines - Level 0 and Level 1

#### Others

- Automatic Message RAM initialization
- Automatic bus on after Bus-Off state by a programmable 32-bit timer
- CAN Rx / Tx pins configurable as general purpose IO pins
- Software module reset
- Message RAM parity check mechanism
- Dual clock source to reduce jitter

### 27.1.2 Functional Description

The CAN protocol is an ISO standard (ISO 11898) for serial data communication. This protocol uses Non-Return To Zero (NRZ) with bit-stuffing. And the communication is carried over a two-wire balanced signaling scheme.

The DCAN data communication happens through the CAN\_TX and CAN\_RX pins. An additional transceiver hardware is required for the connection to the physical layer (CAN bus) CAN\_High and CAN\_Low.

The DCAN register set can be accessed directly by the CPU. These registers are used to control and configure the CAN module and the Message RAM.

Individual CAN message objects should be configured for communication over a CAN network. The message objects and identifier masks are stored in the Message RAM.

The CAN module internally handles functions such acceptance filtering, transfer of messages from and to the Message RAM, handling of transmission requests as well as the generation of interrupts or DMA requests.

## 27.2 CAN Blocks

The DCAN Module, shown in [Figure 27-1](#), comprises of the following basic blocks.

### 27.2.1 CAN Core

The CAN Core consists of the CAN Protocol Controller and the Rx/Tx Shift Register. It handles all ISO 11898-1 protocol functions.

### 27.2.2 Message RAM

The DCAN Message RAM enables storage of CAN messages.

### 27.2.3 Message Handler

The Message Handler is a state machine which controls the data transfer between the single ported Message RAM and the CAN Core's Rx/Tx Shift Register. It also handles acceptance filtering and the interrupt/DMA request generation as programmed in the control registers.

**Figure 27-1. Block Diagram**

### 27.2.4 Message RAM Interface

The Interface Register sets control the CPU read and write accesses to the Message RAM.

There are three interface registers IF1, IF2 and IF3.

IF1 and IF2 Interface Registers sets for read and write access.

IF3 Interface Register set for read access only.

The Interface Registers have the same word-length as the Message RAM.

Additional information can be found in [Section 27.6](#).

### 27.2.5 Register and Message Object Access

During normal operation, data consistency of the message objects is guaranteed by indirectly accessing the message objects through the interface registers IF1 and IF2.

In order to be able to perform tests on the message object memory, a dedicated test mode has been implemented, which allows direct access by either the CPU or DMA. During normal operation direct access has to be avoided.

### 27.2.6 Dual Clock Source

Two clock domains are provided to the DCAN module:

1. VCLK - The peripheral synchronous clock domain as the general module clock source.
2. VCLKA - The peripheral asynchronous clock source domain provided to the CAN core as clock source (CAN\_CLK) for generating the CAN Bit Timing.

If a frequency modulated clock output from FMPLL is used as the VCLK source, then VCLKA should be derived from an unmodulated clock source (for example, OSCIN source).

The clock source for VCLKA is selected by the Peripheral Asynchronous Clock Source Register in the system module.

Both clock domains can be derived from the same clock source (so that VCLK = VCLKA). However, if frequency modulation in the FMPLL is enabled (spread spectrum clock), then due to the high precision clocking requirements of the CAN Core, the FMPLL clock source should not be used for VCLKA. Alternatively, a separate clock without any modulation (for example, derived directly from the OSCIN clock) should be used for VCLKA.

Please refer to the system module reference guide and the device datasheet for more information how to configure the relevant clock source registers in the system module.

Between the two clock domains, a synchronization mechanism is implemented in the DCAN module in order to ensure correct data transfer.

---

**NOTE:** If the dual clock functionality is used, then VCLK must always be higher or equal to CAN\_CLK (derived from the asynchronous clock source), in order to achieve a stable functionality of the DCAN. Here also the frequency shift of the modulated VCLK has to be considered:

$$f_{0, VCLK} \pm \Delta f_{FM, VCLK} \geq f_{CANCLK}$$

The CAN Core has to be programmed to at least 8 clock cycles per bit time. To achieve a transfer rate of 1 MBaud when using the asynchronous clock domain as the clock source for CAN\_CLK, an oscillator frequency of 8MHz or higher has to be used.

---

## 27.3 CAN Bit Timing

The DCAN supports bit rates between less than 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The Bit timing parameters can be configured individually for each CAN node, creating a common Bit rate even though the CAN nodes' oscillator periods ( $f_{osc}$ ) may be different.

### 27.3.1 Bit Time and Bit Rate

According to the CAN specification, the Bit time is divided into four segments (see Figure 27-2):

- Synchronization Segment (Sync\_Seg)
- Propagation Time Segment (Prop\_Seg)
- Phase Buffer Segment 1 (Phase\_Seg1)
- Phase Buffer Segment 2 (Phase\_Seg2)

**Figure 27-2. Bit Timing**

Each segment consists of a specific number of time quanta. The length of one time quantum ( $t_q$ ), which is the basic time unit of the bit time, is given by the CAN\_CLK and the Baud Rate Prescalers (BRPE and BRP). With these two Baud Rate Prescalers combined, divider values from 1 to 1024 can be programmed:

$$t_q = \text{Baud Rate Prescaler} / \text{CAN\_CLK}$$

Apart from the fixed length of the synchronization segment, these numbers are programmable.

Table 27-1 describes the minimum programmable ranges required by the CAN protocol. A given bit rate may be met by different Bit time configurations.

**NOTE:** For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

**Table 27-1. Parameters of the CAN Bit Time**

| Parameter                        | Range           | Remark                                             |
|----------------------------------|-----------------|----------------------------------------------------|
| Sync_Seg                         | 1 $t_q$ (fixed) | Synchronization of bus input to CAN_CLK            |
| Prop_Seg                         | [1 ... 8] $t_q$ | Compensates for the physical delay times           |
| Phase_Seg1                       | [1 ... 8] $t_q$ | May be lengthened temporarily by synchronization   |
| Phase_Seg2                       | [1 ... 8] $t_q$ | May be shortened temporarily by synchronization    |
| Synchronization Jump Width (SJW) | [1 ... 4] $t_q$ | May not be longer than either Phase Buffer Segment |

### 27.3.1.1 Synchronization Segment

The Synchronization Segment (Sync\_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync\_Seg, its distance to the Sync\_Seg is called the phase error of this edge.

### 27.3.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

### 27.3.1.3 Phase Buffer Segments and Synchronization

The Phase Buffer Segments (Phase\_Seg1 and Phase\_Seg2) and the Synchronization Jump Width (SJW) are used to compensate for the oscillator tolerance.

The Phase Buffer Segments surround the sample point. The Phase Buffer Segments may be lengthened or shortened by synchronization.

The Synchronization Jump Width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync\_Seg, otherwise its distance to the Sync\_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync\_Seg, the phase error is negative, else it is positive.

### 27.3.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range  $df$  for an oscillator's frequency  $f_{osc}$  around the nominal frequency  $f_{nom}$  with:

$$(1-df) \times f_{nom} \leq f_{osc} \leq (1+df) \times f_{nom} \quad (39)$$

depends on the proportions of Phase\_Seg1, Phase\_Seg2, SJW, and the bit time. The maximum tolerance  $df$  is defined by two conditions (both shall be met):

$$I: df \leq \frac{\min(TSeg1, TSeg2)}{2 \times (13 \times (bit\_time - TSeg2))}$$

$$II: df \leq \frac{SJW}{20 \times bit\_time} \quad (40)$$

It has to be considered that SJW may not be larger than the smaller of the Phase Buffer Segments and that the Propagation Time Segment limits that part of the bit time that may be used for the Phase Buffer Segments.

The combination Prop\_Seg = 1 and Phase\_Seg1 = Phase\_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a Propagation Time Segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8  $\mu$ s) with a bus length of 40 m.

### 27.3.2 DCAN Bit Timing Registers

In the DCAN, the bit timing configuration is programmed in two register bytes, additionally a third byte for a baud rate prescaler extension of 4 bits (BREP) is provided. The sum of Prop\_Seg and Phase\_Seg1 (as TSEG1) is combined with Phase\_Seg2 (as TSEG2) in one byte, SJW and BRP (plus BRPE in third byte) are combined in the other byte

In this bit timing register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1... n], values in the range of [0 ... n-1] are programmed. That way, SJW (functional range of [1 ... 4]) is represented by only two bits.

Therefore the length of the Bit time is (programmed values)  $[TSEG1 + TSEG2 + 3] t_q$  or (functional values)  $[Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2] t_q$ .

The data in the Bit Timing Register (BTR) is the configuration input of the CAN protocol controller. The Baud Rate Prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the Bit Timing Logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

#### 27.3.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting Bit time ( $1 / \text{Bit rate}$ ) must be an integer multiple of the CAN clock period.

---

**NOTE:** 8 MHz is the minimum CAN clock frequency required to operate the DCAN at a bit rate of 1 MBit/s.

---

The bit time may consist of 8 to 25 time quanta. The length of the time quantum  $t_q$  is defined by the Baud Rate Prescaler with  $t_q = (\text{Baud Rate Prescaler}) / \text{CAN\_CLK}$ . Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop\_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop\_Seg is converted into time quanta (rounded up to the nearest integer multiple of  $t_q$ ).

The Sync\_Seg is 1  $t_q$  long (fixed), leaving  $(\text{bit time} - \text{Prop\_Seg} - 1) t_q$  for the two Phase Buffer Segments. If the number of remaining  $t_q$  is even, the Phase Buffer Segments have the same length, Phase\_Seg2 = Phase\_Seg1, else Phase\_Seg2 = Phase\_Seg1 + 1.

The minimum nominal length of Phase\_Seg2 has to be regarded as well. Phase\_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of [0 ... 2]  $t_q$ .

The length of the Synchronization Jump Width is set to its maximum value, which is the minimum of 4 and Phase\_Seg1.

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration that allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the Bit Timing Register:

```
Tseg2 = Phase_Seg2-1
Tseg1 = Phase_Seg1+ Prop_Seg-1
SJW = SynchronizationJumpWidth-1
BRP = Prescaler-1
```

### 27.3.2.2 Example for Bit Timing at High Baudrate

In this example, the frequency of CAN\_CLK is 10 MHz, BRP is 0, the bit rate is 1 MBit/s.

|                           |      |    |   |                                                                |      |
|---------------------------|------|----|---|----------------------------------------------------------------|------|
| $t_q$                     | 100  | ns | = | $t_{CAN\_CLK}$                                                 |      |
| delay of bus driver       | 60   | ns |   |                                                                |      |
| delay of receiver circuit | 40   | ns |   |                                                                |      |
| delay of bus line (40m)   | 220  | ns |   |                                                                |      |
| $t_{Prop}$                | 700  | ns | = | $INT(2 \cdot \text{delays} + 1) = 7 \cdot t_q$                 |      |
| $t_{SJW}$                 | 100  | ns | = | $1 \cdot t_q$                                                  |      |
| $t_{TSeg1}$               | 800  | ns | = | $t_{Prop} + t_{SJW}$                                           |      |
| $t_{TSeg2}$               | 100  | ns | = | Information Processing Time + $1 \cdot t_q$                    |      |
| $t_{Sync-Seg}$            | 100  | ns | = | $1 \cdot t_q$                                                  |      |
| bit time                  | 1000 | ns | = | $t_{Sync-Seg} + t_{TSeg1} + t_{TSeg2}$                         |      |
| tolerance for CAN_CLK     | 1.58 | %  | = | $\frac{\min(TSeg1, TSeg2)}{2x(13x(\text{bit\_time} - TSeg2))}$ | (41) |
|                           |      |    | = | $\frac{0.1 \mu s}{2x(13x(1 \mu s - 0.1 \mu s))}$               | (42) |

In this example, the concatenated bit time parameters are  $(1-1)_3 \& (8-1)_4 \& (1-1)_2 \& (1-1)_6$ , so the Bit Timing Register is programmed to 0000 0700h.

### 27.3.2.3 Example for Bit Timing at Low Baudrate

In this example, the frequency of CAN\_CLK is 2 MHz, BRP is 1, the bit rate is 100 KBit/s.

|                           |      |         |   |                                                                |      |
|---------------------------|------|---------|---|----------------------------------------------------------------|------|
| $t_q$                     | 100  | ns      | = | $2 \cdot t_{CAN\_CLK}$                                         |      |
| delay of bus driver       | 200  | ns      |   |                                                                |      |
| delay of receiver circuit | 80   | ns      |   |                                                                |      |
| delay of bus line (40m)   | 220  | ns      |   |                                                                |      |
| $t_{Prop}$                | 1    | $\mu s$ | = | $1 \cdot t_q$                                                  |      |
| $t_{SJW}$                 | 4    | $\mu s$ | = | $4 \cdot t_q$                                                  |      |
| $t_{TSeg1}$               | 5    | $\mu s$ | = | $t_{Prop} + t_{SJW}$                                           |      |
| $t_{TSeg2}$               | 3    | $\mu s$ | = | Information Processing Time + $3 \cdot t_q$                    |      |
| $t_{Sync-Seg}$            | 1    | $\mu s$ | = | $1 \cdot t_q$                                                  |      |
| bit time                  | 9    | $\mu s$ | = | $t_{Sync-Seg} + t_{TSeg1} + t_{TSeg2}$                         |      |
| tolerance for CAN_CLK     | 0.43 | %       | = | $\frac{\min(TSeg1, TSeg2)}{2x(13x(\text{bit\_time} - TSeg2))}$ | (43) |
|                           |      |         | = | $\frac{3 \mu s}{2x(13x(9 \mu s - 3 \mu s))}$                   | (44) |

In this example, the concatenated bit time parameters are  $(3-1)_3 \& (5-1)_4 \& (4-1)_2 \& (2-1)_6$ , so the Bit Timing Register is programmed to 0000 24C1h.

## 27.4 CAN Module Configuration

After a hardware reset all CAN protocol functions are disabled. The CAN module must be initialized and configured before it can participate on the CAN bus.

### 27.4.1 DCAN RAM Initialization through hardware

To start with a clean DCAN RAM, the complete DCAN RAM can be initialized with zeros and the ecc/parity bits set accordingly by configuring the following registers in the system module:

1. Memory Hardware Initialization Global Control Register (MINITGCR)
2. Memory Initialization Enable Register (MSINENA)

For more details on RAM hardware initialization support, refer to the system module reference guide.

### 27.4.2 CAN Module Initialization

To initialize the CAN Controller, the user has to set up the CAN Bit timing and those message objects which have to be used for CAN communication. Message objects that are not needed, can be deactivated.

So the two critical steps are:

1. Configuration of CAN Bit Timings
2. Configuration of Message Objects

#### 27.4.2.1 Software Configuration of CAN Bit Timings

This step involves configuring the CAN baud rate register with the calculated CAN bit timing value. The calculation procedure of CAN bit timing values for BTR register are mentioned in [Section 27.3](#). Refer to [Figure 27-3](#) for CAN bit timing software configuration flow.

**Figure 27-3. CAN Bit-timing Configuration**

**Step 1:** Enter “initialization mode” by setting the Init (Initialization) bit in the CAN Control Register.

While the Init bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN\_TX output is recessive (high).

The CAN error counters are not updated. Setting the Init bit does not change any other configuration register.

Also note that the CAN module is also in initialization mode on hardware reset and during Bus-Off.

**Step 2:** Set the CCE (Configure Change Enable) bit in the CAN Control Register.

The access to the Bit Timing Register for the configuration of the Bit timing is enabled when both Init and CCE bits in the CAN Control Register are set.

**Step 3:** Wait for the Init bit to get set. This would make sure that the module has entered “Initialization mode”.

**Step 4:** Write the Bit-Timing values into the BTR (Bit-Timing Register) Register.

Refer to [Section 27.3.2.1](#) for BTR value calculation for a given bit-timing.

**Step 5:** Clear the CCE bit followed by Init bit.

**Step 6:** Wait for the Init bit to clear. This would make sure that the module has come out of “initialization mode”.

After step 6 (Init bit cleared), the module will attempt a synchronization on the CAN bus, provided that the BTR settings are meeting the CAN bus parameters.

---

**NOTE:** The module would not come out of the “initialization mode” if any incorrect BTR values are written in step 4.

---

#### 27.4.2.2 Configuration of Message Objects

The whole Message RAM should be configured before putting the CAN into operation. All the message objects are deactivated by default. The user should configure the message object that are to be used to a particular identifier. The user can change the configuration of any message object or deactivate it when required.

The message objects can be configured only through the Interface registers (IFx) and the CPU does not have direct access to the message object (Message RAM) when DCAN is in operation.

To configure the message objects, the user must know about:

1. The message object structure ([Section 27.5](#))
2. The interface register set (IFx) ([Section 27.6](#))

---

**NOTE:** The message objects initialization is independent of the bit-timing configuration procedure.

---

## 27.5 Message RAM

The DCAN Message RAM contains message objects and parity bits for the message objects.

### 27.5.1 Structure of Message Objects

Figure 27-4 shows the structure of a message object.

The grayed fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

**Figure 27-4. Structure of a Message Object**

| Message Object |           |      |      |          |        |        |        |        |        |        |        |        |
|----------------|-----------|------|------|----------|--------|--------|--------|--------|--------|--------|--------|--------|
| UMask          | Msk[28:0] | MXtd | MDir | EoB      | unused | NewDat | MsgLst | RxIE   | TxIE   | IntPnd | RmtEn  | TxRqst |
| MsgVal         | ID[28:0]  | Xtd  | Dir  | DLC[3:0] | Data 0 | Data 1 | Data 2 | Data 3 | Data 4 | Data 5 | Data 6 | Data 7 |

**Table 27-2. Message Object Field Descriptions**

| Name      | Value     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MsgVal    |           | Message valid                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|           | 0         | The message object is ignored by the Message Handler.                                                                                                                                                                                                                                                                                                                                                                                         |
|           | 1         | The message object is to be used by the Message Handler.<br>Note: The CPU should reset the MsgVal bit of all unused Messages Objects during the initialization before it resets bit Init in the CAN Control Register. MsgVal must also be reset if the messages object is no longer used in operation. For reconfiguration of message objects during normal operation see <a href="#">Section 27.7.6</a> and <a href="#">Section 27.7.7</a> . |
| UMask     |           | Use Acceptance Mask                                                                                                                                                                                                                                                                                                                                                                                                                           |
|           | 0         | Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.                                                                                                                                                                                                                                                                                                                                                       |
|           | 1         | Mask bits are used for acceptance filtering.<br>Note: If the UMask bit is set to 1, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to 1.                                                                                                                                                                                                                               |
| ID[28:0]  |           | Message Identifier                                                                                                                                                                                                                                                                                                                                                                                                                            |
|           | ID[28:0]  | 29-bit ("extended") identifier bits                                                                                                                                                                                                                                                                                                                                                                                                           |
|           | ID[28:18] | 11-bit ("standard") identifier bits                                                                                                                                                                                                                                                                                                                                                                                                           |

| Data 4   |       | 5th data byte of a CAN Data Frame                                                                                                                                                                                                                                                                                                                                                                                       |
| Data 5   |       | 6th data byte of a CAN Data Frame                                                                                                                                                                                                                                                                                                                                                                                       |
| Data 6   |       | 7th data byte of a CAN Data Frame                                                                                                                                                                                                                                                                                                                                                                                       |
| Data 7   |       | 8th data byte of a CAN Data Frame<br><b>Note:</b> Byte Data 0 is the first data byte shifted into the shift register of the CAN Core during a reception, byte Data 7 is the last. When the Message Handler stores a data frame, it will write all the eight data bytes into a message object. If the Data Length Code is less than 8, the remaining bytes of the message object may be overwritten by undefined values. |

## 27.5.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:

Message RAM base address + (message object number) \* 0x20.

This means that Message Object 1 starts at offset 0x0020; Message Object 2 starts at offset 0x0040, and so on.

**NOTE:** 0 is not a valid message object number. At address 0x0000, message object number 64 is located. Writing to the address of an unimplemented message object may overwrite an implemented message object.

The base address for DCAN1 RAM is 0xFF1E 0000, DCAN2 RAM is 0xFF1C 0000, and DCAN3 RAM is 0xFF1A 0000.

Message Object number 1 has the highest priority.

**Table 27-3. Message RAM Addressing in Debug/Suspend and RDA mode**

| Message Object Number | Base Address Offset | Word Number | Debug/Suspend mode, see <a href="#">Section 27.5.3</a> | RDA mode, see <a href="#">Section 27.5.4</a> |
|-----------------------|---------------------|-------------|--------------------------------------------------------|----------------------------------------------|
| 1                     | 0x0020              | 1           | Parity                                                 | Data Bytes 4-7                               |

### 27.5.3 Message RAM Representation in Debug/Suspend Mode

In Debug/Suspend mode, the Message RAM will be memory mapped. This allows the external debug unit to access the Message RAM.

**NOTE:** During Debug/Suspend Mode, the Message RAM cannot be accessed via the IFx register sets.

**Figure 27-5. Message RAM Representation in Debug/Suspend Mode**

| Bit            | 31<br>15  | 30<br>14 | 29<br>13 | 28<br>12   | 27<br>11 | 26<br>10 | 25<br>9 | 24<br>8 | 23<br>7 | 22<br>6  | 21<br>5 | 20<br>4 | 19<br>3     | 18<br>2  | 17<br>1 | 16<br>0 |

### 27.5.4 Message RAM Representation in Direct Access Mode

When the RDA bit in Test Register is set while the DCAN module is in Test Mode (Test bit in CAN control register is set), the CPU has direct access to the Message RAM. Due to the 32-bit bus structure, the RAM is split into word lines to support this feature. The CPU has access to one word line at a time only.

In RAM Direct Access mode, the RAM is represented by a continuous memory space within the address frame of the DCAN module, starting at the Message RAM base address.

**NOTE:** During Direct Access Mode, the Message RAM cannot be accessed via the IFx register sets. Before entering RDA mode, it must be ensured that the Init bit is set to avoid any conflicts with the message handler accessing the message RAM.

Any read or write to the RAM addresses for RamDirectAccess during normal operation mode (TestMode bit or RDA bit is not set) will be ignored.

Writes to Reserved bits have no effect.

**Figure 27-6. Message RAM Representation in RAM Direct Access Mode**

| Bit            | 31<br>15    | 30<br>14 | 29<br>13 | 28<br>12 | 27<br>11 | 26<br>10 | 25<br>9 | 24<br>8 | 23<br>7 | 22<br>6 | 21<br>5 | 20<br>4 | 19<br>3  | 18<br>2 | 17<br>1 | 16<br>0 |     |        |  |
|----------------|-------------|----------|----------|----------|----------|----------|---------|---------|---------|---------|---------|---------|----------|---------|---------|---------|-----|--------|--|
| MsgAddr + 0x00 | Data 4      |          |          |          |          |          |         |         | Data 5  |         |         |         |          |         |         |         |     |        |  |
|                | Data 6      |          |          |          |          |          |         |         | Data 7  |         |         |         |          |         |         |         |     |        |  |
| MsgAddr + 0x04 | Data 0      |          |          |          |          |          |         |         | Data 1  |         |         |         |          |         |         |         |     |        |  |
|                | Data 2      |          |          |          |          |          |         |         | Data 3  |         |         |         |          |         |         |         |     |        |  |
| MsgAddr + 0x08 | ID[27:12]   |          |          |          |          |          |         |         |         |         |         |         |          |         |         |         |     |        |  |
|                | ID[11:0]    |          |          |          |          |          |         |         |         |         |         |         | DLC[3:0] |         |         |         |     |        |  |
| MsgAddr + 0x0C | Msk[28:13]  |          |          |          |          |          |         |         |         |         |         |         |          |         |         |         |     |        |  |
|                | Msk[12:0]   |          |          |          |          |          |         |         |         |         |         |         |          |         | Xtd     |         | Dir | ID[28] |  |
| MsgAddr + 0x10 | Reserved    |          |          |          |          |          |         |         |         |         |         |         |          |         |         |         |     |        |  |
|                | Parity[3:0] |          |          |          | Reserved |          |         |         | MsgLst  |         | UMask   |         | TxIE     | RxTE    |         | RmtEn   | EOB | MXtd   |  |

## 27.6 Message Interface Register Sets

Accesses to the Message RAM are performed via the Interface Register sets.

1. Interface Register 1 and 2
2. Interface Register 3

The third Interface Register set IF3 can be configured to automatically receive control and user data from the Message RAM when a message object has been updated after reception of a CAN message. The CPU does not need to initiate the transfer from Message RAM to IF3 Register set.

The Message Handler avoids potential conflicts between concurrent accesses to Message RAM and CAN frame reception/transmission.

There are two modes where the Message RAM can be directly accessed by the CPU:

1. In Debug/Suspend mode (see [Section 27.5.3](#))
2. In RAM Direct Access (RDA) mode (see [Section 27.5.4](#))

For the Message RAM Base address, please refer to the device datasheet.

A complete message object (see [Section 27.5.1](#)) or parts of the message object may be transferred between the Message RAM and the IF1/IF2 Register set (see [Section 27.17.19](#)) in one single transfer.

### 27.6.1 Message Interface Register Sets 1 and 2

The Interface Register sets IF1 and IF2 provide indirect read/write access from the CPU to the Message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

**Table 27-4. Message Interface Register Sets 1 and 2**

| Address<br>[CAN Base +] | IF1 Register Set  |    |                     | Address<br>[CAN Base +] | IF2 Register Set  |    |                     |
|-------------------------|-------------------|----|---------------------|-------------------------|-------------------|----|---------------------|
|                         | 31                | 16 | 15 0                |                         | 31                | 16 | 15 0                |
| 0x100                   | IF1 Command Mask  |    | IF1 Command Request | 0x120                   | IF2 Command Mask  |    | IF2 Command Request |
| 0x104                   | IF1 Mask 2        |    | IF1 Mask 1          | 0x124                   | IF2 Mask 2        |    | IF2 Mask 1          |
| 0x108                   | IF1 Arbitration 2 |    | IF1 Arbitration 1   | 0x128                   | IF2 Arbitration 2 |    | IF2 Arbitration 1   |
| 0x10C                   | Rsvd              |    | IF1 Message Control | 0x12C                   | Rsvd              |    | IF2 Message Control |
| 0x110                   | IF1 Data A 2      |    | IF1 Data A 1        | 0x130                   | IF2 Data A 2      |    | IF2 Data A 1        |
| 0x114                   | IF1 Data B 2      |    | IF1 Data B 1        | 0x134                   | IF2 Data B 2      |    | IF2 Data B 1        |

## 27.6.2 Using Message Interface Register Sets 1 and 2

The Command Register addresses the desired message object in the Message RAM and specifies whether a complete message object or only parts should be transferred. The data transfer is initiated by writing the message number to the bits [7:0] of the Command Register.

When the CPU initiates a data transfer between the IF1/IF2 Registers and Message RAM, the Message Handler sets the Busy bit in the respective Command Register to '1'. After the transfer has completed, the Busy bit is set back to '0' (see [Figure 27-7](#)).

**Figure 27-7. Data Transfer Between IF1 / IF2 Registers and Message RAM**

### 27.6.3 Message Interface Register 3

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU. The intention of this feature of IF3 is to provide an interface for the DMA to read packets efficiently.

**Table 27-5. Message Interface Register 3**

| Address<br>[CAN Base +] | IF3 Register Set    |                     |
|-------------------------|---------------------|---------------------|
|                         | 31                  | 16 15 0             |
| 0x140                   | reserved            | IF3 Observation     |
| 0x144                   | IF3 Mask 2          | IF3 Mask 1          |
| 0x148                   | IF3 Arbitration 2   | IF3 Arbitration 1   |
| 0x14C                   | reserved            | IF3 Message Control |
| 0x150                   | IF3 Data A 2        | IF3 Data A 1        |
| 0x154                   | IF3 Data B 2        | IF3 Data B 1        |
| ...                     |                     |                     |
| 0x160                   | IF3 Update Enable 2 | IF3 Update Enable 1 |
| 0x164                   | IF3 Update Enable 4 | IF3 Update Enable 3 |
| 0x168                   | IF3 Update Enable 6 | IF3 Update Enable 5 |
| 0x16C                   | IF3 Update Enable 8 | IF3 Update Enable 7 |

The automatic update functionality can be programmed for each message object (see IF3 Update Enable Register, [Section 27.17.28](#)).

All valid message objects in Message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register. If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA request is generated. The DMA request stays active until first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DE3 in CAN Control register. Please refer to the device datasheet to find out if this DMA source is available.

---

**NOTE:** The IF3 register set can not be used for transferring data into message objects.

---

## 27.7 Message Object Configurations

This section describes the possible message object configurations for CAN communication.

### 27.7.1 Configuration of a Transmit Object for Data Frames

Figure 27-8 shows how a Transmit Object can be initialized.

**Figure 27-8. Initialization of a Transmit Object**

| MsgVal | Arb   | Data  | Mask  | EoB | Dir | NewDat | MsgLst | RxIE | TxIE  | IntPnd | RmtEn | TxRqst |
|--------|-------|-------|-------|-----|-----|--------|--------|------|-------|--------|-------|--------|
| 1      | appl. | appl. | appl. | 1   | 1   | 0      | 0      | 0    | appl. | 0      | appl. | 0      |

The Arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit Identifier (Standard Frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.

The Data Registers (DLC[3:0] and Data0-7) are given by the application, TxRqst and RmtEn should not be set before the data is valid.

If the TxIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received Remote Frame will cause the TxRqst bit to be set; the Remote Frame will autonomously be answered by a Data Frame.

The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = '1') to allow groups of Remote Frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see [Section 27.8.8](#). Identifier masking must be disabled (UMask = '0') if no Remote Frames are allowed to set the TxRqst bit (RmtEn = '0').

### 27.7.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure Transmit Objects for the transmission of Remote Frames. Setting TxRqst for a Receive Object will cause the transmission of a Remote Frame with the same identifier as the Data Frame for which this receive Object is configured.

### 27.7.3 Configuration of a Single Receive Object for Data Frames

Figure 27-9 shows how a Receive Object for Data Frames can be initialized.

**Figure 27-9. Initialization of a Single Receive Object for Data Frames**

| MsgVal | Arb   | Data  | Mask  | EoB | Dir | NewDat | MsgLst | RxIE  | TxIE | IntPnd | RmtEn | TxRqst |
|--------|-------|-------|-------|-----|-----|--------|--------|-------|------|--------|-------|--------|
| 1      | appl. | appl. | appl. | 1   | 0   | 0      | 0      | appl. | 0    | 0      | 0     | 0      |

The Arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (Standard Frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a Data Frame with an 11-bit Identifier is received, ID[17:0] will be set to '0'.

The Data Length Code (DLC[3:0]) is given by the application. When the Message Handler stores a Data Frame in the message object, it will store the received Data Length Code and eight data bytes. If the Data Length Code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.

The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = '1') to allow groups of Data Frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the Mask bits are set to "don't care", the corresponding bits of the Arbitration Register will be overwritten by the bits of the stored Data Frame.

If the RxIE bit is set, the IntPnd bit will be set when a received Data Frame is accepted and stored in the message object.

If the TxRqst bit is set, the transmission of a Remote Frame with the same identifier as actually stored in the Arbitration bits will be triggered. The content of the Arbitration bits may change if the Mask bits are used (UMask = '1') for acceptance filtering.

## 27.7.4 Configuration of a Single Receive Object for Remote Frames

Figure 27-10 shows how a Receive Object for Remote Frames can be initialized.

**Figure 27-10. Initialization of a Single Receive Object for Remote Frames**

| MsgVal | Arb   | Data  | Mask  | EoB | Dir | NewDat | MsgLst | RxIE  | TxIE | IntPnd | RmtEn | TxRqst |
|--------|-------|-------|-------|-----|-----|--------|--------|-------|------|--------|-------|--------|
| 1      | appl. | appl. | appl. | 1   | 1   | 0      | 0      | appl. | 0    | 0      | 0     | 0      |

Receive Objects for Remote Frames may be used to monitor Remote Frames on the CAN bus. The Remote Frame stored in the Receive Object will not trigger the transmission of a Data Frame. Receive Objects for Remote Frames may be expanded to a FIFO buffer, see [Section 27.7.5](#).

UMask must be set to '1'. The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to "must-match" or to "don't care", to allow groups of Remote Frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see [Section 27.8.8](#).

The Arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received Remote Frames. If some bits of the Mask bits are set to "don't care", the corresponding bits of the Arbitration bits will be overwritten by the bits of the stored Remote Frame. If an 11-bit Identifier (Standard Frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a Remote Frame with an 11-bit Identifier is received, ID[17:0] will be set to '0'.

The Data Length Code (DLC[3:0]) may be given by the application. When the Message Handler stores a Remote Frame in the message object, it will store the received Data Length Code. The data bytes of the message object will remain unchanged.

If the RxIE bit is set, the IntPnd bit will be set when a received Remote Frame is accepted and stored in the message object.

## 27.7.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of Receive Objects belonging to a FIFO Buffer is the same as the configuration of a single Receive Object.

To concatenate multiple message objects to a FIFO Buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO Buffer. The EoB bit of all message objects of a FIFO Buffer except the last one have to be programmed to zero. The EoB bits of the last message object of a FIFO Buffer is set to one, configuring it as the end of the block.

## 27.7.6 Reconfiguration of Message Objects for the Reception of Frames

A message object with Dir = '0' is configured for the reception of data frames, with Dir = '1' AND Umask = '1' AND RmtEn = '0' it is configured for the reception of remote frames.

It is necessary to reset MsgVal to not valid before changing any of the following configuration and control bits: ID[28:0], Xtd, Dir, DLC[3:0], RxIE, TxIE, RmtEn, EoB, Umask, Msk[28:0], MXtd, and MDir.

These parts of a message object may be changed without clearing MsgVal: Data[7:0], TxRqst, NewDat, MsgLst, and IntPnd.

## 27.7.7 Reconfiguration of Message Objects for the Transmission of Frames

A message object with Dir = '1' AND (Umask = '0' OR RmtEn = '1') is configured for the transmission of data frames.

It is necessary to reset MsgVal to not valid before changing any of the following configuration and control bits: Dir, RxIE, TxIE, RmtEn, EoB, Umask, Msk[28:0], MXtd, and MDir.

These parts of a message object may be changed without clearing MsgVal: ID[28:0], Xtd, DLC[3:0], Data[7:0], TxRqst, NewDat, MsgLst, and IntPnd.

## 27.8 Message Handling

When initialization is finished, the DCAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects.

The application has to update the data of the messages to be transmitted and enable and request their transmission. The transmission is requested automatically when a matching Remote Frame is received.

The application may read messages which are received and accepted. Messages that are not read before the next messages is accepted for the same message object will be overwritten.

Messages may be read based on interrupts or by polling.

### 27.8.1 Message Handler Overview

The Message Handler state machine controls the data transfer between the Rx/Tx Shift Register of the CAN Core and the Message RAM. It performs the following tasks:

- Data Transfer from Message RAM to CAN Core (messages to be transmitted).
- Data Transfer from CAN Core to the Message RAM (received messages).
- Data Transfer from CAN Core to the Acceptance Filtering unit.
- Scanning of Message RAM for a matching message object (acceptance filtering).
- Scanning the same message object after being changed by IF1/IF2 registers when priority is same or higher as message the object found by last scanning.
- Handling of TxRqst flags.
- Handling of interrupt flags.

The Message Handler registers contains status flags of all message objects grouped into the following topics:

- Transmission Request flags
- New Data flags
- Interrupt Pending Flags
- Message Valid Registers

Instead of collecting the listed status information of each message object via IFx registers separately, these Message Handler registers provides a fast and easy way to get an overview (for example, about all pending transmission requests).

All Message Handler registers are read-only.

### 27.8.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while the last implemented message object has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object, so messages with the highest priority can be placed in the message objects with the lowest numbers.

The acceptance filtering for received Data Frames or Remote Frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher Message Number. The last message object may be configured to accept any Data Frame or Remote Frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

### 27.8.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN Core is ready for loading and if there is no data transfer between the IFx Registers and Message RAM, the d bits in the Message Valid Register and the TxRqst bits in the Transmission Request Register are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the Message Handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the DCAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If Automatic Retransmission mode is disabled by setting the DAR bit in the CAN Control Register, the behavior of bits TxRqst and NewDat in the Message Control Register of the Interface Register set is as follows:

- When a transmission starts, the TxRqst bit of the respective Interface Register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error) bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received Remote Frames do not require a Receive Object. They will automatically trigger the transmission of a Data Frame, if in the matching Transmit Object the RmtEn bit is set.

### 27.8.4 Updating a Transmit Object

The CPU may update the data bytes of a Transmit Object any time via the IF1/IF2 Interface Registers, neither d nor TxRqst have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A Register or IF1/IF2 Data B Register have to be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the IF1/IF2 Data Register or the message object is transferred to the IF1/IF2 Data Register before the CPU writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the Command Register and then the number of the message object is written to bits [7:0] of the Command Register, concurrently updating the data bytes and setting TxRqst with NewDat.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details, see [Section 27.8.3](#).

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

### 27.8.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the Transmit Objects may be managed dynamically. The CPU can write the whole message (Arbitration, Control, and Data) into the Interface Register. The bits [23:16] of the Command Register can be set to 0xB7 for the transfer of the whole message object content into the message object. Before changing the configuration of a message object, MsgVal has to be reset (see [Section 27.7.7](#)).

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however it will not be repeated if it is disturbed.

To only update the data bytes of a message to be transmitted, bits [23:16] of the Command Register should be set to 0x87.

---

**NOTE:** After the update of the Transmit Object, the Interface Register set will contain a copy of the actual contents of the object, including the part that had not been updated.

---

### 27.8.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message is completely shifted into the shift register of the CAN Core, the Message Handler starts to scan of the Message RAM for a matching valid message object:

- The Acceptance Filtering unit is loaded with the arbitration bits from the CAN Core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of Message Object 1 are loaded into the Acceptance Filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the Message RAM is reached.
- If a match occurs, the scanning is stopped and the Message Handler proceeds depending on the type of the frame (Data Frame or Remote Frame) received.

### 27.8.7 Reception of Data Frames

The Message Handler stores the message from the CAN Core shift register into the respective message object in the Message RAM. Not only the data bytes, but all arbitration bits and the Data Length Code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the CPU) has been received. The CPU should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (supposedly not seen by the CPU) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the Interrupt Register to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a Remote Frame, while the requested Data Frame has just been received.

### 27.8.8 Reception of Remote Frames

When a Remote Frame is received, three different configurations of the matching message object have to be considered:

1. Dir = '1' (direction = transmit), RmtEn = '1', UMask = '1' or '0' The TxRqst bit of this message object is set at the reception of a matching Remote Frame. The rest of the message object remains unchanged.
2. Dir = '1' (direction = transmit), RmtEn = '0', UMask = '0' The Remote Frame is ignored, this message object remains unchanged.
3. Dir = '1' (direction = transmit), RmtEn = '0', UMask = '1' The Remote Frame is treated similar to a received Data Frame. At the reception of a matching Remote Frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the Message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged.

### 27.8.9 Reading Received Messages

The CPU may read a received message any time via the IFx Interface Registers, the data consistency is guaranteed by the Message Handler state machine.

Typically the CPU will write first 0x7F to bits [23:16] and then the number of the message object to bits [7:0] of the Command Register. That combination will transfer the whole received message from the Message RAM into the Interface Register set. Additionally, the bits NewDat and IntPnd are cleared in the Message RAM (not in the Interface Register set). The values of these bits in the Message Control Register always reflect the status before resetting the bits.

If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message have been received since the last time when this message object was read. MsgLst will not be automatically reset.

### 27.8.10 Requesting New Data for a Receive Object

By means of a Remote Frame, the CPU may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a Remote Frame with the receive object's identifier. This Remote Frame triggers the other CAN node to start the transmission of the matching Data Frame. If the matching Data Frame is received before the Remote Frame could be transmitted, the TxRqst bit is automatically reset.

Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the Command Register.

### 27.8.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO Buffers. Each FIFO Buffer configured to store received messages with a particular (group of) Identifier(s). Arbitration and Mask Registers of the FIFO Buffer's message objects are identical. The EoB (End of Buffer) bits of all but the last of the FIFO Buffer's message objects are '0', in the last one the EoB bit is '1'.

Received messages with identifiers matching to a FIFO Buffer are stored into a message object of this FIFO Buffer, starting with the message object with the lowest message number.

When a message is stored into a message object of a FIFO Buffer the NewDat bit of this message object is set. By setting NewDat while EoB is '0' the message object is locked for further write accesses by the Message Handler until the CPU has cleared the NewDat bit.

Messages are stored into a FIFO Buffer until the last message object of this FIFO Buffer is reached. If none of the preceding message objects is released by writing NewDat to '0', all further messages for this FIFO Buffer will be written into the last message object of the FIFO Buffer (EoB = '1') and therefore overwrite previous messages in this message object.

### 27.8.12 Reading from a FIFO Buffer

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO Buffer before the application program is required (in order to avoid the loss of data) to empty the buffer.

A FIFO Buffer of length N will store N-1 plus the last received message since last time it was cleared.

A FIFO Buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in [Figure 27-11](#).

---

**NOTE:** All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise true FIFO functionality can not be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

---

Reading from a FIFO Buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

**Figure 27-11. CPU Handling of a FIFO Buffer (Interrupt Driven)**

## 27.9 CAN Message Transfer

Once the DCAN is initialized and Initbit is reset to zero, the CAN Core synchronizes itself to the CAN bus and is ready for message transfer as per the configured message objects.

The CPU may enable the interrupt lines (setting IE0 and IE1 to '1') at the same time when it clears Init and CCE. The status interrupts EIE and SIE may be enabled simultaneously.

The CAN communication can be carried out in any of the following two modes:

1. Interrupt mode
2. Polling mode.

The Interrupt Register points to those message objects with IntPnd = '1'. It is updated even if the interrupt lines to the CPU are disabled (IE0 / IE1 are zero).

The CPU may poll all Message Object's NewDat and TxRqst bits in parallel from the NewData X Registers and the Transmission Request X Registers. Polling can be made easier if all Transmit Objects are grouped at the low numbers, all Receive Objects are grouped at the high numbers.

Received messages are stored into their appropriate message objects if they pass acceptance filtering.

The whole message (including all arbitration bits, DLC and up to eight data bytes) is stored into the message object. As a consequence, when the identifier mask is used, the arbitration bits which are masked to "don't care" may change in the message object when a received message is stored.

The CPU may read or write each message at any time via the Interface Registers, as the Message Handler guarantees data consistency in case of concurrent accesses (for reconfiguration, see [Section 27.7.6](#))

If a permanent message object (arbitration and control bits set up during configuration and leaving unchanged for multiple CAN transfers) exists for the message, it is possible to only update the data bytes.

If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority.

Messages may be updated or set to not valid at any time, even if a requested transmission is still pending (for reconfiguration, see [Section 27.7.7](#)). However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

### 27.9.1 Automatic Retransmission

According to the CAN Specification (ISO11898), the DCAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting bit DAR (Disable Automatic Retransmission) in CAN Control Register. Further details to this mode are provided in [Section 27.8.3](#).

### 27.9.2 Auto-Bus-On

Per default, after the DCAN has entered Bus-Off state, the CPU can start a Bus-Off-Recovery sequence by resetting Init bit. If this is not done, the module will stay in Bus-Off state.

The DCAN provides an automatic Auto-Bus-On feature which is enabled by bit ABO in CAN Control Register. If set, the DCAN will automatically start the Bus-Off-Recovery sequence. The sequence can be delayed by a user-defined number of VCLK cycles which can be defined in Auto-Bus-On Time Register.

**NOTE:** If the DCAN goes Bus-Off due to massive occurrence of CAN bus errors, it stops all bus activities and automatically sets the Init bit. Once the Init bit has been reset by the CPU or due to the Auto-Bus-On feature, the device will wait for 129 occurrences of Bus Idle (equal to  $129 \times 11$  consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

## 27.10 Interrupt Functionality

Interrupts can be generated on two interrupt lines:

1. DCAN0INT line
2. DCAN1INT line

These lines can be enabled by setting IE0 and IE1 bits respectively in CAN Control Register.

The DCAN provides three groups of interrupt sources: Message Object Interrupts, Status Change Interrupts and Error Interrupts (see [Figure 27-12](#) and [Figure 27-13](#)).

The source of an interrupt can be determined by the interrupt identifiers Int0ID / Int1ID in the Interrupt Register (see [Section 27.17.5](#)). When no interrupt is pending, the register will hold the value zero.

Each interrupt line remains active until the dedicated field in the Interrupt Register DCAN INT (Int0ID / Int1ID) again reach zero (this means the cause of the interrupt is reset), or until IE0 / IE1 are reset.

The value 0x8000 in the Int0ID field indicates that an interrupt is pending because the CAN Core has updated (not necessarily changed) the Error and Status Register (Error Interrupt or Status Interrupt). This interrupt has the highest priority. The CPU can update (reset) the status bits WakeUpPnd, RxOk, TxOk and LEC by reading the Error and Status Register DCAN ES, but a write access of the CPU will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects, Int0ID resp. Int1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority, the last message object has the lowest priority.

An interrupt service routine which reads the message that is the source of the interrupt, may read the message and reset the message object's IntPnd at the same time (ClrIntPnd bit in the IF1/IF2 Command Register). When IntPnd is cleared, the Interrupt Register will point to the next message object with a pending interrupt.

### 27.10.1 Message Object Interrupts

Message Object interrupts are generated by events from the message objects. They are controlled by the flags IntPND, TxIE and RxIE, which are described in [Section 27.5.1](#).

Message Object interrupts can be routed to either DCAN0INT or DCAN1INT line, controlled by the Interrupt Multiplexer Register (see [Section 27.17.17](#)).

### 27.10.2 Status Change Interrupts

The events WakeUpPnd, RxOk, TxOk and LEC in Error and Status Register (DCAN ES) belong to the Status Change Interrupts. The Status Change Interrupt group can be enabled by bit in CAN Control Register.

If SIE is set, a Status Change Interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the Message RAM configuration.

Status Change interrupts can only be routed to interrupt line DCAN0INT which has to be enabled by setting IE0 in the CAN Control Register.

**NOTE:** Reading the Error and Status Register will clear the WakeUpPnd flag. If in global power down mode, the WakeUpPnd flag is cleared by such a read access before the DCAN module has been waken up by the system, the DCAN may re-assert the WakeUpPnd flag, and a second interrupt may occur (additional information can be found in [Section 27.11.2](#)).

### 27.10.3 Error Interrupts

The events PER, BOff and EWarn (monitored in Error and Status Register, DCAN ES) belong to the Error Interrupts. The Error Interrupt group can be enabled by setting bit EIE in CAN Control Register.

Error interrupts can only be routed to interrupt line DCAN0INT which has to be enabled by setting IE0 in the CAN Control Register.

**Figure 27-12. CAN Interrupt Topology 1**

Figure 27-13. CAN Interrupt Topology 2

## 27.11 Global Power Down Mode

The device architecture supports a centralized global power down control over the peripheral modules through the Peripheral Central Resource (PCR) module.

### 27.11.1 Entering Global Power Down Mode

The global power down mode for the DCAN is requested by setting the appropriate Peripheral Power Down Set bit (**PSPWRDWNSETx**) in the PCR module.

The DCAN then finishes all transmit requests of the message objects. When all requests are done, the DCAN waits until a bus idle state is recognized. Then it will automatically set the Initbit to indicate that the global power down mode has been entered.

### 27.11.2 Wakeup From Global Power Down Mode

When the DCAN module is in global power down mode, a CAN bus activity detection circuit exists, which can be active, if enabled. If this circuit is active, on occurrence of a dominant CAN bus level, the DCAN will set the **WakeUpPnd** bit in Error and Status Register (DCAN ES).

If Status Interrupts are enabled, also an interrupt will be generated. This interrupt could be used by the application to wakeup the DCAN. For this, the application needs to set the appropriate Peripheral Power Down Clear bit (**PSPWRDWNCLR<sub>x</sub>**) in the PCR module, and to clear the Init bit in CAN Control Register.

After the Init bit has been cleared, the DCAN module waits until it detects 11 consecutive recessive bits on the CAN\_RX pin and then goes Bus-Active again.

**NOTE:** The CAN transceiver circuit has to stay active during CAN bus activity detection. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down mode is lost.

## 27.12 Local Power Down Mode

Besides the centralized power down mechanism controlled by the PCR module (global power down, see [Section 27.15](#)), the DCAN supports a local power down mode which can be controlled within the DCAN control registers.

### 27.12.1 Entering Local Power Down Mode

The local power down mode is requested by setting the PDRbit in CAN Control Register.

The DCAN then finishes all transmit requests of the message objects. When all requests are done, DCAN waits until a bus idle state is recognized. Then it will automatically set the Initbit in CAN Control Register to prevent any further CAN transfers, and it will also set the PDA bit in CAN Error and Status Register. With setting the PDA bits, the DCAN module indicates that the local power down mode has been entered.

During local power down mode, the internal clocks of the DCAN module are turned off, but there is a wake up logic (see [Section 27.12.2](#)) which can be active, if enabled. Also the actual contents of the control registers can be read back.

---

**NOTE:** In local low power mode, the application should not clear the Init bit while PDR is set. If there are any messages in the Message RAM configured as to be transmitted and the application resets the init bit, these messages may be sent.

---

### 27.12.2 Wakeup From Local Power Down

There are two ways to wake up the DCAN from local power down mode:

1. The application could wake up the DCAN module manually by clearing the PDR bit and then clearing the Init bit in CAN Control Register.
2. Alternatively, a CAN bus activity detection circuit can be activated by setting the wake up on bus activity bit (WUBA) in CAN Control Register. If this circuit is active, on occurrence of a dominant CAN bus level, the DCAN will automatically start the wake up sequence. It will clear the PDR bit in CAN Control Register and also clear the PDA bit in Error and Status Register. The WakeUpPnd bit in CAN Error and Status Register will be set. If Status Interrupts are enabled, also an interrupt will be generated. Finally the Init bit in CAN control register will be cleared.

After the Init bit has been cleared, the module waits until it detects 11 consecutive recessive bits on the CAN\_RX pin and then goes Bus-Active again.

---

**NOTE:** The CAN transceiver circuit has to stay active while CAN bus observation. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, is lost.

---

[Figure 27-14](#) shows a flow diagram about entering and leaving local power down mode.

## 27.13 GPIO support

The CAN\_RX and CAN\_TX pins of each DCAN module can be used as general purpose IO pins, if CAN functionality is not needed. This function is controlled by the CAN TX IO Control register (see [Section 27.17.29](#)) and the CAN RX IO Control register (see [Section 27.17.30](#)).

Figure 27-14. Local Power Down Mode Flow Diagram

## 27.14 Test Modes

The DCAN provides several test modes which are mainly intended for production tests or self test.

For all test modes, Test bit in the CAN Control Register needs to be set to one. This enables write access to the Test Register.

---

**NOTE:** When using any of the Loop Back modes, it must be ensured by software that all message transfers are finished before setting the Init bit to '1'.

---

### 27.14.1 Silent Mode

The Silent Mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (for example, acknowledge bit, overload flag, active error flag). The DCAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, these are internally routed to the CAN Core.

[Figure 27-15](#) shows the connection of signals CAN\_TX and CAN\_RX to the CAN Core in Silent Mode.

Silent Mode can be activated by setting the Silentbit in Test Register to one.

In ISO 11898-1, the Silent Mode is called the Bus Monitoring Mode.

**Figure 27-15. CAN Core in Silent Mode**

## 27.14.2 Loop Back Mode

The Loop Back Mode is mainly intended for hardware self-test functions. In this mode, the CAN Core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN\_RX input pin is disregarded by the CAN Core. Transmitted messages still can be monitored at the CAN\_TX pin.

In order to be independent from external stimulation, the CAN Core ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in Loop Back Mode.

Figure 27-16 shows the connection of signals CAN\_TX and CAN\_RX to the CAN Core in Loop Back Mode.

Loop Back Mode can be activated by setting bit LBackin Test Register to one.

---

**NOTE:** In Loop Back mode, the signal path from CAN Core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN Core are disregarded. For including these into the testing, see External Loop Back mode (Section 27.14.3).

---

**Figure 27-16. CAN Core in Loop Back Mode**

### 27.14.3 External Loop Back Mode

The External Loop Back Mode is similar to the Loop Back Mode, however it includes the signal path from CAN Core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN Core. When External Loop Back Mode is selected, the input of the CAN core is connected to the input buffer of the Tx pin.

With this configuration, the Tx pin IO circuit can be tested.

External Loop Back Mode can be activated by setting bit **ExL** in Test Register to one.

[Figure 27-17](#) shows the connection of signals CAN\_TX and CAN\_RX to the CAN Core in External Loop Back Mode.

---

**NOTE:** When Loop Back Mode is active (LBack bit set), the ExL bit will be ignored.

---

**Figure 27-17. CAN Core in External Loop Back Mode**

#### 27.14.4 Loop Back Combined with Silent Mode

It is also possible to combine Loop Back Mode and Silent Mode by setting bits LBackand Silent at the same time. This mode can be used for a “Hot Selftest”, that is, the DCAN hardware can be tested without affecting the CAN network. In this mode, the CAN\_RX pin is disconnected from the CAN Core and no dominant bits will be sent on the CAN\_TX pin.

Figure 27-18 shows the connection of the signals CAN\_TX and CAN\_RX to the CAN Core in case of the combination of Loop Back Mode with Silent Mode.

**Figure 27-18. CAN Core in Loop Back Combined with Silent Mode**

#### 27.14.5 Software Control of CAN\_TX Pin

Four output functions are available for the CAN transmit pin CAN\_TX. Additionally to its default function (serial data output), the CAN\_TX pin can drive constant dominant or recessive values, or it can drive the CAN Sample Point signal to monitor the CAN Core's bit timing.

Combined with the readable value of the CAN\_RX pin, this can be used to check the physical layer of the CAN bus.

The output mode of pin CAN\_TX is selected by programming the Test Register bits Tx[1:0] as described in [Section 27.17.6](#).

---

**NOTE:** The software control for pin CAN\_TX interferes with CAN protocol functions. For CAN message transfer or any of the test modes Loop Back Mode, External Loop Back Mode or Silent Mode, the CAN\_TX pin should operate in its default functionality.

---

## 27.15 Parity Check Mechanism

The DCAN provides a parity check mechanism to ensure data integrity of Message RAM data. For each word (32 bits) in Message RAM, one parity bit will be calculated. The formation of the different words is according to the Message RAM representation in RDA mode (see [Section 27.5.4](#)).

Parity information is stored in the Message RAM on write accesses and will be checked against the stored parity bit from Message RAM on read accesses.

The parity check functionality can be enabled or disabled by PMD bit field in CAN Control Register.

In case of disabled parity check, the parity bits in message RAM will be left unchanged on write access to data area and no check will be done on read access.

If parity checking is enabled, parity bits will be automatically generated and checked by the DCAN. The parity bits could be read in Debug/Suspend mode (see [Section 27.5.3](#)) or in RDA mode (see [Section 27.5.4](#)). However, direct write access to the parity bits is only possible in this two modes with parity check disabled.

A parity bit will be set, if the modulo-2-sum of the data bits is 1. This definition is equivalent to: The parity bit will be set, if the number of 1 bits in the data is odd.

---

**NOTE:** Parity scheme can be changed via the System module DEV Parity Control Register1 on device basis for all peri RAMs.

---

### 27.15.1 Behavior on Parity Error

On any read access to Message RAM (for example, during start of a CAN frame transmission), the parity of the message object will be checked. If a parity error is detected, the PER bit in Error and Status Register will be set. If error interrupts are enabled, also an interrupt would be generated. In order to avoid the transmission of invalid data over the CAN bus, the d bit of the message object will be reset.

The message object data can be read by the host CPU, independently of parity errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the Parity Error Code register on parity error interrupt.

---

**NOTE:** During RAM initialization, no parity check will be done.

---

### 27.15.2 Parity Testing

Testing the parity mechanism can be done by enabling the bit RDA (RamDirectAccess) and manually writing the parity bits directly to the dedicated RAM locations. With this, data and parity bits could be checked when reading directly from RAM.

---

**NOTE:** If parity check was disabled, the application has to ensure correct parity bit handling in order to prevent parity errors later on when parity check is enabled.

---

## 27.16 Debug/Suspend Mode

The module supports the usage of an external debug unit by providing functions like pausing DCAN activities and making Message RAM content accessible via VBUSP interface.

Before entering debug/suspend mode, the circuit will either wait until a started transmission or reception will be finished and Bus idle state is recognized, or immediately interrupt a current transmission or reception. This is depending on bit IDSin CAN Control Register.

Afterwards, the DCAN enters debug/suspend mode, indicated by InitDbg flag in CAN Control Register.

During Debug/Suspend mode, all DCAN registers can be accessed. Reading reserved bits will return '0'. Writing to reserved bits will have no effect.

Also, the Message RAM will be memory mapped. This allows the external debug unit to read the Message RAM. For the memory organization, see [Section 27.5.3](#).

---

**NOTE:** During Debug/Suspend Mode, the Message RAM cannot be accessed via the IFx register sets.

Writing to control registers in debug/suspend mode may influence the CAN state machine and further message handling.

---

For debug support, the auto clear functionality of the following DCAN registers is disabled:

- \* Error and Status Register (clear of status flags by read)
- \* IF1/IF2 Command Registers (clear of DMAActive flag by r/w)

## 27.17 DCAN Control Registers

[Table 27-6](#) lists the control registers of the DCAN. After hardware reset, the registers of the DCAN hold the values shown in the register descriptions.

Additionally, the Bus-Off state is reset and the CAN\_TX pin is set to recessive (HIGH). The Init bit in the CAN Control Register is set to enable the software initialization. The DCAN will not influence the CAN bus until the CPU resets Init to 0.

**Table 27-6. DCAN Control Registers**

| Offset | Acronym      | Register Description             | Section                          |

**NOTE:** The Bus-Off recovery sequence (see CAN specification) cannot be shortened by setting or resetting Init bit. If the module goes Bus-Off, it will automatically set the Init bit and stop all bus activities.

When the Init bit is cleared by the application again, the module will then wait for 129 occurrences of Bus Idle (129 \* 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

After the Init bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 error code is written to the Error and Status Register, enabling the CPU to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the Bus-Off recovery sequence.

**Table 27-8. Error and Status Register Field Descriptions (continued)**

| Bit | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|-------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | EPass | 0     | Error Passive State                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|     |       | 1     | On CAN Bus error, the DCAN could send active error frames.<br>The CAN Core is in the error passive state as defined in the CAN Specification.                                                                                                                                                                                                                                                                                                                                                |
| 4   | RxOK  | 0     | Received a message successfully                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|     |       | 1     | No message has been successfully received since the last time when this bit was read by the CPU. This bit is never reset by DCAN internal events.<br>A message has been successfully received since the last time when this bit was reset by a read access of the CPU (independent of the result of acceptance filtering). This bit will be reset if Error and Status Register is read.                                                                                                      |
| 3   | TxOK  | 0     | Transmitted a message successfully                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|     |       | 1     | No message has been successfully transmitted since the last time when this bit was read by the CPU. This bit is never reset by DCAN internal events.<br>A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was reset by a read access of the CPU. This bit will be reset if Error and Status Register is read.                                                                                           |
| 2-0 | LEC   |       | Last Error Code                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|     |       |       | The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error.                                                                                                                                                                                                                                                                                                          |
|     |       | 0     | No Error                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|     |       | 1h    | Stuff Error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed.                                                                                                                                                                                                                                                                                                                                                                |
|     |       | 2h    | Form Error: A fixed format part of a received frame has the wrong format.                                                                                                                                                                                                                                                                                                                                                                                                                    |
|     |       | 3h    | Ack Error: The message this CAN Core transmitted was not acknowledged by another node.                                                                                                                                                                                                                                                                                                                                                                                                       |
|     |       | 4h    | Bit1 Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant.                                                                                                                                                                                                                                                                            |
|     |       | 5h    | Bit0 Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). |
|     |       | 6h    | CRC Error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data).                                                                                                                                                                                                                                                                                                                           |
|     |       | 7h    | No CAN bus event was detected since the last time when CPU has read the Error and Status Register. Any read access to the Error and Status Register re-Initializes the LEC to value '7'.                                                                                                                                                                                                                                                                                                     |

Interrupts are generated by bits PER, BOff and EWarn (if EIE bit in CAN Control Register is set) and by bits WakeUpPnd, RxOk, TxOk, and LEC (if SIE bit in CAN Control Register is set). A change of bit EPass will not generate an Interrupt.

**NOTE:** Reading the Error and Status Register clears the WakeUpPnd, PER, RxOk and TxOk bits and set the LEC to value '7'. Additionally, the Status Interrupt value (8000h) in the Interrupt Register will be replaced by the next lower priority interrupt value.

For debug support, the auto clear functionality of Error and Status Register (clear of status flags by read) is disabled when in Debug/Suspend mode.

### 27.17.3 Error Counter Register (DCAN ERRC)

**Figure 27-21. Error Counter Register (DCAN ERRC) [offset = 08h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 27-9. Error Counter Register Field Descriptions**

| Bit   | Field    | Value  | Description                                                                                                                                                                                |
|-------|----------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0      | These bits are always read as 0. Writes have no effect.                                                                                                                                    |
| 15    | RP       | 0<br>1 | Receive Error Passive<br>The Receive Error Counter is below the error passive level.<br>The Receive Error Counter has reached the error passive level as defined in the CAN Specification. |
| 14-8  | REC      | 0-7Fh  | Receive Error Counter. Actual state of the Receive Error Counter. (values from 0 to 255).                                                                                                  |
| 7-0   | TEC      | 0-FFh  | Transmit Error Counter. Actual state of the Transmit Error Counter. (values from 0 to 255).                                                                                                |

## 27.17.4 Bit Timing Register (DCAN BTR)

**Table 27-10. Bit Timing Register Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                        |
|-------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-20 | Reserved | 0     | These bits are always read as 0. Writes have no effect.                                                                                                                                                                                                                                            |
|       | BRPE     | 0-Fh  | Baud Rate Prescaler Extension.<br>Valid programmed values are 0 to 15. By programming BRPE the Baud Rate Prescaler can be extended to values up to 1024.                                                                                                                                           |
| 15    | Reserved | 0     | This bit is always read as 0. Writes have no effect.                                                                                                                                                                                                                                               |
| 14-12 | TSeg2    | 0-7h  | Time segment after the sample point<br>Valid programmed values are 0 to 7. The actual TSeg2 value which is interpreted for the Bit Timing will be the programmed TSeg2 value + 1.                                                                                                                  |
| 11-8  | TSeg1    | 1h-Fh | Time segment before the sample point<br>Valid programmed values are 1 to 15. The actual TSeg1 value interpreted for the Bit Timing will be the programmed TSeg1 value + 1.                                                                                                                         |
| 7-6   | SJW      | 0-3h  | Synchronization Jump Width<br>Valid programmed values are 0 to 3. The actual SJW value interpreted for the Synchronization will be the programmed SJW value + 1.                                                                                                                                   |
| 5-0   | BRP      | 0-3Fh | Baud Rate Prescaler<br>Value by which the CAN_CLK frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid programmed values are 0 to 63. The actual BRP value interpreted for the Bit Timing will be the programmed BRP value + 1. |

**NOTE:** This register is only writable if CCE and Init bits in the CAN Control Register are set.

The CAN bit time may be programmed in the range of 8 to 25 time quanta.

The CAN time quantum may be programmed in the range of 1 to 1024 CAN\_CLK periods.

With a CAN\_CLK of 8 MHz and BRPE = 00, the reset value of 2301h configures the DCAN for a bit rate of 500kBit/s.

For details see [Section 27.3.2.1](#).

| 4     | LBack    | 0<br>1              | Loop Back Mode<br>Disabled<br>Enabled                                                                                                                                                                           |
| 3     | Silent   | 0<br>1              | Silent Mode<br>Disabled<br>Enabled                                                                                                                                                                              |
| 2-0   | Reserved | 0                   | These bits are always read as 0. Writes have no effect.                                                                                                                                                         |

For all test modes, the Test bit in CAN Control Register needs to be set to one. If Test bit is set, the RDA, EXL, Tx1, Tx0, LBack and Silent bits are writable. Bit Rx monitors the state of pin CAN\_RX and therefore is only readable. All Test Register functions are disabled when Test bit is cleared.

**NOTE:** The Test Register is only writable if Test bit in CAN Control Register is set.

Setting Tx[1:0] other than '00' will disturb message transfer.

When the internal loop back mode is active (bit LBack is set), bit EXL will be ignored.

### 27.17.7 Parity Error Code Register (DCAN PERR)

**Figure 27-25. Parity Error Code Register (DCAN PERR) [offset = 1Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; U = Undefined

**Table 27-13. Parity Error Code Register Field Descriptions**

| Bit   | Field          | Value  | Description                                                                                                                                                                                        |
|-------|----------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-11 | Reserved       | 0      | These bits are always read as 0. Writes have no effect.                                                                                                                                            |
| 10-8  | Word Number    | 1h-5h  | Word number where parity error has been detected<br>RDA word number (1 to 5) of the message object (according to the Message RAM representation in RDA mode, see <a href="#">Section 27.5.4</a> ). |
| 7-0   | Message Number | 1h-80h | Message object number where parity error has been detected                                                                                                                                         |

If a parity error is detected, the PER flag will be set in the Error and Status Register. This bit is not reset by the parity check mechanism; it must be reset by reading the Error and Status Register.

In addition to the PER flag, the Parity Error Code Register will indicate the memory area where the parity error has been detected (message number and word number).

If more than one word with a parity error was detected, the highest word number with a parity error will be displayed.

After a parity error has been detected, the register will hold the last error code until power is removed.

### 27.17.8 Auto-Bus-On Time Register (DCAN ABOTR)

| 31-0 | ABO Time | 0-FFFF FFFFh | <p>Number of VBUS clock cycles before a Bus-Off recovery sequence is started by clearing the Init bit . This function has to be enabled by setting bit ABO in CAN Control Register.</p> <p>The Auto-Bus-On timer is realized by a 32-bit counter which starts to count down to zero when the module goes Bus-Off.</p> <p>The counter will be reloaded with the preload value of the ABO Time register after this phase.</p> |

**NOTE:** On write access to the CAN Control register while Auto-Bus-On timer is running, the Auto-Bus-On procedure will be aborted.

During Debug/Suspend mode, running Auto-Bus-On timer will be paused.

### 27.17.9 Transmission Request X Register (DCAN TXRQ X)

With the Transmission Request X Register, the CPU can detect if one or more bits in the different Transmission Request Registers are set. Each register bit represents a group of eight message objects. If at least one of the TxRqst bits of these message objects are set, the corresponding bit in the Transmission Request X Register will be set.

**Figure 27-27. Transmission Request X Register (DCAN TXRQ X) [offset = 84h]**

#### Example 1

Bit 0 of the Transmission Request X Register represents byte 0 of the Transmission Request 1 Register. If one or more bits in this byte are set, bit 0 of the Transmission Request X Register will be set.

### 27.17.10 Transmission Request Registers (DCAN TXRQ12 to DCAN TXRQ78)

These registers hold the TxRqst bits of the implemented message objects. By reading out these bits, the CPU can check for pending transmission requests. The TxRqst bit in a specific message object can be set/reset by the CPU via the IF1/IF2 Message Interface Registers, or by the Message Handler after reception of a remote frame or after a successful transmission.

**Table 27-15. Transmission Request Registers Field Descriptions**

| Bit  | Name         | Value | Description                                                               |
|------|--------------|-------|---------------------------------------------------------------------------|
| 31-0 | TxRqs[128:1] |       | Transmission Request Bits (for all message objects)                       |
|      |              | 0     | No transmission has been requested for this message object.               |
|      |              | 1     | The transmission of this message object is requested and is not yet done. |

### 27.17.11 New Data X Register (DCAN NWDAT X)

With the New Data X Register, the CPU can detect if one or more bits in the different New Data Registers are set. Each register bit represents a group of eight message objects. If at least one of the NewDat bits of these message objects are set, the corresponding bit in the New Data X Register will be set.

**Figure 27-32. New Data X Register (DCAN NWDAT X) [offset = 98h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

#### Equation 1

Bit 0 of the New Data X Register represents byte 0 of the New Data 1 Register. If one or more bits in this byte are set, bit 0 of the New Data X Register will be set.

### 27.17.12 New Data Registers (DCAN NWDAT12 to DCAN NWDAT78)

These registers hold the NewDat bits of the implemented message objects. By reading out these bits, the CPU can check for new data in the message objects. The NewDat bit of a specific message object can be set/reset by the CPU via the IF1/IF2 Interface Register sets, or by the Message Handler after reception of a data frame or after a successful transmission.

| Bit  | Name          | Value | Description                                                                                                                                                                                            |
|------|---------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | NewDat[128:1] | 0     | New Data Bits (for all message objects)<br>No new data has been written into the data portion of this message object by the Message Handler since the last time when this flag was cleared by the CPU. |
|      |               | 1     | The Message Handler or the CPU has written new data into the data portion of this message object.                                                                                                      |

### 27.17.13 Interrupt Pending X Register (DCAN INTPND X)

With the Interrupt Pending X Register, the CPU can detect if one or more bits in the different Interrupt Pending Registers are set. Each bit of this register represents a group of eight message objects. If at least one of the IntPnd bits of these message objects are set, the corresponding bit in the Interrupt Pending X Register will be set.

**Figure 27-37. Interrupt Pending X Register (DCAN INTPND X) [offset = ACh]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

#### Example 2

Bit 0 of the Interrupt Pending X Register represents byte 0 of the Interrupt Pending 1 Register. If one or more bits in this byte are set, bit 0 of the Interrupt Pending X Register will be set.

### 27.17.14 Interrupt Pending Registers (DCAN INTPND12 to DCAN INTPND78)

These registers hold the IntPnd bits of the implemented message objects. By reading out these bits, the CPU can check for pending interrupts in the message objects. The IntPnd bit of a specific message object can be set/reset by the CPU via the IF1/IF2 Interface Register sets, or by the Message Handler after a reception or a successful transmission.

**Figure 27-38. Interrupt Pending 12 Register [offset = B0h]**

**Table 27-17. Interrupt Pending Registers Field Descriptions**

| Bit  | Name          | Value | Description                                            |
|------|---------------|-------|--------------------------------------------------------|
| 31-0 | IntPnd[128:1] | 0     | Interrupt Pending Bits (for all message objects)       |
|      |               | 0     | This message object is not the source of an interrupt. |
|      |               | 1     | This message object is the source of an interrupt.     |

### 27.17.15 Message Valid X Register (DCAN MSGVAL X)

With the Message Valid X Register, the CPU can detect if one or more bits in the different Message Valid Registers are set. Each bit of this register represents a group of eight message objects. If at least one of the MsgVal bits of these message objects are set, the corresponding bit in the Message Valid X Register will be set.

**Figure 27-42. Message Valid X Register (DCAN MSGVAL X) [offset = C0h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

#### Example 3

Bit 0 of the Message Valid X Register represents byte 0 of the Message Valid 1 Register. If one or more bits in this byte are set, bit 0 of the Message Valid X Register will be set.

### 27.17.16 Message Valid Registers (DCAN MSGVAL12 to DCAN MSGVAL78)

These registers hold the MsgVal bits of the implemented message objects. By reading out these bits, the CPU can check which message objects are valid. The MsgVal bit of a specific message object can be set/reset by the CPU via the IF1/IF2 Interface Register sets, or by the Message Handler after a reception or a successful transmission.

**Figure 27-43. Message Valid 12 Register [offset = C4h]**

**Table 27-18. Message Valid Registers Field Descriptions**

| Bit  | Name          | Value | Description                                                                      |
|------|---------------|-------|----------------------------------------------------------------------------------|
| 31-0 | MsgVal[128:1] |       | Message Valid Bits (for all message objects)                                     |
|      |               | 0     | This message object is ignored by the Message Handler.                           |
|      |               | 1     | This message object is configured and will be considered by the Message Handler. |

### 27.17.17 Interrupt Multiplexer Registers (DCAN INTMUX12 to DCAN INTMUX78)

The IntMux flag determine for each message object, which of the two interrupt lines (DCAN0INT or DCAN1INT) will be asserted when the IntPnd of this message object is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN Control Register.

The IntPnd bit of a specific message object can be set or reset by the CPU via the IF1/IF2 Interface Register sets, or by Message Handler after reception or successful transmission of a frame. This will also affect the Int0ID resp Int1ID flags in the Interrupt Register.

|      |               | 0     | DCAN0INT line is active if corresponding IntPnd flag is one.                                                                                                                                                                                                  |
|      |               | 1     | DCAN1INT line is active if corresponding IntPnd flag is one.                                                                                                                                                                                                  |

### 27.17.18 IF1/IF2 Command Registers (DCAN IF1CMD, DCAN IF2CMD)

The IF1/IF2 Command Register configure and Initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred.

A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress.

After 4 to 14 VBUS clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage.

If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed.

**NOTE:** While Busy bit is one, IF1/IF2 Register sets are write protected.

For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAActive flag by r/w) is disabled during Debug/Suspend mode.

If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

**Figure 27-51. IF1 Command Registers (DCAN IF1CMD) [offset = 100h]**

|      |                | 1h-80h  | Valid message numbers if 128 message objects are implemented                                                                                                                                                                                                                                                                                                                                                                                        |
|      |                | 81h-FFh | Invalid message numbers if 128 message objects are implemented<br><b>Note:</b> When an invalid message number is written to the IF1/IF2 Command Register which is higher than the last implemented message object number, a modulo addressing will occur. For example, when accessing message object 33 in a DCAN module with 32 message objects only, the message object 1 will be accessed instead.                                               |

### 27.17.19 IF1/IF2 Mask Registers (DCAN IF1MSK, DCAN IF2MSK)

The bits of the IF1/IF2 Mask Registers mirror the mask bits of a message object. The function of the relevant message objects bits is described in [Section 27.5.1](#).

**NOTE:** While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write protected.

**Figure 27-53. IF1 Mask Register (DCAN IF1MSK) [offset = 104h]**

LEGEND: R/W = Read/Write; R = Read; WP = Protected Write (protected by Busy bit); -n = value after reset

**Figure 27-54. IF2 Mask Register (DCAN IF2MSK) [offset = 124h]**

LEGEND: R/W = Read/Write; R = Read; WP = Protected Write (protected by Busy bit); -n = value after reset

**Table 27-21. IF1/IF2 Mask Register Field Descriptions**

| Bit  | Field     | Value | Description                                                                                                                                                                                                                                                                                             |
|------|-----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | MXtd      |       | Mask Extended Identifier                                                                                                                                                                                                                                                                                |
|      |           | 0     | The extended identifier bit (IDE) has no effect on the acceptance filtering.                                                                                                                                                                                                                            |
|      |           | 1     | The extended identifier bit (IDE) is used for acceptance filtering.<br>When 11-bit ("standard") identifiers are used for a message object, the identifiers of received Data Frames are written into bits ID[28:18]. For acceptance filtering, only these bits with mask bits Msk[28:18] are considered. |
| 30   | MDir      |       | Mask Message Direction                                                                                                                                                                                                                                                                                  |
|      |           | 0     | The message direction bit (Dir) has no effect on the acceptance filtering.                                                                                                                                                                                                                              |
|      |           | 1     | The message direction bit (Dir) is used for acceptance filtering.                                                                                                                                                                                                                                       |
| 29   | Reserved  | 1     | This bit is always read as 1. Writes have no effect.                                                                                                                                                                                                                                                    |
| 28-0 | Msk[28:0] |       | Identifier Mask                                                                                                                                                                                                                                                                                         |
|      |           | 0     | The corresponding bit in the identifier of the message object is not used for acceptance filtering (don't care).                                                                                                                                                                                        |
|      |           | 1     | The corresponding bit in the identifier of the message object is used for acceptance filtering                                                                                                                                                                                                          |

### 27.17.20 IF1/IF2 Arbitration Registers (DCAN IF1ARB, DCAN IF2ARB)

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The function of the relevant message objects bits is described in [Section 27.5.1](#).

**NOTE:** While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write protected.

**Figure 27-55. IF1 Arbitration Register (DCAN IF1ARB) [offset = 108h]**

LEGEND: R/W = Read/Write; R = Read; WP = Protected Write (protected by Busy bit); -n = value after reset

**Figure 27-56. IF2 Arbitration Register (DCAN IF2ARB) [offset = 128h]**

The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).

Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.

If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

### 27.17.21 IF1/IF2 Message Control Registers (DCAN IF1MCTL, DCAN IF2MCTL)

The bits of the IF1/IF2 Message Control Registers mirror the message control bits of a message object. The function of the relevant message objects bits is described in [Section 27.5.1](#).

**NOTE:** While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write protected.

When the message handler stores a data frame, it will write the DLC to the value given by the received message. |

### 27.17.22 IF1/IF2 Data A and Data B Registers (DCAN IF1DATA/DATB, DCAN IF2DATA/DATB)

The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order.

In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first

### 27.17.23 IF3 Observation Register (DCAN IF3OBS)

The IF3 register set can automatically be updated with received message objects without the need to Initiate the transfer from Message RAM by CPU (Additional information can be found in [Section 27.5.1](#)).

The observation flags (Bits [4:0]) in the IF3 Observation register are used to determine, which data sections of the IF3 Interface Register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 Interface Register set with new data.

Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.

**NOTE:** If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses.

A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 Interface Register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register.

The status of the current read-cycle can be observed via status flags (Bits [12:8]).

If an interrupt line is available for IF3, an interrupt will be generated by IF3Upd flag. See the device data sheet to find out if this interrupt source is available

With this, the observation status bits and the IF3Upd bit could be used by the application to realize the notification about new IF3 content in polling or interrupt mode.

| 7   | EoB      | 0<br>1        | End of Block<br>The message object is part of a FIFO Buffer block and is not the last message object of the FIFO Buffer block<br>The message object is a single message object or the last message object in a FIFO Buffer block<br><b>Note:</b> This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one. |
| 6-4 | Reserved | 0             | These bits are always read as 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                            |
| 3-0 | DLC[3:0] | 0-8h<br>9h-Fh | Data Length Code<br>Data Frame has 0-8 data bytes.<br>Data Frame has 8 data bytes.<br><b>Note:</b> The Data Length Code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.                                                                  |

### 27.17.27 IF3 Data A and Data B Registers (DCAN IF3DATA/DATB)

The data bytes of CAN messages are stored in the IF3 registers in the following order.

In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

**Figure 27-67. IF3 Data A Register (DCAN IF3DATA) [offset = 150h]**

### 27.17.28 IF3 Update Enable Registers (DCAN IF3UPD12 to IF3UPD78)

The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UpdEn flag is set. This means that an active NewDat flag of this message object (for example, due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set.

**NOTE:** IF3 Update enable should not be set for transmit objects.

**Figure 27-69. IF3 Update Enable 12 Register [offset = 160h]**

|------|-----------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | IF3UpdEn[128:1] |       | IF3 Update Enabled (for all message objects)                                                                                                                             |
|      |                 | 0     | Automatic IF3 update is disabled for this message object.                                                                                                                |
|      |                 | 1     | Automatic IF3 update is enabled for this message object. A message object is scheduled to be copied to IF3 register set, if NewDat flag of the message object is active. |

### 27.17.29 CAN TX IO Control Register (DCAN TIOC)

The CAN\_TX pin of the DCAN module can be used as general purpose IO pin if CAN function is not needed.

**NOTE:** The values of the IO Control registers are only writable if Init bit of CAN Control Register is set.

The OD, Func, Dir and Out bits of the CAN TX IO Control register are forced to certain values when Init bit of CAN Control Register is reset (see bit descriptions).

**Figure 27-73. CAN TX IO Control Register (DCAN TIOC) [offset = 1E0h]**

### 27.17.30 CAN RX IO Control Register (DCAN RIOC)

The CAN\_RX pin of the DCAN module can be used as general purpose IO pin if CAN function is not needed.

**NOTE:** The values of the IO Control registers are writable only if Init bit of CAN Control Register is set.

The OD, Func and Dir bits of the CAN RX IO Control register are forced to certain values when Init bit of CAN Control Register is reset, see bit description.

**Figure 27-74. CAN RX IO Control Register (DCAN RIOC) [offset = 1E4h]**

## ***Multi-Buffered Serial Peripheral Interface Module (MibSPI) with Parallel Pin Option (MibSPIP)***

---

---

---

This chapter provides the specifications for a 16-bit configurable synchronous multi-buffered multi-pin serial peripheral interface (MibSPI). This chapter also provides the specifications for MibSPI with Parallel Pin Option (MibSPIP). The MibSPI is a programmable-length shift register used for high-speed communication between external peripherals or other microcontrollers.

Throughout this chapter, all references to SPI also apply to MibSPI/MibSPIP, unless otherwise noted.

---

**NOTE:** This chapter describes a superset implementation of the MibSPI/SPI modules that includes features and functionality that may not be available on some devices. Device-specific content that should be determined by referencing the datasheet includes DMA functionality, MibSPI RAM size, number of transfer groups, number of chip selects, parallel mode support, and availability of 5-pin operation (SPInENA).

---

## 28.1 Overview

The MibSPI/MibSPIP is a high-speed synchronous serial input/output port that allows a serial bit stream of programmed length (2 to 16 bits) to be shifted in and out of the device at a programmed bit-transfer rate. Typical applications for the SPI include interfacing to external peripherals, such as I/Os, memories, display drivers, and analog-to-digital converters.

The SPI has the following attributes:

- 16-bit shift register
- Receive buffer register
- 11-bit baud clock generator, supports max up to 20 MHz baud rate
- Serial clock (SPICLK) pin
- 1 SPISOMI/SPISIMO pin for data transfer, with programmable pin direction
- SPI enable ( $\overline{\text{SPIENA}}$ ) pin
- Up to 4 slave chip select ( $\overline{\text{SPISCS}}[3:0]$ ) pins.
- SPICLK can be internally-generated (and driven) or received from an external clock source
- Each word transferred can have a unique format
- SPI pins can be used as functional or digital Input/Output pins (GIOs)

---

**NOTE:** SIMO - Slave In Master Out Pin  
SOMI - Slave Out Master In Pin  
CS - SPI Chip Select Pin  
ENA - SPI Enable Pin.

---

### 28.1.1 Word Format Options

Each word transferred can have a unique format. Several format characteristics are programmable for each word transferred:

- SPICLK frequency
- Character length (2 to 16 bits)
- Phase (with and without delay)
- Polarity (high or low)
- Parity enabled/disabled
- Chip Select(CS) timers for setup and hold
- Shift direction (Most Significant Bit(MSB)- first or Least Significant Bit(LSB)- first)
- Multi-pin parallel modes

### 28.1.2 Multi-buffering (Mib) support

The MibSPI has a programmable buffer memory that enables programmed transmission to be completed without CPU intervention. The buffers are combined in different Transfer Groups (TGs) that can be triggered by external events (timers, Input/Output activity, etc.) or by the internal tick counter. The internal tick counter supports periodic trigger events. Each buffer of the MibSPI can be associated with different DMA channels in different TGs, allowing the user to move data between internal memory and an external slave with minimal CPU interaction.

### 28.1.2.1 Multi-buffer Mode

Multi-buffer Mode is an extension to the SPI. In multi-buffer mode, many extended features are configurable:

- Number of buffers for each peripheral (or data source/destination, up to 128 buffers supported) or group (up to 8 groupings)
- Triggers for each groups, trigger types, trigger sources for individual groups (14 external trigger sources and 1 internal trigger source supported)
- Memory fault detection via an internal parity circuit
- Number of DMA-controlled buffers and number of DMA request channels (up to 8 for each of transmit and receive)
- Number of DMA transfers for each buffer (up to 65536 words for up to 8 buffers)
- Uninterrupted DMA buffer transfer (NOBREAK buffer)

### 28.1.2.2 Compatibility Mode

Compatibility Mode of the MibSPI makes it behave exactly like a standard platform SPI module and ensures full compatibility with other SPIs. All features in compatibility mode of the MibSPI are directly applicable to a SPI. Multi-buffer Mode features are not available in Compatibility Mode.

---

**NOTE:** The SPIDAT0 register is not accessible in the multi-buffer mode of MibSPI. It is only accessible in compatibility mode.

---

### 28.1.3 Transmission Lock (Multi-Buffer Mode Master Only)

Some slave devices require transmission of a command followed by data. In this case the SPI transaction should not be interrupted by another group transfer. The LOCK bit within each buffer allows a consecutive transfer to happen without being interrupted by another higher-priority group transfer.

## 28.2 Operating Modes

The SPI can be configured via software to operate as either a master or a slave. The MASTER bit (SPIGCR1[0]) selects the configuration of the SPISIMO and SPISOMI pins. CLKMOD bit (SPIGCR1[1]) determines whether an internal or external clock source will be used.

The slave chip select ( $\overline{\text{SPISCS}}[3:0]$ ) pins, are used when communicating with multiple slave devices. When the a write occurs to SPIDAT1 in master mode, the  $\overline{\text{SPISCS}}$  pins are automatically driven to select the specified slave.

Handshaking mechanism, provided by the  $\overline{\text{SPIENA}}$  pin, enables a slave SPI to delay the generation of the clock signal supplied by the master if it is not prepared for the next exchange of data.

### 28.2.1 Pin Configurations

The SPI supports data connections as shown in [Table 28-1](#).

---

**NOTE:**

1. When the SPICCS[3:0] signals are disabled, the chip-select field in the transmit data is not used.
  2. When the SPIENA signal is disabled, the  $\overline{\text{SPIENA}}$  pin is ignored in master mode, and not driven as part of the SPI transaction in slave mode.
-

| Pin        | Master Mode                           |                                                                       | Slave Mode                                  |                                                                          |

- 1 This is a representative diagram, which shows three-pin mode hardware.
- 2 TXBUF, RXBUF, and SHIFT\_REGISTER are user-invisible registers.
- 3 SPIDAT0 and SPIDAT1 are user-visible, and are physically mapped to the contents of TXBUF.
- 4 SPISIMO, SPISOMI, SPICLK pin directions depend on the Master or Slave Mode.

**28.2.2.1 Data Sequencing when SPIDAT0 or SPIDAT1 is Written**

- If both the TX shift register and TXBUF are empty, then the data is directly copied to the TX shift register. For devices with DMA, if DMA is enabled, a transmit DMA request (TX\_DMA\_REQ) is generated to cause the next word to be fetched. If transmit interrupts are enabled, a transmitter-empty interrupt is generated.
- If the TX shift register is already full or is in the process of shifting and if TXBUF is empty then the data written to SPIDAT0 / SPIDAT1 is copied to TXBUF and TXFULL flag is set to 1 at the same time.
- When a shift operation is complete, data from the TXBUF (if it is full) is copied into TX shift register and the TXFULL flag is cleared to 0 to indicate that next data can be fetched. A transmit DMA request (if enabled) or a transmitter-empty interrupt (if enabled) is generated at the same time.

**28.2.2.2 Data Sequencing when All Bits Shifted into RXSHIFT Register**

- If both SPIBUF and RXBUF are empty, the received data in RX shift register is directly copied into SPIBUF and the receive DMA request (if enabled) is generated and the receive-interrupt (if enabled) is generated. The RXEMPTY flag in SPIBUF is cleared at the same time.
- If SPIBUF is already full at the end of receive completion, the RX shift register contents is copied to RXBUF. A receive DMA request is generated, if enabled. The receive complete interrupt line remains high.
- If SPIBUF is read by the CPU or DMA and if RXBUF is full, then the contents of RXBUF are copied to SPIBUF as soon as SPIBUF is read. RXEMPTY flag remains cleared, indicating that SPIBUF is still full.
- If both SPIBUF and RXBUF are full, then RXBUF will be overwritten and the RXOVR interrupt flag is set and an interrupt is generated, if enabled.

### 28.2.2.3 Three-Pin Mode

In master mode configuration (MASTER = 1 and CLKMOD = 1), the SPI provides the serial clock on the SPICLK pin. Data is transmitted on the SPISIMO pin and received on the SPISOMI pin (see [Figure 28-2](#)).

Data written to the shift register (SPIDAT0 / SPIDAT1) initiates data transmission on the SPISIMO pin, MSB first. Simultaneously, received data is shifted through the SPISOMI pin into the LSB of the SPIDAT0 register. When the selected number of bits have been transmitted, the received data in the shift register is transferred to the SPIBUF register for the CPU to read. Data is stored right-justified in SPIBUF.

See [Section 28.2.2.1](#) and [Section 28.2.2.2](#) for details about the data handling for transmit and receive operations.

In slave mode configuration (MASTER = 0 and CLKMOD = 0), data shifts out on the SPISOMI pin and in on the SPISIMO pin. The SPICLK pin is used as the input for the serial shift clock, which is supplied from the external network master. The transfer rate is defined by this clock.

Data written to the SPIDAT0 or SPIDAT1 register is transmitted to the network when the SPICLK signal is received from the network master. To receive data, the SPI waits for the network master to send the SPICLK signal and then shifts data on the SPISIMO pin into the RX shift register. If data is to be transmitted by the slave simultaneously, it must be written to the SPIDAT0 or SPIDAT1 register before the beginning of the SPICLK signal.

**Figure 28-2. SPI Three-Pin Operation**

### 28.2.3 Operation with $\overline{\text{SPISCS}}$

In master mode, each chip select signal is used to select a specific slave. In slave mode, chip select signal is used to enable/disable the transfer. Chip-select functionality is enabled by setting one of the  $\overline{\text{SPISCS}}$  [3:0] pins as chip selects. It is disabled by setting all  $\overline{\text{SPISCS}}$  [3:0] pins as GIOs in  $\text{SPIPC0}[3:0]$

#### Multiple Chip Selects

The  $\overline{\text{SPISCS}}$  [3:0] pins that are used must be configured as functional pins in the  $\text{SPIPC0}[3:0]$  register. The default pattern to be put on the  $\overline{\text{SPISCS}}$  [3:0] when all the slaves are deactivated is set in the  $\text{SPIDEF}$  register. This pattern allows different slaves with different chip-select polarity to be activated by the SPI.

The master-mode SPI is capable of driving either 0 or 1 as the active value for any  $\overline{\text{SPISCS}}[3:0]$  output pin. The drive state for  $\overline{\text{SPISCS}}[3:0]$  pins is controlled by the  $\text{CSNR}$  field of  $\text{SPIDAT1}$ . The pattern that is driven will select the slave to which the transmission is dedicated.

In slave mode, the SPI can only be selected by an active value of 0 on any of its selected  $\overline{\text{SPISCS}}$  input pin.

Figure 28-3. Operation with  $\overline{\text{SPISCS}}$

### 28.2.4 Operation with $\overline{\text{SPIENA}}$

The  $\overline{\text{SPIENA}}$  operates as a WAIT signal pin. For both the slave and the master, the  $\overline{\text{SPIENA}}$  pin must be configured to be functional (SPIPC0[8] = 1). In this mode, an active low signal from the slave on the  $\overline{\text{SPIENA}}$  pin allows the master SPI to drive the clock pulse stream. A high signal tells the master to hold the clock signal (and delay SPI activity).

If the  $\overline{\text{SPIENA}}$  pin is in high-z mode (ENABLE\_HIGHZ = 1), the slave will put  $\overline{\text{SPIENA}}$  into the high-impedance once it completes receiving a new character. If the  $\overline{\text{SPIENA}}$  pin is in push-pull mode (ENABLE\_HIGHZ = 0), the slave will drive  $\overline{\text{SPIENA}}$  to 1 once it completes receiving a new character. The slave will drive  $\overline{\text{SPIENA}}$  low again for the next word to transfer, after new data is written to the slave TX shift register.

In master mode (CLKMOD = 1), if the  $\overline{\text{SPIENA}}$  pin is configured as functional, then the pin will act as an input pin. If configured as a slave SPI and as functional, the  $\overline{\text{SPIENA}}$  pin acts as an output pin.

**NOTE:** During a transfer, if a slave-mode SPI detects a deassertion of its chip select before its internal character length counter overflows, then it places SPISOMI and  $\overline{\text{SPIENA}}$  (if ENABLE\_HIGHZ bit is set to 1) in high-z mode. Once this condition has occurred, if a SPICLK edge is detected while the chip select is deasserted, then the SPI stops that transfer and sets a DLENERR error flag and generates an interrupt (if enabled).

**Figure 28-4. Operation with  $\overline{\text{SPIENA}}$**

## 28.2.5 Five-Pin Operation (Hardware Handshaking)

Five-pin operation combines the functionality of three-pin mode, plus the enable pin and one or more chip select pins. The result is full hardware handshaking. To use this mode, both the  $\overline{\text{SPIENA}}$  pin and the required number of  $\overline{\text{SPISCS}}$  [3:0] pins must be configured as functional pins.

If the  $\overline{\text{SPIENA}}$  pin is in high-z mode ( $\text{ENABLE\_HIGHZ} = 1$ ), the slave SPI will put this signal into the high-impedance state by default. The slave will drive the signal  $\overline{\text{SPIENA}}$  low when new data is written to the slave shift register and the slave has been selected by the master ( $\overline{\text{SPISCS}}$  is low).

If the  $\overline{\text{SPIENA}}$  pin is in push-pull mode ( $\text{ENABLE\_HIGHZ} = 0$ ), the slave SPI drives this pin high by default when it is in functional mode. The slave SPI will drive the  $\overline{\text{SPIENA}}$  signal low when new data is written to the slave shift register ( $\text{SPIDAT0}/\text{SPIDAT1}$ ) and the slave is selected by the master ( $\overline{\text{SPISCS}}$  is low). If the slave is deselected by the master ( $\overline{\text{SPISCS}}$  goes high), the slave  $\overline{\text{SPIENA}}$  signal is driven high.

**NOTE:** Push-pull mode of the  $\overline{\text{SPIENA}}$  pin can be used only when there is a single slave in the system. When multiple SPI slave devices are connected to the common  $\overline{\text{SPIENA}}$  pin, all of the slaves should configure their  $\overline{\text{SPIENA}}$  pins in high-Z mode.

In master mode, if the  $\overline{\text{SPISCS}}$  pins are configured as functional pins, then the pins will be in output mode. A write to the master's  $\text{SPIDAT1}/\text{SPIDAT0}$  register will automatically drive the  $\overline{\text{SPISCS}}$  signals low. The master will drive the  $\overline{\text{SPISCS}}$  signals high again after completing the transfer of the bits of the data.

In slave mode ( $\text{CLKMOD} = 0$ ), the  $\overline{\text{SPISCS}}$  pins will act as SPI functional inputs.

Figure 28-5. SPI Five-Pin Option with  $\overline{\text{SPIENA}}$  and  $\overline{\text{SPISCS}}$

## 28.2.6 Data Formats

To support multiple different types of slaves in one SPI network, four independent data word formats are implemented that allow configuration of individual data word length, polarity, phase, and bit rate. Each word transmitted can select which data format to use via the bits DFSEL[1:0] in its control field from one of the four data word formats. Same data format can be supported on multiple chip selects.

Data formats 0, 1, 2, and 3 can be configured through SPIFMTx control registers.

Each SPI data format includes the standard SPI data format with enhanced features:

- Individually-configurable shift direction can be used to select MSB first or LSB first, whereas the position of the MSB depends on the configured data word length.
- Receive data is automatically right-aligned, independent of shift direction and data word length. Transmit data has to be written right-aligned into the SPI and the internal shift register will transmit according to the selected shift direction and data word length for correct transfer.
- To increase fault detection of data transmission and reception, an odd or even parity bit can be added at the end of a data word. The parity generator can be enabled or disabled individually for each data format. If a received parity bit does not match with the locally calculated parity bit, the parity error flag (PARITYERR) is set and an interrupt is asserted (if enabled).

Since the master-mode SPI can drive two consecutive accesses to the same slave, an 8-bit delay counter is available to satisfy the delay time for data to be refreshed in the accessed slave. The delay counter can be programmed as part of the data format.

CHARLEN[4:0] specifies the number of bits (2 to 16) in the data word. The CHARLEN[4:0] value directs the state control logic to count the number of bits received or transmitted to determine when a complete word is transferred.

Data word length **must** be programmed to the same length for both the **master** and the **slave**. However, when chip selects are used, there may be multiple targets with different lengths in the system.

---

**NOTE:** Data must be right-justified when it is written to the SPI for transmission irrespective of its character length or word length.

---

Figure 28-6 shows how a 12-bit word (0xEC9) needs to be written to the transmit buffer to be transmitted correctly.

**Figure 28-6. Format for Transmitting an 8-Bit Word**

| D15 | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| x   | x   | x   | x   | x   | x   | x  | x  | 1  | 1  | 0  | 0  | 1  | 0  | 0  | 1  |

---

**NOTE:** The received data is always stored right-justified regardless of the character length or direction of shifting and is padded with leading 0s when the character length is less than 16 bits.

---

Figure 28-7 shows how a 10-bit word (0x0A2) is stored in the buffer once it is received.

**Figure 28-7. Format for Receiving an 8-Bit Word**

| D15 | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| 0   | 0   | 0   | 0   | 0   | 0   | 0  | 0  | 1  | 0  | 1  | 0  | 0  | 0  | 1  | 0  |

## 28.2.7 Clocking Modes

**SPICLK** may operate in four different modes, depending on the choice of phase (delay/no delay) and the polarity (rising edge/falling edge) of the clock.

The data input and output edges depend on the values of both **POLARITY** and **PHASE** as shown in [Table 28-2](#).

**Table 28-2. Clocking Modes**

| POLARITY | PHASE | ACTION                                                                                                                                                     |
|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0        | 0     | Data is output on the rising edge of SPICLK. Input data is latched on the falling edge.                                                                    |
| 0        | 1     | Data is output one half-cycle before the first rising edge of SPICLK and on subsequent falling edges. Input data is latched on the rising edge of SPICLK.  |
| 1        | 0     | Data is output on the falling edge of SPICLK. Input data is latched on the rising edge.                                                                    |
| 1        | 1     | Data is output one half-cycle before the first falling edge of SPICLK and on subsequent rising edges. Input data is latched on the falling edge of SPICLK. |

[Figure 28-8](#) to [Figure 28-11](#) illustrate the four possible configurations of **SPICLK** corresponding to each mode. Having four signal options allows the SPI to interface with many different types of serial devices.

**Figure 28-8. Clock Mode with Polarity = 0 and Phase = 0**

Data is output on the rising edge of SPICLK.  
Input data is latched on the falling edge of SPICLK.

**Figure 28-9. Clock Mode with Polarity = 0 and Phase = 1**

Data is output one-half cycle before the first rising edge of SPICLK and on subsequent falling edges of SPICLK  
Input data is latched on the rising edge of SPICLK

**Figure 28-10. Clock Mode with Polarity = 1 and Phase = 0**

Data is output on the falling edge of SPICLK.  
Input data is latched on the rising edge of SPICLK.

**Figure 28-11. Clock Mode with Polarity = 1 and Phase = 1**

Data is output one-half cycle before the first falling edge of SPICLK and on the subsequent rising edges of SPICLK.  
Input data is latched on the falling edge of SPICLK.

## 28.2.8 Data Transfer Example

Figure 28-12 illustrates a SPI data transfer between two devices using a character length of five bits.

**Figure 28-12. Five Bits per Character (5-Pin Option)**

### 28.2.9 Decoded and Encoded Chip Select (Master Only)

In this device the SPI can connect to up to 4 individual slave devices using chip-selects by routing one wire to each slave. The 4 chip selects in the control field are directly connected to the 4 pins. The default value of each chip select (not active) can be configured via the register CSDEF. During a transmission, the value of the chip select control field (CSNR[7:0]) of the SPIDAT1 register (SPIDAT1[23:16]) is driven on the SPISCS [4:0] pins. When the transmission finishes the default chip-select value (defined by the CSDEF register) is put on the  $\overline{\text{SPISCS}}$  [4:0] pins.

The SPI can support more than 4 slaves by using encoded chip selects. To connect the SPI with encoded slaves devices, the CSNR field allows multiple active  $\overline{\text{SPISCS}}$  pins at the same time, which enables binary encoded chip selects from 0 to 16. To use encoded chip selects, all four chip select lines have to be connected to each slave device and each slave needs to have a unique chip-select address. The CSDEF register is used to provide the address at which slaves devices are all de-selected.

Users can combine decoded and encoded chip selects. For example,  $n$   $\overline{\text{SPISCS}}$  pins can be used for encoding a  $n$ -bit address and the remaining pins can be connected to decoded-mode slaves.

### 28.2.10 Variable Chip Select Setup and Hold Timing (Master Only)

In order to support slow slave devices a delay counter can be configured to delay data transmission after the chip select is activated. A second delay counter can be configured to delay the chip select deactivation after the last data bit is transferred. Both delay counters are clocked with peripheral clock(VCLK).

If a particular data format specifically does not require these additional set-up or hold times for the chip select pin(s), then they can be disabled in the corresponding SPIFMTx register.

### 28.2.11 Hold Chip-Select Active

Some slave devices require the chip select signal to be held continuously active during several consecutive data word transfers. Other slave devices require the chip select signal to be deactivated between consecutive data word transfers.

CSHOLD is programmable in both master and slave modes of the multi-buffer mode of SPI. However, the meaning of CSHOLD in master mode and slave mode are different.

---

**NOTE:** If the CSHOLD bit is set within the current data control field, the programmed hold time and the following programmed set-up time will not be applied between transactions.

---

#### 28.2.11.1 The CSHOLD Bit in Master Mode

Each word in a master-mode SPI can be individually initialized for one of the two modes via the CSHOLD bit in its control field.

If the CSHOLD bit is set in the control field of a word, the chip select signal will not be deactivated until the next control field is loaded with new chip select information. Since the chip-select is maintained active between two transfers, the chip-select hold delay (T2CDELAY) is not applied at the end of the current transaction, and the chip-select set-up time delay (C2TDELAY) is not applied as well at the beginning of the following transaction. However, the wait delay (WDELAY) will be still applied between the two transactions, if the WDEL bit is set within the control field.

Figure 28-13 shows the SPI pins when a master-mode SPI transfers a word that has its CSHOLD bit set. The chip-select pins will not be deasserted after the completion of this word. If the next word to transmit has the same chip-select number (CSNR) value, the chip select pins will be maintained until the completion of the second word, regardless of whether the CSHOLD bit is set or not.

**Figure 28-13. Typical Diagram when a Buffer in Master is in CSHOLD Mode (SPI-SPI)**

#### 28.2.11.2 The CSHOLD Bit in Slave Mode (Multibuffered Mode)

If the CSHOLD bit in a buffer is set to 1, then the MibSPI does not wait for the  $\overline{\text{SPISCS}}$  pins to be deasserted at the end of the shift operation to copy the received data to the receive RAM. With this feature, it is possible for a slave in multibuffer mode to do multiple data transfers without requiring the  $\overline{\text{SPISCS}}$  pins to be deasserted between two buffer transfers.

If the CSHOLD bit in a buffer is cleared to 0 in a slave MibSPI, even after the shift operation is done, the MibSPI waits until the  $\overline{\text{SPISCS}}$  pin (if functional) is deasserted to copy the received data to the RXRAM.

If the CSHOLD bit is maintained as 0 across all the buffers, then the slave in multibuffer mode requires its  $\overline{\text{SPISCS}}$  pins to be deasserted between any two buffer transfers; otherwise, the Slave SPI will be unable to respond to the next data transfer.

**NOTE:** In compatibility mode, the slave does not require the  $\overline{\text{SPISCS}}$  pin to be deasserted between two buffer transfers. The CSHOLD bit of the slave will be ignored in compatibility mode.

#### 28.2.12 Detection of Slave Desynchronization (Master Only)

When a slave supports generation of an enable signal (ENA), de-synchronization can be detected. With the enable signal a slave indicates to the master that it is ready to exchange data. A de-synchronization can occur if one or more clock edges are missed by the slave. In this case the slave may block the SOMI line until it detects clock edges corresponding to the next data word. This would corrupt the data word of the de-synchronized slave and the consecutive data word. A configurable 8 bit time-out counter, which is clocked with SPICLK, is implemented to detect this slave malfunction. After the transmission has finished (end of last bit transferred: either last data bit or parity bit) the counter is started. If the ENA signal generated by the slave does not become inactive before the counter overflows, the DESYNC flag is set and an interrupt is asserted (if enabled).

---

**NOTE: Inconsistency of Desync Flag in Compatibility Mode MibSPI**

Because of the nature of this error, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is due to the fact that receive completion flag/interrupt will be generated when the buffer transfer is completed. But desync will be detected after the buffer transfer is completed. So, if VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. This inconsistency in the desync flag is valid only in compatibility mode of MibSPI. In multi-buffer mode, the desync flag is always guaranteed to be for the current buffer.

---

**28.2.13 ENA Signal Time-Out (Master Only)**

The SPI in master mode waits for the hardware handshake signal (ENA) coming from the addressed slave before performing a data transfer. To avoid stalling the SPI by a non-responsive slave device a time-out value can be configured. If the time-out counter overflows before an active ENA signal is sampled the TIMEOUT flag in the status register SPIFLG is set and the TIMEOUT flag in the status field of the corresponding buffer is set.

---

**NOTE:** When the chip select signal becomes active, no breaks in transmission are allowed. The next arbitration is performed while waiting for the time-out to occur.

---

**28.2.14 Data-Length Error**

A SPI can generate an error flag by detecting any mismatch in length of received or transmitted data and the programmed character length under certain conditions.

**Data-Length Error in Master Mode:** During a data transfer, if the SPI detects a de-assertion of the  $\overline{\text{SPIENA}}$  pin (by the slave) while the character counter is not overflowed, then an error flag is set to indicate a data-length error. This can be caused by a slave receiving extra clocks (for example, due to noise on the SPICLK line).

---

**NOTE:** In a master mode SPI, the data length error will be generated only if the  $\overline{\text{SPIENA}}$  pin is enabled as a functional pin.

---

**Data-Length Error in Slave Mode:** During a transfer, if the SPI detects a de-assertion of the  $\overline{\text{SPISCS}}$  pin before its character length counter overflows, then an error flag is set to indicate a data-length error. This situation can arise if the slave SPI misses one or more SPICLK pulses from the master. This error in slave mode implies that both the transmitted and received data were not complete.

---

**NOTE:** In a slave-mode SPI, the data-length error flag will be generated only if at least one of the  $\overline{\text{SPISCS}}(x)$  pins are configured as functional, and are being used for selecting the slave.

---

**28.2.15 Parallel Mode (Multiple SIMO/SOMI Support, not available on all devices)**

In order to increase throughput, the parallel mode of the SPI enables the module to send data over more than one data line (Parallel 2, 4 or 8). When parallel mode is used, the data length must be set as 16 bits. Only module MIBSPIP5 supports Parallel Mode.

This feature increases throughput by 2 for 2 pins, by 4 for 4 pins, or by 8 for 8 pins.

Parallel mode supports the following features:

- Scalable data lines (1, 2, 4, 8) per direction. (SOMI and SIMO lines)
- All clock schemes are supported (clock phase and polarity)
- Parity is supported. The parity bit will be transmitted on bit0 of the SIMO/SOMI lines. The receive parity is expected on bit0 of the SOMI/SIMO pins.

Parallel mode can be programmed using the PMODEx[1:0] bits of SPIPMCTRL register. See [Section 28.9.24](#) for details about this register.

After reset the parallel mode selection bits are cleared (single SIMO/SOMI lines).

### 28.2.15.1 Parallel Mode Block Diagram

Figure 28-14 and Figure 28-15 show the parallel connections to the SPI shift register.

**Figure 28-14. Block Diagram Shift Register, MSB First**

**Figure 28-15. Block Diagram Shift Register, LSB First**

### 28.2.15.2 Parallel Mode Pin Mapping, MSB First

Table 28-3 and Table 28-4 describe the SOMI and SIMO pin mapping when the SPI is used in parallel mode (1, 2, 4, 8) pin mode, MSB first.

**NOTE:** MSB-first or LSB-first can be configured using the SHIFTDIRx bit of the SPIFMTx registers.

**Table 28-3. Pin Mapping for SIMO Pin with MSB First**

| Parallel Mode | Shift Register Bit | SIMO[7:0] |
|---------------|--------------------|-----------|
| 1             | 15                 | 0         |
| 2             | 15                 | 1         |
|               | 7                  | 0         |
| 4             | 15                 | 3         |
|               | 11                 | 2         |
|               | 7                  | 1         |
|               | 3                  | 0         |
| 8             | 15                 | 7         |
|               | 13                 | 6         |
|               | 11                 | 5         |
|               | 9                  | 4         |
|               | 7                  | 3         |
|               | 5                  | 2         |
|               | 3                  | 1         |
|               | 1                  | 0         |

**Table 28-4. Pin Mapping for SOMI Pin with MSB First**

| Parallel Mode | Shift Register Bit | SOMI[7:0] |
|---------------|--------------------|-----------|
| 1             | 0                  | 0         |
| 2             | 0                  | 0         |
|               | 8                  | 1         |
| 4             | 0                  | 0         |
|               | 4                  | 1         |
|               | 8                  | 2         |
|               | 12                 | 3         |
| 8             | 0                  | 0         |
|               | 2                  | 1         |
|               | 4                  | 2         |
|               | 6                  | 3         |
|               | 8                  | 4         |

|               | 12                 | 6         |
|               | 14                 | 7         |

### 28.2.15.3 Parallel Mode Pin Mapping, MSB-First, LSB-First

Table 28-5 and Table 28-6 describe the SIMO and SOMI pin mapping when SPI is used in parallel mode (1, 2, 4, 8) pin mode, LSB first.

**Table 28-5. Pin Mapping for SIMO Pin with LSB First**

| Parallel Mode | Shift Register Bit | SIMO[7:0] |
|---------------|--------------------|-----------|
| 1             | 0                  | 0         |
| 2             | 8                  | 1         |
|               | 0                  | 0         |
| 4             | 12                 | 3         |
|               | 8                  | 2         |
|               | 4                  | 1         |
|               | 0                  | 0         |
| 8             | 14                 | 7         |
|               | 12                 | 6         |
|               | 10                 | 5         |
|               | 8                  | 4         |
|               | 6                  | 3         |
|               | 4                  | 2         |
|               | 2                  | 1         |
|               | 0                  | 0         |

**Table 28-6. Pin Mapping for SOMI Pin with LSB First**

| Parallel Mode | Shift Register Bit | SOMI[7:0] |
|---------------|--------------------|-----------|
| 1             | 15                 | 0         |
| 2             | 7                  | 0         |
|               | 15                 | 1         |
| 4             | 3                  | 0         |
|               | 7                  | 1         |
|               | 11                 | 2         |
|               | 15                 | 3         |
| 8             | 1                  | 0         |
|               | 3                  | 1         |
|               | 5                  | 2         |
|               | 7                  | 3         |
|               | 9                  | 4         |
|               | 11                 | 5         |
|               | 13                 | 6         |
|               | 15                 | 7         |

#### 28.2.15.4 2-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 2-data line mode (master mode) the shift register bits 15 and 7 will be connected to the pins SIMO[1] and SIMO[0], and the shift register bits 8 and 0 will be connected to the pins SOMI[1] and SOMI[0] or vice versa in slave mode. After writing to the SPIDAT0/SPIDAT1 register, the bits 15 and 7 will be output on SIMO[1] and SIMO[0] on the rising edge of SPICLK. With the falling clock edge of the SPICLK, the received data on SOMI[1] and SOMI[0] will be latched to the shift register bits 8 and 0. The subsequent rising edge of SPICLK will shift the data in the shift register by 1 bit to the left. ( SIMO[1] will shift the data out from bit 15 to 8, SIMO[0] will shift the data out from bit 7 to 0). After eight SPICLK cycles, when the full data word is transferred, the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set. [Figure 28-16](#) shows the clock /data diagram of the 2-data line mode. [Figure 28-17](#) shows the timing of a two-pin parallel transfer.

**Figure 28-16. 2-data Line Mode (Phase 0, Polarity 0)**

**Figure 28-17. Two-Pin Parallel Mode Timing Diagram (Phase 0, Polarity 0)**

### 28.2.15.5 4-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 4-data line mode (master mode) the shift register bits 15, 11, 7, and 3 will be connected to the pins SIMO[3], SIMO[2], SIMO[1], and SIMO[0], and the shift register bits 12, 8, 4, and 0 will be connected to the pins SOMI[3], SOMI[2], SOMI[1], and SOMI[0] (or vice versa in slave mode). After writing to SPIDAT1/SPIDAT0, the bits 15, 11, 7, and 3 will be output on SIMO[3], SIMO[2], SIMO[1], and SIMO[0] on the rising edge of SPICLK. With the falling clock edge of the SPICLK, the received data on SOMI[3], SOMI[2], SOMI[1] and SOMI[0] will be latched to shift register bits 12, 8, 4, and 0. The subsequent rising edge of SPICLK will shift data in the shift register by 1 bit to the left ( SIMO[3] will shift the data out from bit 15 to 12, SIMO[2] will shift the data out from bit 11 to 8, SIMO[1] will shift the data out from bit 7 to 4, SIMO[0] will shift the data out from bit 3 to 0). After four SPICLK cycles, when the full data word is transferred, the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set.

Figure 28-18 shows the clock/data diagram of the four-data line mode. Figure 28-19, shows the timing diagram for four-data line mode.

**Figure 28-18. 4-Data Line Mode (Phase 0, Polarity 0)**

**Figure 28-19. 4 Pins Parallel Mode Timing Diagram (Phase 0, Polarity 0)**

### 28.2.15.6 8-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 8-data line mode (master mode) the shift register bits 15, 13, 11, 9, 7, 5 and 3 will be connected to the pins SIMO[7], SIMO[6], SIMO[5], SIMO[4], SIMO[3], SIMO[2], SIMO[1], and SIMO[0], and the shift-register bits 14, 12, 10, 8, 6, 4, and 0 will be connected to the pins SOMI[7], SOMI[6], SOMI[5], SOMI[4], SOMI[3], SOMI[2], SOMI[1], and SOMI[0] (or vice versa in slave mode).

After writing to SPIDAT0/SPIDAT1, the bits 15, 13, 11, 9, 7, 5, 3, and 1 will be output on SIMO[7], SIMO[6], SIMO[5], SIMO[4], SIMO[3], SIMO[2], SIMO[1], and SIMO[0], on the rising edge of SPICLK. On the falling clock edge of the SPICLK, the received data on SOMI[8], SOMI[7], SOMI[6], SOMI[5], SOMI[4], SOMI[3], SOMI[2], SOMI[1], and SOMI[0] will be latched to the shift register bits 14, 12, 10, 8, 6, 4, 2, and 0.

The subsequent rising edge of SPICLK will shift the data in the shift register by one bit to the left. After two SPICLK cycles, when the full data word is transferred the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set. [Figure 28-20](#) shows the clock/data diagram of the 8-data line mode. [Figure 28-21](#) shows the pin timings for 8-data line mode.

**Figure 28-20. Eight-data Line Mode (Phase 0, Polarity 0)**

**NOTE: Parity Support**

Using the parity support in parallel mode may seriously affect throughput. For an eight-line mode to transfer 16 bits of data, only two SPICLK pulses are enough. If parity is enabled, one extra SPICLK pulse will be used to transfer and receive the parity bit. Parity will be transmitted and received on the 0th line regardless of 1/2/4/8-line modes. During the parity bit transfer, other data bits are not valid.

**Figure 28-21. 8 Pins Parallel Mode Timing Diagram (Phase 0, Polarity 0)**

**NOTE:** Modulo Count Parallel Mode is not supported in this device.

### 28.2.16 Continuous Self-Test (Master/Slave)

During data transfer, the SPI compares its own internal transmit data with its transmit data on the bus. The sample point for the compare is at one-half SPI clock after transmit point. If the data on the bus does not match the expected value, the bit-error (BITERR) flag is set and an interrupt is asserted if enabled.

---

**NOTE:** The compare is made from the output pin using its input buffer.

---

### 28.2.17 Half Duplex Mode

SPI by protocol is Full Duplex in nature, which means simultaneous TX & RX operations happen on two separate data pins SIMO and SOMI. However, it is possible to use SPI/MibSPI to do the TX-only operation alone (ignoring the RX data), and RX-only operation (using dummy TX data and ignoring the TX pin). But this will require that both SOMI & SIMO lines are bonded out in a chip to be able to support both TX-only or RX-only features.

#### 28.2.17.1 Half Duplex Mode in Master

The Half Duplex Mode gives an additional flexibility to use the SIMO pin which is normally used TX pin in Master mode to work like an RX pin while the HDUPLEX\_ENAx bit is set to '1'. In Half Duplex Master mode, SIMO pin itself acts as an RX pin. Switching between Full Duplex and Half Duplex can be achieved using the SPIFMTx registers being selected using the DFSEL[1:0] bits of SPIDATx or TXRAM locations.

#### 28.2.17.2 Half Duplex Mode in Slave

In case of Slave mode, the SIMO pin which is normally an RX pin, will act as a TX pin while the HDUPLEX\_ENAx bit is set to '1'. In Half Duplex Slave mode, SIMO pin itself acts as a TX pin. Switching between Full Duplex and Half Duplex can be achieved using the SPIFMTx registers being selected using the DFSEL[1:0] bits of SPIDATx or TXRAM locations.

## 28.3 Test Features

### 28.3.1 Internal Loop-Back Test Mode (Master Only)

The internal loop-back self-test mode can be utilized to test the SPI transmit and receive paths, including the shift registers, the SPI buffer registers, and the parity generator. In this mode the transmit signal is internally fed back to the receiver, whereas the SIMO, SOMI, and CLK pin are disconnected; that is, the transmitted data is internally transferred to the corresponding receive buffer while external signals remain unchanged.

This mode allows the CPU to write into the transmit buffer, and check that the receive buffer contains the correct transmit data. If an error occurs the corresponding error is set within the status field.

---

**NOTE:** This mode cannot be changed during transmission.

---

### 28.3.2 Input/Output Loopback Test Mode

Input/Output Loopback Test mode supports the testing of all Input/Output pins without the aid of an external interface. Loopback can be configured as either analog-loopback (loopback through the pin-level input/output buffers) or digital loopback (internal to the SPI module). With Input/Output Loopback, all functional features of the SPI can be tested. Transmit data is fed back through the receive-data line(s). See Figure 28-22 for a diagram of the types of feedback available. The IOLPBKTSTCR register defines all of the available control fields.

In loopback mode, it is also possible to induce various error conditions. See Section 28.9.42 for details of the register field controlling these features.

In Input/Output loopback test modes, even when the module is in slave mode, the SPICLK is generated internally. This SPICLK is used for all loopback-mode SPI transactions. Slave-mode features can be tested without the help of another master SPI, using the internally-generated SPICLK. Chip selects are also generated by the slave itself while it is in Input/Output loopback mode.

In Input/Output loopback test modes, if the module is in master mode, the nENA signal is also generated by internal logic so that an external interface is not required.

---

**NOTE: Usage Guideline for Input/Output Loopback**

Input/Output Loopback mode should be used with caution because, in some configurations, even the receive pins will be driven with transmit data. During testing, it should be ensured that none of the SPI pins are driven by any other device connected to them. Otherwise, if analog loopback is selected in I/O Loopback mode, then testing may damage the device.

---

**Figure 28-22. I/O Paths during I/O Loopback Modes**

1 This diagram is intended to illustrate loopback paths and therefore may omit some normal-mode paths.

### 28.3.2.1 IO Loopback Mode Operation in Slave Mode

In multi-buffer slave mode, there are some additional requirements for using I/O loopback mode (IOLPBK). In multi-buffer slave mode, the chip-select pins are the triggers for various TGs. Enabling the IOLPBK mode by writing 0xA to the IOLPBTSTENA bits of the IOLPBKTSTCR register triggers TG0 by driving SPISCS[3:0] to 0x0. The actual number of chip selects can be programmed to have any or all of the SPISCS pins as functional. All other configurations should be completed before enabling the IOLPBK mode in multi-buffer slave mode since it triggers TG0.

After the first buffer transfer is completed, the CSNR[3:0] field of the current buffer is used to trigger the next buffer. So, if multiple TGs are desired to be tested, then the CSNR field of the final buffer in each TG should hold the number of the next TG to be triggered. As long as TG boundaries are well defined and are enabled, the completion of one TG will trigger the next TG.

To stop the transfer in multi-buffer slave mode in I/O Loopback configuration, either IOLPBK mode can be disabled by writing 0x5 to the IOLPBTSTENA bits or all of the TGs can be disabled.

## 28.4 General-Purpose I/O

All of the SPI pins may be programmed via the SPIPCx control registers to be either functional or general-purpose I/O pins.

If the SPI function is to be used, application software must ensure that at least the SPICLK pin and the SOMI and/or SIMO pins are configured as SPI functional pins, and not as GIO pins, or else the SPI state machine will be held in reset, preventing SPI transactions.

SPI pins support:

- internal pull-up resistors
- internal pull-down resistors
- open-drain or push-pull mode

## 28.5 Low-Power Mode

The SPI can be put into either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SPI. During global low-power mode, all clocks to the SPI are turned off, making the module completely inactive.

Local low-power mode is asserted by setting the POWERDOWN (SPIGCR1[8]) bit; setting this bit stops the clocks to the SPI internal logic and registers. Setting the POWERDOWN bit causes the SPI to enter local low-power mode and clearing the POWERDOWN bit causes SPI to exit from local low-power mode. All registers remain accessible during local power-down mode, since the clock to the SPI registers is temporarily re-enabled for each access. RAM buffers are also accessible during low power mode.

---

**NOTE:** Since entering a low-power mode has the effect of suspending all state-machine activities, care must be taken when entering such modes to ensure that a valid state is entered when low-power mode is active. Application software must ensure that a low power mode is not entered during a data transfer.

---

## 28.6 Interrupts

There are two levels of vectorized interrupts supported by the SPI. These interrupts can be caused under the following circumstances:

- Transmission error
- Receive overrun
- Receive complete (receive buffer full)
- Transmit buffer empty

These interrupts may be enabled or disabled via the SPIINT0 register.

During transmission, if one of the following errors occurs: BITERR, DESYNC, DLENERR, PARITYERR, or TIMEOUT, the corresponding bit in the SPIFLG register is set. If the corresponding enable bit is set, then an interrupt is generated. The level of all the above interrupts is set by the bit fields in the SPILVL register.

The error interrupts are enabled and prioritized independently from each other, but the interrupt generated will be the same if multiple errors are enabled on the same level. The SPIFLG register should be used to determine the actual cause of an error.

---

**NOTE:** Since there are two interrupt lines, one each for Level 0 and Level 1, it is possible for a programmer to separate out the interrupts for receive buffer full and transmit buffer empty. By programming one to Level 0 and the other to Level 1, it is possible to avoid a check on whether an interrupt occurred for transmit or for receive. A programmer can also choose to group all of the error interrupts into one interrupt line and both TX-empty and RX-full interrupts into another interrupt line using the LVL control register. In this way, it is possible to separate error-checking from normal data handling.

---

### 28.6.1 Interrupts in Multi-Buffer Mode

In multi-buffer mode, the SPI can generate interrupts on two levels.

In normal multi-buffer operation, the receive and transmit are not used and therefore the enable bits of SPIINT0 are not used.

The interrupts available in multi-buffer mode are:

- Transmission error interrupt
- Receive overrun interrupt
- TG suspended interrupt
- TG completed interrupt

When a TG has finished and the corresponding enable bit in the TGINTENA register is set, a transfer-finished interrupt is generated. The level of priority of the interrupt is determined by the corresponding bit in the TGINTLVL register.

When a TG is suspended by a buffer that has been set as suspend to wait until TXFULL flag or/and RXEMPTY flag are set, and if the corresponding bit in the TGINTENA register is set, an transfer-suspended interrupt is generated. The level of priority of the interrupt is determined by the corresponding bit in the TGINTLVL register.

[Figure 28-23](#) illustrates the TG interrupts.

Figure 28-23. TG Interrupt Structure

During transmission, if one of the following errors occurs, BITERR, DESYNC, PARITYERR, TIMEOUT, DLENERR, the corresponding flag in the SPIFLG register is set. If the enable bit is set, then an interrupt is generated. The level of the interrupts could be generated according to the bit field in SPILVL register.

The RXOVRN interrupt is generated when a buffer in the RXRAM is overwritten by a new received word. While writing newly received data to a RXRAM location, if the RXEMPTY bit of the corresponding location is 0, then the RXOVR bit will be set to 1 during the write operation, so that the buffer starts to indicate an overrun. This RXOVR flag is also reflected in SPIFLG register as RXOVRNINTFLG and the corresponding vector number is updated in TGINTVECT0/TGINTVECT1 register. If an overrun interrupt is enabled, then an interrupt will be generated indicating an overrun condition.

The error interrupts are enabled and prioritized independently from each other, but the vector generated by the SPI will be the same if multiple errors are enabled on the same level.

Figure 28-24. SPIFLG Interrupt Structure

Since the priority of an error interrupt is lower than a completion/suspend interrupt for a TG, the interrupts can be split into two levels. By programming all the error interrupts into Level 0 and TG-complete / TG-suspend interrupts into Level 1, it is possible to get a clear indication of the source of error interrupts. However, when a vector register shows an error interrupt, the actual buffer for which the error has occurred is not readily identifiable. Since each buffer in the multi-buffer RAM is stored along with its individual status flags, each buffer should be read until a buffer with any error flag set is found.

A separate interrupt line is provided to indicate the uncorrectable error condition in the MibSPI. This line is available (and valid) only in the multi-buffer mode of the MibSPI module and if the parity error detection feature for multi-buffer RAM is enabled.

## 28.8 Module Configuration

MibSPI/MibSPIP can be configured to function as Normal SPI and Multibuffered SPI. Upon power-up or a system-level reset, each bit in the module registers is set to a default state. The registers are writable only after the RESET bit is set to 1.

### 28.8.1 Compatibility(SPI) Mode Configuration

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as SPIENA is held low the entire time that the SPI is being configured, the order in which the registers are programmed is not important.

- Enable SPI by setting RESET bit.
- Configure the SIMO, SOMI, CLK and optional CSx, ENA pins for SPI functionality by setting the corresponding bit in SPIPC0 register.
- Configure the module to function as Master or Slave using CLKMOD and MASTER bits.
- Configure the required SPI data format using SPIFMTx register.
- If the module is selected to function as Master, the delay parameters can be configured using SPIDELAY register.
- Enable the Interrupts using SPIINT0 register if required.
- Select the CS to be used by setting CSNR bits in SPIDAT1 register.
- Configure CSHOLD and WDEL bits in SPIDAT1 register if required.
- Select the Data word format by setting DFSEL bits. Select the Number of the configured SPIFMTx register ( 0 to 3) to used for the communication.
- Set LOOPBACK bit to connect the transmitter to the receiver internally. (This feature is used to perform a self-test. Do not configure for normal communication to external devices).
- Set SPIENA to 1 after the SPI is configured.
- Perform Transmit and receive data, using SPIDAT1 and SPIBUF register.
- User must wait for TXFULL to reset or TXINT before writting next data to SPIDAT1 register.
- User must wait for RXEMPTY to reset or RXINT before reading the data from SPIBUF register.

### 28.8.2 MibSPI Mode Configuration

The following list details the configuration steps that software should perform prior to the transmission or reception of data in MIBSPI mode. As long as SPIENA is held low the entire time that the SPI is being configured, the order in which the registers are programmed is not important.

- Enable SPI by setting RESET bit.
- Set MSPIENA to 1 to get access to multi-buffer mode registers.
- Configure the SIMO, SOMI, CLK and optional CSx, ENA pins for SPI functionality by setting the corresponding bit in SPIPC0 register.
- Configure the module to function as Master or Slave using CLKMOD and MASTER bits.
- Configure the required SPI data format using SPIFMTx register.
- If the module is selected to function as Master, the delay parameters can be configured using SPIDELAY register.
- Check for BUFINITACTIVE bit to be active before configuring MIBSPI RAM. (From Device Power On it take Number of Buffers \* Peripheral clock period to initialize complete RAM.)
- Enable the Transfer Group interrupts using TGITENST register if required.
- Enable error interrupts using SPIINT0 register if required.
- Set SPIENA to 1 after the SPI is configured.
- The Trigger Source, Trigger Event, Transfer Group start address for the corresponding Transfer groups can be configured using the corresponding TGxCTRL register.
- Configure LPEND to specify the end address of the last TG.
- Similar to SPIDAT1 register 16 Bit Control fields in every TXRAM buffer in the TG has to be configured.
- Configure one of the eight BUFMODE available for each buffer.
- Fill the datas to be transmitted in TXDATA field in TXRAM buffers.
- Configure TGENA bit to enable the required Transfer groups. (In case of Trigger event always setting TGENA will trigger the transfer group).
- At the occurrence of the correct trigger event the Transfer group will be triggered and data gets transmitted and received one after the other with out any CPU intervention.
- User can poll Transfer-group interrupt flag or wait for a transfer-completed interrupt to read and write new data to the buffers.

## 28.9 Control Registers

This section describes the SPI control, data, and pin registers. The registers support 8-bit, 16-bit and 32-bit writes. The offset is relative to the associated base address of this module in a system. The base address for the control registers can be found in the device data sheet.

**NOTE:** TI highly recommends that write values corresponding to the reserved locations of registers be maintained as 0 consistently. This allows future enhancements to use these reserved bits as control bits without affecting the functionality of the module with any older versions of software.

When the SPIEN bit is 0 or cleared to 0, the following SPI registers get forced to their default states: <ul style="list-style-type: none"> <li>Both TX and RX shift registers</li> <li>The TXDATA fields of the SPI Transmit Data Register 0 (SPIDAT0) and the SPI Transmit Data Register 1 (SPIDAT1)</li> <li>All the fields of the SPI Flag Register (SPIFLG)</li> <li>Contents of SPIBUF and the internal RXBUF registers</li> </ul> The SPI is not activated for transfers.<br>Activates SPI                                                                                                                                                                                                                                                                                             |
| 23-17 | Reserved  | 0      | Reads returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 16    | LOOPBACK  | 0<br>1 | Internal loop-back test mode. The internal self-test option can be enabled by setting this bit. If the SPISIMO and SPISOMI pins are configured with SPI functionality, then the SPISIMO[7:0] pins are internally connected to the SPISOMI[7:0] pins (transmit data is looped back as receive data). GPIO mode for these pins is not supported in loopback mode. Externally, during loop-back operation, the SPICLK pin outputs an inactive value and SPISOMI[7:0] remains in the high-impedance state. If the SPI is initialized in slave mode or a data transfer is ongoing, errors may result.<br><br><b>Note: This loopback mode can only be used in master mode. Master mode must be selected before setting LOOPBACK. When this mode is selected, the CLKMOD bit should be set to 1, meaning that SPICLK is internally generated.</b><br>Internal loop-back test mode disabled.<br>Internal loop-back test mode enabled. |

**Table 28-10. SPI Interrupt Register (SPIINT0) Field Descriptions**

| Bit   | Field       | Value | Description                                                                                                                                                                                                                                                                                                    |
|-------|-------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-25 | Reserved    | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                         |
| 24    | ENABLEHIGHZ |       | $\overline{\text{SPIENA}}$ pin high-impedance enable. When active, the $\overline{\text{SPIENA}}$ pin (when it is configured as a WAIT functional output signal in a slave SPI) is forced to high-impedance when not driving a low signal. If inactive, then the pin will output both a high and a low signal. |
|       |             | 0     | $\overline{\text{SPIENA}}$ pin is pulled high when not active.                                                                                                                                                                                                                                                 |
|       |             | 1     | $\overline{\text{SPIENA}}$ pin remains high-impedance when not active.                                                                                                                                                                                                                                         |
| 23-17 | Reserved    | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                         |
| 16    | DMAREQEN    |       | DMA request enable. Enables the DMA request signal to be generated for both receive and transmit channels. Enable DMA REQ only after setting the SPIEN bit to 1.                                                                                                                                               |
|       |             | 0     | DMA is not used.                                                                                                                                                                                                                                                                                               |
|       |             | 1     | DMA requests will be generated.                                                                                                                                                                                                                                                                                |
|       |             |       | <b>Note:</b> A DMA request will be generated on the TX DMA REQ line each time a word is copied to the shift register either from TXBUF or directly from SPIDAT0/SPIDAT1 writes.                                                                                                                                |
|       |             |       | <b>Note:</b> A DMA request will be generated on the RX DMA REQ line each time a word is copied to the SPIBUF register either from RXBUF or directly from the shift register.                                                                                                                                   |
| 15-10 | Reserved    | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                         |

**Table 28-10. SPI Interrupt Register (SPIINT0) Field Descriptions (continued)**

| Bit | Field        | Value             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|--------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9   | TXINTENA     | <p>0</p> <p>1</p> | <p>Causes an interrupt to be generated every time data is written to the shift register, so that the next word can be written to TXBUF. Setting this bit will generate an interrupt if the TXINTFLG bit (SPI Flag Register (SPIFLG)[9]) is set to 1.</p> <p>No interrupt will be generated upon TXINTFLG being set to 1.</p> <p>An interrupt will be generated upon TXINTFLG being set to 1.</p> <p>The transmitter empty interrupt is valid in compatibility mode of SPI only. In multi-buffered mode, this interrupts will not be generated, even if it is enabled.</p> <p><b>Note: An interrupt request will be generated as soon as this bit is set to 1. By default it will be generated on the INT0 line. The SPILVL register can be programmed to change the interrupt line.</b></p>                                                                                                                                                                            |
| 8   | RXINTENA     | <p>0</p> <p>1</p> | <p>Causes an interrupt to be generated when the RXINTFLAG bit (SPI Flag Register (SPIFLG)[8]) is set by hardware.</p> <p>Interrupt will not be generated.</p> <p>Interrupt will be generated.</p> <p>The receiver full interrupt is valid in compatibility mode of SPI only. In multi-buffered mode, this interrupts will not be generated, even if it is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 7   | Reserved     | 0                 | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## 28.9.5 SPI Flag Register (SPIFLG)

Software must check all flag bits when reading this register.

| 24    | BUFINITACTIVE | 0<br>1 | Indicates the status of multi-buffer initialization process. Software can poll for this bit to determine if it can proceed with the register configuration of multi-buffer mode registers or buffer handling.<br><br><b>Note: If the SPIFLG register is read while the multi-buffer RAM is being initialized, the BUF INIT ACTIVE bit will be read as 1. If SPIFLG is read after the internal automatic buffer initialization is complete, this bit will be read as 0. This bit will show a value of 1 as long as the nRESET bit is 0, but does not really indicate that buffer initialization is underway. Buffer initialization starts only when the nRESET bit is set to 1.</b><br><br>0 Multi-buffer RAM initialization is complete.<br>1 Multi-buffer RAM is still being initialized. Do not attempt to write to either multi-buffer RAM or any multi-buffer mode registers.                                                                                                                                                                                                                                                                                      |
| 23-10 | Reserved      | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 9     | TXINTFLG      | 0<br>1 | Transmitter-empty interrupt flag. Serves as an interrupt flag indicating that the transmit buffer (TXBUF) is empty and a new word can be written to it. This flag is set when a word is copied to the shift register either directly from SPIDAT0/SPIDAT1 or from the TXBUF register. This bit is cleared by one of following methods:<br><ul style="list-style-type: none"> <li>Writing a new data to either SPIDAT0 or SPIDAT1</li> <li>Writing a 0 to SPIEN (SPIGCR1[24])</li> </ul> 0 Transmit buffer is now full. No interrupt pending for transmitter empty.<br>1 Transmit buffer is empty. An interrupt is pending to fill the transmitter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 8     | RXINTFLG      | 0<br>1 | Receiver-full interrupt flag. This flag is set when a word is received and copied into the buffer register (SPIBUF). If RXINTEN is enabled, an interrupt is also generated. This bit is cleared under the following methods:<br><ul style="list-style-type: none"> <li>Reading the SPIBUF register</li> <li>Reading TGINTVECT0 or TGINTVECT1 register when there is a receive buffer full interrupt</li> <li>Writing a 1 to this bit</li> <li>Writing a 0 to SPIEN (SPIGCR1[24])</li> <li>System reset</li> </ul> During emulation mode, however, a read to the emulation register (SPIEMU) does not clear this flag bit.<br>0 No new received data pending. Receive buffer is empty.<br>1 A newly received data is ready to be read. Receive buffer is full.<br><br><b>Note: Clearing RXINTFLG bit by writing a 1 before reading the SPIBUF sets the RXEMPTY bit of the SPIBUF register too. In this way, one can ignore a received word. However, if the internal RXBUF is already full, the data from RXBUF will be copied to SPIBUF and the RXEMPTY bit will be cleared again. The SPIBUF contents should be read first if this situation needs to be avoided.</b> |

**Table 28-12. SPI Flag Register (SPIFLG) Field Descriptions (continued)**

| Bit | Field        | Value             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 6   | RXOVRNINTFLG | <p>0</p> <p>1</p> | <p>Receiver overrun flag. The SPI hardware sets this bit when a receive operation completes before the previous character has been read from the receive buffer. The bit indicates that the last received character has been overwritten and therefore lost. The SPI will generate an interrupt request if this bit is set and the RXOVRN INTEN bit (SPIINT0.6) is set high. This bit is cleared under the following conditions in compatibility mode of MibSPI:</p> <ul style="list-style-type: none"> <li>Reading TGINTVECT0 or TGINTVECT1 register when there is a receive-buffer-overrun interrupt</li> <li>Writing a 1 to RXOVRNINTFLG in the SPI Flag Register (SPIFLG) itself</li> <li>Writing a 0 to SPIEN</li> <li>Reading the data field of the SPIBUF register</li> </ul> <p><b>Note: Reading the SPIBUF register does not clear this RXOVRNINTFLG bit. If an RXOVRN interrupt is detected, then the SPIBUF may need to be read twice to get to the overrun buffer. This is due to the fact that the overrun will always occur to the internal RXBUF. Each read to the SPIBUF will result in RXBUF contents (if it is full) getting copied to SPIBUF.</b></p> <p><b>Note: There is a special condition under which the RXOVRNINTFLG flag gets set. If both SPIBUF and RXBUF are already full and while another reception is underway, if any errors (TIMEOUT, BITERR, and DLEN_ERR) occur, then RXOVRN in RXBUF and RXOVRNINTFLG in SPIFLG registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a receive overrun.</b></p> <p>In multi-buffer mode of MibSPI, this bit is cleared under the following conditions:</p> <ul style="list-style-type: none"> <li>Reading the RXOVRN_BUF_ADDR register</li> <li>Writing a 1 to RXOVRNINTFLG in the SPI Flag Register (SPIFLG) itself</li> </ul> <p>In multi-buffer mode, if RXOVRNINTFLG is set, then the address of the buffer which experienced the overrun is available in RXOVRN_BUF_ADDR.</p> |
| 5   | Reserved     | 0                 | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 4   | BITERRFLG    | <p>0</p> <p>1</p> | <p>Mismatch of internal transmit data and transmitted data. This flag can be cleared by one of the following methods.</p> <ul style="list-style-type: none"> <li>Write a 1 to this bit.</li> <li>Set the SPIENA bit to 0.</li> </ul> <p>0<br/>No bit error occurred.</p> <p>1<br/>A bit error occurred. The SPI samples the signal of the transmit pin (master: SIMO, slave: SOMI) at the receive point (half clock cycle after transmit point). If the sampled value differs from the transmitted value a bit error is detected and the flag BITERRFLG is set. If BITERRRENA is set an interrupt is asserted. Possible reasons for a bit error can be an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 3   | DESYNCFLG    | <p>0</p> <p>1</p> | <p>Desynchronization of slave device. Desynchronization monitor is active in master mode only. This flag can be cleared by one of the following methods:</p> <ul style="list-style-type: none"> <li>Write a 1 to this bit.</li> <li>Set SPIENA bit to 0.</li> </ul> <p>0<br/>No slave desynchronization detected.</p> <p>1<br/>A slave device is desynchronized. The master monitors the ENAB signal coming from the slave device and sets the DESYNC flag after the last bit is transmitted plus <math>t_{ZEDelay}</math>. If DESYNCENA is set an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Table 28-12. SPI Flag Register (SPIFLG) Field Descriptions (continued)**

| Bit | Field        | Value                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----|--------------|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | PARITYERRFLG | <div>0</div> <div>1</div> | <p>Calculated parity differs from received parity bit. If the parity generator is enabled (can be selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word the parity generator calculates the reference parity and compares it to the received parity bit. In the event of a mismatch the PARITYERR flag is set and an interrupt is asserted if PARERRENA is set. This flag can be cleared by one of the following methods:</p> <ul style="list-style-type: none"> <li>• Write a 1 to this bit.</li> <li>• Set SPIENA bit to 0.</li> </ul> <p>No parity error detected.</p> <p>A parity error occurred.</p>                                                                                                                     |
| 1   | TIMEOUTFLG   | <div>0</div> <div>1</div> | <p>Time-out caused by nonactivation of ENA signal. This flag can be cleared by one of the following methods:</p> <ul style="list-style-type: none"> <li>• Write a 1 to this bit.</li> <li>• Set SPIENA bit to 0.</li> </ul> <p>No ENA-signal time-out occurred.</p> <p>An ENA signal time-out occurred. The SPI generates a time-out because the slave hasn't responded in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition the TIMEOUT flag in the status field of the corresponding buffer is set. The transmit request of the concerned buffer is cleared, that is, the SPI does not re-start a data transfer from this buffer.</p> |
| 0   | DLENERRFLG   | <div>0</div> <div>1</div> | <p>Data-length error flag. This flag can be cleared by one of the following methods:</p> <ul style="list-style-type: none"> <li>• Write a 1 to this bit.</li> <li>• Set SPIENA bit to 0.</li> </ul> <p><b>Note: Whenever any transmission errors (TIMEOUT, BITERR, DLEN_ERR, PARITY_ERR, DESYNC) are detected and the error flags are cleared by writing to the error bit in the SPIFLG register, the corresponding error flag in SPIBUF does not get cleared. Software needs to read the SPIBUF until it becomes empty before proceeding. This ensures that all of the old status bits in SPIBUF are cleared before starting the next transfer.</b></p> <p>No data length error has occurred.</p> <p>A data length error has occurred.</p>                                                                    |

## 28.9.6 SPI Pin Control Register 0 (SPIPC0)

**NOTE:** Register bits vary by device

Register bits 31:24 and 23:16 of SPIPC0 to SPIPC9 reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

**Figure 28-31. SPI Pin Control Register 0 (SPIPC0) [offset = 14h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-13. SPI Pin Control (SPIPC0) Field Descriptions**

| Bit   | Field    | Value                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| 7-0 | SCSFUN | 0<br>1 | $\overline{\text{SPISCSx}}$ function. Determines whether each $\overline{\text{SPISCSx}}$ pin is to be used as a general-purpose I/O pin or as a SPI functional pin. If the slave $\overline{\text{SPISCSx}}$ pins are in functional mode and receive an inactive high signal, the slave SPI will place its output in high-z and disable shifting.<br>The $\overline{\text{SPISCSx}}$ pin is a GIO pin.<br>The $\overline{\text{SPISCSx}}$ pin is a SPI functional pin. |

### 28.9.7 SPI Pin Control Register 1 (SPIPC1)

**NOTE:** Register bits vary by device

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

**Figure 28-32. SPI Pin Control Register 1 (SPIPC1) [offset = 18h]**

| 10    | SIMODIR0 |       | SPISIMO0 direction. This bit controls the direction of the SPISIMO0 pin when it is used as a general-purpose I/O pin. If the SPISIMO0 pin is used as a SPI functional pin, the I/O direction is determined by the MASTER bit in the SPIGCR1 register.                                                                                                                                                               |
|       |          | 0     | The SPISIMO0 pin is a GPIO pin.                                                                                                                                                                                                                                                                                                                                                                                     |
|       |          | 1     | The SPISIMO0 pin is a SPI functional pin.                                                                                                                                                                                                                                                                                                                                                                           |
| 9     | CLKDIR   |       | SPICLK direction. This bit controls the direction of the SPICLK pin when it is used as a general-purpose I/O pin. In functional mode, the I/O direction is determined by the CLKMOD bit.                                                                                                                                                                                                                            |
|       |          | 0     | The SPICLK pin is an input.                                                                                                                                                                                                                                                                                                                                                                                         |
|       |          | 1     | The SPICLK pin is an output.                                                                                                                                                                                                                                                                                                                                                                                        |
| 8     | ENADIR   |       | $\overline{\text{SPIEN}}\overline{\text{A}}$ direction. This bit controls the direction of the $\overline{\text{SPIEN}}\overline{\text{A}}$ pin when it is used as a general-purpose I/O. If the $\overline{\text{SPIEN}}\overline{\text{A}}$ pin is used as a functional pin, then the I/O direction is determined by the CLKMOD bit (SPIGCR1[1]).                                                                 |
|       |          | 0     | The $\overline{\text{SPIEN}}\overline{\text{A}}$ pin is an input.                                                                                                                                                                                                                                                                                                                                                   |
|       |          | 1     | The $\overline{\text{SPIEN}}\overline{\text{A}}$ pin is an output.                                                                                                                                                                                                                                                                                                                                                  |
| 7-0   | SCSDIR   |       | $\overline{\text{SPISCS}}\overline{\text{x}}$ direction. These bits control the direction of each $\overline{\text{SPISCS}}\overline{\text{x}}$ pin when it is used as a general-purpose I/O pin. Each pin could be configured independently from the others. If the $\overline{\text{SPISCS}}\overline{\text{x}}$ is used as a SPI functional pin; the I/O direction is determined by the CLKMOD bit (SPIGCR1[1]). |
|       |          | 0     | The $\overline{\text{SPISCS}}\overline{\text{x}}$ pin is an input.                                                                                                                                                                                                                                                                                                                                                  |
|       |          | 1     | The $\overline{\text{SPISCS}}\overline{\text{x}}$ pin is an output.                                                                                                                                                                                                                                                                                                                                                 |

## 28.9.8 SPI Pin Control Register 2 (SPIPC2)

**NOTE: Register bits vary by device**

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

## 28.9.11 SPI Pin Control Register 5 (SPIPC5)

**NOTE:** Register bits vary by device

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

### 28.9.13 SPI Pin Control Register 7 (SPIPC7)

**NOTE: Register bits vary by device**

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

**NOTE: Default Register Value**

The default values of these register bits vary by device. See your device datasheet for information about default pin states, which correspond to the register reset values (see the pin-list table).

**Figure 28-38. SPI Pin Control Register 7 (SPIPC7) [offset = 30h]**

| 15-0  | TXDATA   | 0-FFFFh | <p><b>SPI transmit data.</b> When written, these bits will be copied to the shift register if it is empty. If the shift register is not empty, TXBUF holds the written data. SPIEN (SPICGR1[24]) must be set to 1 before this register can be written to. Writing a 0 to the SPIEN register forces the lower 16 bits of the SPIDAT0 to 0x00.</p> <p><b>Note: When this register is read, the contents TXBUF, which holds the latest written data, will be returned.</b></p> <p><b>Note: Regardless of character length, the transmit word should be right-justified before writing to the SPIDAT1 register.</b></p> <p><b>Note: The default data format control register for SPIDAT0 is SPIFMT0. However, it is possible to reprogram the DFSEL[1:0] fields of SPIDAT1 before using SPIDAT0, to select a different SPIFMTx register.</b></p> |

| 28    | CSHOLD   | 0<br>1              | Chip select hold mode. The CSHOLD bit is supported in master mode only in compatibility-mode of SPI, (it is ignored in slave mode). CSHOLD defines the behavior of the chip select line at the end of a data transfer.<br><br>0 The chip select signal is deactivated at the end of a transfer after the T2CDELAY time has passed. If two consecutive transfers are dedicated to the same chip select this chip select signal will be deactivated for at least 2VCLK cycles before it is activated again.<br><br>1 The chip select signal is held active at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1. If the new chip select number equals the previous one, the active chip select signal is extended until the end of transfer with CSHOLD cleared, or until the chip-select number changes. |

**Table 28-24. SPI Receive Buffer Register (SPIBUF) Field Descriptions**

| Bit | Field   | Value             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----|---------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31  | RXEMPTY | <p>0</p> <p>1</p> | <p><b>Receive data buffer empty.</b>When the host reads the SPIBUF field or the entire SPIBUF register, it automatically sets the RXEMPTY flag. When a data transfer is completed, the received data is copied into SPIBUF, and the RXEMPTY flag is cleared.</p> <p>New data has been received and copied into the SPIBUF field.</p> <p>No data has been received since the last read of SPIBUF.</p> <p>This flag gets set to 1 under the following conditions:</p> <ul style="list-style-type: none"> <li>Reading the RXDATA portion of the SPIBUF register.</li> <li>Writing a 1 to clear the RXINTFLG bit in the SPI Flag Register (SPIFLG).</li> </ul> <p>Write-clearing the RXINTFLG bit before reading the SPIBUF indicates the received data is being ignored. Conversely, RXINTFLG can be cleared by reading the RXDATA portion of SPIBUF (or the entire register).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 30  | RXOVR   | <p>0</p> <p>1</p> | <p>Receive data buffer overrun. When a data transfer is completed and the received data is copied into RXBUF while it is already full, RXOVR is set. Overruns always occur to RXBUF, not to SPIBUF; the contents of SPIBUF are overwritten only after it is read by the Peripheral (VBUSP) master (CPU, DMA, or other host processor).</p> <p>If enabled, the RXOVRN interrupt is generated when RXBUF is overwritten, and reading either SPI Flag Register (SPIFLG) or SPIVCTx shows the RXOVRN condition. Two read operations from the SPIBUF register are required to reach the overwritten buffer word (one to read SPIBUF, which then transfers RXDATA into SPIBUF for the second read).</p> <p>This flag is cleared to 0 when the RXDATA is read.</p> <p><b>Note: A special condition under which RXOVR flag gets set. If both SPIBUF and RXBUF are already full and while another buffer receive is underway, if any errors such as TIMEOUT, BITERR and DLEN_ERR occur, then RXOVR in RXBUF and SPI Flag Register (SPIFLG) registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receive overrun.</b></p> <p>0</p> <p>No receive data overrun condition occurred since last read of the data field.</p> <p>1</p> <p>A receive data overrun condition occurred since last read of the data field.</p> |
| 29  | TXFULL  | <p>0</p> <p>1</p> | <p><b>Transmit data buffer full.</b>This flag is a read-only flag. Writing into the SPIDAT0 or SPIDAT1 field while the TX shift register is full will automatically set the TXFULL flag. Once the word is copied to the shift register, the TXFULL flag will be cleared. Writing to SPIDAT0 or SPIDAT1 when both TXBUF and the TX shift register are empty does not set the TXFULL flag.</p> <p>0</p> <p>The transmit buffer is empty; SPIDAT0/SPIDAT1 is ready to accept a new data.</p> <p>1</p> <p>The transmit buffer is full; SPIDAT0/SPIDAT1 is not ready to accept new data.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 28-24. SPI Receive Buffer Register (SPIBUF) Field Descriptions (continued)**

| Bit   | Field     | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|-----------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 28    | BITERR    | 0       | <b>Bit error.</b> There was a mismatch of internal transmit data and transmitted data.<br><br>No bit error occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|       |           | 1       | <b>Note: This flag is cleared to 0 when the RXDATA portion of the SPIBUF register is read.</b><br><br>A bit error occurred. The SPI samples the signal of the transmit pins (master: SIMOx, slave: SOMIx) at the receive point (one-half clock cycle after the transmit point). If the sampled value differs from the transmitted value, a bit error is detected and the BITERR flag is set. Possible reasons for a bit error include noise, an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 27    | DESYNC    | 0       | <b>Desynchronization of slave device.</b> This bit is valid in master mode only.<br><br>The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus $t_{2EDELAY}$ . If DESYNCENA is set, an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.<br><br><b>Note: In the Compatibility Mode MibSPI, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is because the receive completion flag/interrupt is generated when the buffer transfer is completed. But desynchronization is detected after the buffer transfer is completed. So, if the VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. In multi-buffer mode, the desync flag is always guaranteed to be for the current buffer.</b> |
|       |           | 1       | No slave desynchronization detected.<br><br><b>Note: This flag is cleared to 0 when the RXDATA portion of the SPIBUF register is read.</b><br><br>A slave device is desynchronized.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 26    | PARITYERR | 0       | <b>Parity error.</b> The calculated parity differs from the received parity bit.<br><br>If the parity generator is enabled (selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word, the parity generator calculates the reference parity and compares it to the received parity bit. If a mismatch is detected, the PARITYERR flag is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|       |           | 1       | <b>Note: This flag is cleared to 0 when the RXDATA portion of the SPIBUF register is read.</b><br><br>No parity error detected.<br><br>A parity error occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 25    | TIMEOUT   | 0       | Time-out because of non-activation of ENA pin.<br><br>The SPI generates a time-out when the slave does not respond in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected, the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition, the TIMEOUT flag in the status field of the corresponding buffer and in the SPI Flag Register (SPIFLG) is set.<br><br><b>This bit is valid only in master mode.</b><br><br>This flag is cleared to 0 when RXDATA portion of the SPIBUF register is read.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|       |           | 1       | No ENA pin time-out occurred.<br><br>An ENA signal time-out occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 24    | DLENERR   | 0       | <b>Data length error flag.</b><br><br><b>Note: This flag is cleared to 0 when the RXDATA portion of the SPIBUF register is read.</b><br><br>No data-length error has occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 28-26. SPI Delay Register (SPIDELAY) Field Descriptions**

| Bit   | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------|----------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | C2TDELAY | 0-1FFh | <p><b>Chip-select-active to transmit-start delay.</b> See <a href="#">Figure 28-45</a> for an example. C2TDELAY is used only in master mode. It defines a setup time (for the slave device) that delays the data transmission from the chip select active edge by a multiple of VCLK cycles.</p> <p>The setup time value is calculated as follows.</p> $t_{C2TDELAY} = (C2TDELAY + 2) \times VCLK \text{ Period}$ <p>Note: If C2TDELAY = 0, then <math>t_{C2TDELAY} = 0</math>.</p> <p>Example: VCLK = 25 MHz -&gt; VCLK Period = 40ns; C2TDELAY = 07h;<br/> <math>&gt; t_{C2TDELAY} = 360 \text{ ns}</math></p> <p>When the chip select signal becomes active, the slave has to prepare data transfer within 360 ns.</p> <p><b>Note: If phase = 1, the delay between SPICS falling edge to the first edge of SPICLK will have an additional 0.5 SPICLK period delay. This delay is as per the SPI protocol.</b></p> |

**Table 28-26. SPI Delay Register (SPIDELAY) Field Descriptions (continued)**

| Bit   | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|----------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 23-16 | T2CDELAY | 0-1FFh | <p><b>Transmit-end-to-chip-select-inactive-delay.</b> See <a href="#">Figure 28-46</a> for an example. T2CDELAY is used only in master mode. It defines a hold time for the slave device that delays the chip select deactivation by a multiple of VCLK cycles after the last bit is transferred. The hold time value is calculated as follows:</p> $t_{T2CDELAY} = (T2CDELAY + 1) \times VCLK \text{ Period}$ <p><b>Note: If T2CDELAY = 0, then <math>t_{T2CDELAY} = 0</math></b></p> <p>Example: VCLK = 25 MHz -&gt; VCLK Period = 40ns; T2CDELAY = 03h;<br/> <math>&gt; t_{T2CDELAY} = 160 \text{ ns};</math></p> <p>After the last data bit (or parity bit) is being transferred the chip select signal is held active for 160 ns.</p> <p><b>Note: If phase = 0, then between the last edge of SPICLK and rise-edge of SPICS there will be an additional delay of 0.5 SPICLK period. This is as per the SPI protocol.</b></p> <p><b>Note: C2TDELAY and T2CDELAY counters do not count when SPIENA stops transmission.</b></p> <p>Both C2TDELAY and T2CDELAY counters do not have any dependency on the <math>\overline{\text{SPIENA}}</math> pin value. Even if the <math>\overline{\text{SPIENA}}</math> pin is asserted by the slave, the master will continue to delay the start of SPICLK until the C2TDELAY counter overflows.</p> <p>Similarly, even if the <math>\overline{\text{SPIENA}}</math> pin is deasserted by the slave, the master will continue to hold the SPISCS pins active until the T2CDELAY counter overflows. In this way, it is guaranteed that the setup and hold times of the <math>\overline{\text{SPISCS}}</math> pins are determined by the delay timers alone. To achieve better throughput, it should be ensured that these two timers are kept at the minimum possible values.</p> |
| 15-8  | T2EDELAY | 0-1FFh | <p><b>Transmit-data-finished to ENA-pin-inactive time-out.</b> T2EDELAY is used in master mode only. It defines a time-out value as a multiple of SPI clock before SPIENA signal has to become inactive and after SPISCS becomes inactive. SPICLK depends on which data format is selected. If the slave device is missing one or more clock edges, it becomes de-synchronized. In this case, although the master has finished the data transfer, the slave is still waiting for the missed clock pulses and the ENA signal isn't disabled.</p> <p>The T2EDELAY defines a time-out value that triggers the DESYNC flag, if the SPIENA signal isn't deactivated in time. The DESYNC flag is set to indicate that the slave device did not de-assert its <math>\overline{\text{SPIENA}}</math> pin in time to acknowledge that it received all bits of the sent word. See <a href="#">Figure 28-47</a> for an example of this condition.</p> <p><b>Note: DESYNC is also set if the SPI detects a de-assertion of <math>\overline{\text{SPIENA}}</math> before the end of the transmission. The time-out value is calculated as follows:</b></p> $t_{T2EDELAY} = T2EDELAY / \text{SPIClock}$ <p>Example: SPIClock = 8 Mbit/s; T2EDELAY = 10h;<br/> <math>&gt; t_{T2EDELAY} = 2 \mu\text{s};</math></p> <p>The slave device has to disable the ENA signal within 2 <math>\mu\text{s}</math>, otherwise DESYNC is set and an interrupt is asserted (if enabled).</p>                                                                                                                                                                                                                                                                                                                                                         |
| 7-0   | C2EDELAY | 0-1FFh | <p><b>Chip-select-active to ENA-signal-active time-out.</b> C2EDELAY is used only in master mode and it applies only if the addressed slave generates an ENA signal as a hardware handshake response. C2EDELAY defines the maximum time between when the SPI activates the chip-select signal and the addressed slave has to respond by activating the ENA signal. C2EDELAY defines a time-out value as a multiple of SPI clocks. The SPI clock depends on whether data format 0 or data format 1 is selected. See <a href="#">Figure 28-48</a> for an example of this condition.</p> <p><b>Note: If the slave device does not respond with the ENA signal before the time-out value is reached, the TIMEOUT flag in the SPIFLG register is set and a interrupt is asserted (if enabled).</b></p> <p>If a time-out occurs, the SPI clears the transmit request of the timed-out buffer, sets the TIMEOUT flag for the current buffer, and continues with the transfer of the next buffer in the sequence that is enabled.</p> <p>The timeout value is calculated as follows: <math>t_{C2EDELAY} = C2EDELAY / \text{SPIClock}</math></p> <p>Example: SPIClock = 8 Mbit/s; C2EDELAY = 30 h;<br/> <math>&gt; t_{C2EDELAY} = 6 \text{ ms};</math></p> <p>The slave device has to activate the ENA signal within 6 ms after the SPI has activated the chip select signal (<math>\overline{\text{SPISCS}}</math>), otherwise the TIMEOUT flag is set and an interrupt is asserted (if enabled).</p>                                                                                                                                                                                                                                                                                                                           |

| 31-24 | WDELAY    | 0-FFh  | Delay in between transmissions for data format x (x= 0,1,2,3). Idle time that will be applied at the end of the current transmission if the bit WDEL is set in the current buffer. The delay to be applied is equal to:<br>$WDELAY * P_{VCLK} + 2 * P_{VCLK}$ $P_{VCLK} \rightarrow \text{Period of VCLK.}$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 23    | PARPOL    | 0<br>1 | Parity polarity: even or odd. PARPOLx can be modified in privilege mode only. It can be used for data format x (x= 0,1,2,3).<br>An even parity flag is added at the end of the transmit data stream.<br>An odd parity flag is added at the end of the transmit data stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 22    | PARITYENA | 0<br>1 | Parity enable for data format x.<br>No parity generation/ verification is performed for this data format.<br>A parity bit is transmitted at the end of each transmitted word. At the end of a transfer the parity generator compares the received parity bit with the locally-calculated parity flag. If the parity bits do not match the RXERR flag is set in the corresponding control field. The parity type (even or odd) can be selected via the PARPOL bit.<br><b>Note: If an uncorrectable error flag is set in a slave-mode SPI, then the wrong parity bit will be transmitted to indicate to the master that there has been some issue with the data parity. The SOMI pins will be forced to transmit all 0s, and the parity bit will be transmitted as 1 if even parity is selected and as 0 if odd parity is selected (using the PARPOLx bit of this register). This behavior occurs regardless of an uncorrectable parity error on either TXRAM or RXRAM.</b> |
| 21    | WAITENA   | 0<br>1 | The master waits for the ENA signal from slave for data format x. WAITENA is valid in master mode only. WAITENA enables a flexible SPI network where slaves with ENA signal and slaves without ENA signal can be mixed. WAITENA defines, for each transferred word, whether the addressed slave generates the ENA signal or not.<br>The SPI does not wait for the ENA signal from the slave and directly starts the transfer.<br>Before the SPI starts the data transfer it waits for the ENA signal to become low. If the ENA signal is not pulled down by the addressed slave before the internal time-out counter (C2EDELAY) overflows, then the master aborts the transfer and sets the TIMEOUT error flag.                                                                                                                                                                                                                                                           |
| 20    | SHIFTDIR  | 0<br>1 | <b>Shift direction for data format x.</b> With bit SHIFTDIRx, the shift direction for data format x (x=0,1,2,3) can be selected.<br>MSB is shifted out first.<br>LSB is shifted out first.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table 28-28. SPI Data Format Registers (SPIFMT) Field Descriptions (continued)**

| Bit  | Field         | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|---------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19   | HDUPLEX_ENAx  | 0<br>1 | <p><b>Half Duplex transfer mode enable for Data Format x.</b> This bit controls the I/O function of SOMI/SIMO lines for a specific requirement where in the case of Master mode, TX pin - SIMO will act as an RX pin, and in the case of Slave mode, RX pin - SIMO will act as a TX pin..</p> <p>Normal Full Duplex transfer.</p> <p>If MASTER = '1', SIMO pin will act as an RX pin (No TX possible) If MASTER = '0', SIMO pin will act as a TX pin (No RX possible).</p> <p>For all normal operations, HDUPLEX_ENAx bits should always remain '0'. It is intended for the usage when the SIMO pin is used for both TX &amp; RX operations at different times.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 18   | DIS CS TIMERS | 0<br>1 | <p><b>Disable chip-select timers for this format.</b>The C2TDELAY and T2CDELAY timers are by default enabled for all the data format registers. Using this bit, these timers can be disabled for a particular data format, if they are not required. When a master is handling multiple slaves, with varied set-up hold requirement, the application can selectively choose to include or not include the chip-select delay timers for any slaves.</p> <p>Both C2TDELAY and T2CDELAY counts are inserted for the chip selects.</p> <p>No C2TDELAY or T2CDELAY is inserted in the chip select timings.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 17   | POLARITY      | 0<br>1 | <p><b>SPI data format x clock polarity.</b> POLARITYx defines the clock polarity of data format x. The following restrictions apply when switching clock phase and/or polarity:</p> <ul style="list-style-type: none"> <li>In 3-pin/4-pin with nENA pin configuration of a slave SPI, the clock phase and polarity cannot be changed on-the-fly between two transfers. The slave should be reset and reconfigured if clock phase/polarity needs to be switched. In summary, SPI format switching is not fully supported in slave mode.</li> <li>Even while using chip select pins, the polarity of SPICLK can be switched only while the slave is not selected by a valid chip select. The master SPI should ensure that while switching SPICLK polarity, it has deselected all of its slaves. Otherwise, the switching of SPICLK polarity may be incorrectly treated as a clock edge by some slaves.</li> </ul> <p>If POLARITYx is cleared to 0, the SPI clock signal is low-inactive, that is, before and after data transfer the clock signal is low.</p> <p>If POLARITYx is set to 1, the SPI clock signal is high-inactive, that is, before and after data transfer the clock signal is high.</p> |
| 16   | PHASE         | 0<br>1 | <p><b>SPI data format x clock delay.</b> PHASEx defines the clock delay of data format x.</p> <p>If PHASEx is cleared to 0, the SPI clock signal is not delayed versus the transmit/receive data stream. The first data bit is transmitted with the first clock edge and the first bit is received with the second (inverse) clock edge.</p> <p>If PHASEx is set to 1, the SPI clock signal is delayed by a half SPI clock cycle versus the transmit/receive data stream. The first transmit bit has to output prior to the first clock edge. The master and slave receive the first bit with the first edge.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 15-8 | PRESCALE      |        | <p>SPI data format x prescaler. PRESCALEx determines the bit transfer rate of data format x if the SPI is the network master. PRESCALEx is use to derive SPICLK from VCLK. If the SPI is configured as slave, PRESCALEx <b>does not need</b> to be configured. The clock rate for data format x can be calculated as:</p> $BR_{Formatx} = VBUSCLK / (PRESCALEx + 1)$ <p><b>Note: When PRESCALEx is set to 0, the SPI clock rate defaults to VCLK/2.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| 0    | SUSPEND0 | <div>0</div> <div>1</div>                                                                                                    | <p>Transfer suspended / Transfer finished interrupt flag.</p> <p>Every time INTVECT0 is read by the host, the corresponding interrupt flag of the referenced transfer group is cleared and INTVECT0 is updated with the vector coming next in the priority chain.</p> <p>0 The interrupt type is a "transfer finished" interrupt. In other words, the buffer array referenced by INTVECT0 has asserted an interrupt because all of data from the transfer group has been transferred.</p> <p>1 The interrupt type is a "transfer suspended" interrupt. In other words, the transfer group referenced by INTVECT0 has asserted an interrupt because the buffer to be transferred next is in "suspend-to-wait" mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**NOTE:** Reading from the INTVECT0 register when "Transmit Empty" is indicated does not clear the TXINTFLG flag in the SPI Flag Register (SPIFLG). Writing a new word to the SPIDATx register clears the "Transmit Empty" interrupt.

**NOTE:** In multi-buffer mode, INTVECT0 contains the interrupt for the highest priority transfer group. A read from INTVECT0 automatically causes the next-highest priority transfer group's interrupt status to get loaded into INTVECT0 and its corresponding SUSPEND flag to get loaded into SUSPEND0. The transfer group with the lowest number has the highest priority, and the transfer group with the highest number has the lowest priority.

Reading the INTVECT0 register when the RXOVRN interrupt is indicated in multi-buffer mode does not clear the RXOVRN flag and hence does not clear the vector. The RXOVRN interrupt vector may be cleared in multi-buffer mode either by write-clearing the RXOVRN flag in the SPI Flag Register (SPIFLG) or by reading the RXRAM Overrun Buffer Address Register (RXOVRN\_BUF\_ADDR).

### 28.9.23 Interrupt Vector 1 (INTVECT1)

**NOTE:** The TG interrupt is not available in SPI in compatibility mode compatibility mode. Therefore, there is no possibility to access this register in compatibility mode.

| 0    | SUSPEND1 | <div>0</div> <div>1</div>                                                                                  | <div>Transfer suspended / Transfer finished interrupt flag.</div> <div>Every time INTVECT1 is read by the host, the corresponding interrupt flag of the referenced transfer group is cleared and INTVECT1 is updated with the vector coming next in the priority chain.</div> <div>The interrupt type is a "transfer finished" interrupt. In other words, the buffer array referenced by INTVECT1 has asserted an interrupt because all of data from the transfer group has been transferred.</div> <div>The interrupt type is a "transfer suspended" interrupt. In other words, the transfer group referenced by INTVECT1 has asserted an interrupt because the buffer to be transferred next is in "suspend-to-wait" mode.</div>                                                                                                                                                                                                                                                                                             |

**NOTE:** Reading from the INTVECT1 register when "Transmit Empty" is indicated does not clear the TXINTFLG flag in the SPI Flag Register (SPIFLG). Writing a new word to the SPIDATx register clears the "Transmit Empty" interrupt.

**NOTE:** In multi-buffer mode, INTVECT1 contains the interrupt for the highest priority transfer group. A read from INTVECT1 automatically causes the next-highest priority transfer group's interrupt status to get loaded into INTVECT1 and its corresponding SUSPEND flag to get loaded into SUSPEND1. The transfer group with the lowest number has the highest priority, and the transfer group with the highest number has the lowest priority.

Reading the INTVECT1 register when the RXOVRN interrupt is indicated in multi-buffer mode does not clear the RXOVRN flag and hence does not clear the vector. The RXOVRN interrupt vector may be cleared in multi-buffer mode either by write-clearing the RXOVRN flag in the SPI Flag Register (SPIFLG) or by reading the RXOVRN\_BUF\_ADDR register.

### 28.9.24 Parallel/Modulo Mode Control Register (SPIPMCTRL)

**NOTE:** Do not configure MODCLKPOLx and MMODEx bits since this device does not support modulo mode.

**NOTE:** The bits of this register are used in conjunction with the SPIFMTx registers. Each byte of this register corresponds to one of the SPIFMTx registers.

1. Byte0 (Bits 7:0) are used when SPIFMT0 register is selected by DFSEL[1:0] = 00 in the control field of a buffer.
2. Byte1 (Bits 15:8) are used when SPIFMT1 register is selected by DFSEL[1:0] = 01 in the control field of a buffer.
3. Byte2 (Bits 23:16) are used when SPIFMT2 register is selected by DFSEL[1:0] = 10 in the control field of a buffer.
4. Byte3 (Bits 31:24) are used when SPIFMT3 register is selected by DFSEL[1:0] = 11 in the control field of a buffer.

## 28.9.25 Multi-buffer Mode Enable Register (MIBSPIE)

### NOTE: Accessibility of Multi-Buffer RAM

The multi-buffer RAM is not accessible unless the MSPIENA bit set to 1. The only exception to this is in test mode, where, by setting RXRAMACCESS to 1, the multi-buffer RAM can be fully accessed for both read and write.

**Figure 28-54. Multi-buffer Mode Enable Register (MIBSPIE) [offset = 70h]**

|    |          |    |         |
|----|----------|----|---------|

Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 0     | MSPIENA      | 0<br>1 | <p>Multi-buffer mode enable. After power-up or reset, MSPIENA remains cleared, which means that the SPI runs in compatibility mode by default. If multi-buffer mode is desired, this register should be configured first after configuring the SPIGCR0 register. If MSPIENA is not set to 1, the multi-buffer mode registers are not writable.</p> <p>The SPI runs in compatibility mode, that is, in this mode the MibSPI is fully code-compliant to the standard device SPI. No multi-buffered-mode features are supported.</p> <p>The SPI is configured to run in multi-buffer mode.</p>                                                                                                            |

### NOTE: Accessibility of Registers

Registers from this offset address onwards are not accessible in SPI compatibility mode. They are accessible only in the multi-buffer mode.

## 28.9.26 TG Interrupt Enable Set Register (TGITENST)

The register TGITENST contains the TG interrupt enable flags for transfer-finished and for transfer-suspended events. Each of the enable bits in the higher half-word and the lower half-word of TGITENST belongs to one TG.

The register map shown in [Figure 28-55](#) and [Table 28-33](#) represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

**Figure 28-55. TG Interrupt Enable Set Register (TGITENST) [offset = 74h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-33. TG Interrupt Enable Set Register (TGITENST) Field Descriptions**

| Bit   | Field        | Value | Description                                                                                                                                                                                                                       |
|-------|--------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### 28.9.27 TG Interrupt Enable Clear Register (TGITENCR)

The register TGITENCR is used to clear the interrupt enables for the TG-completed interrupt and the TG-suspended interrupts.

The register map shown in [Figure 28-56](#) and [Table 28-34](#) represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

## 28.9.28 Transfer Group Interrupt Level Set Register (TGITLVST)

The register TGITLVST sets the level of interrupts for transfer completed interrupt and for transfer suspended interrupt to level 1.

The register map shown in [Figure 28-57](#) and [Table 28-35](#) represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

**Figure 28-57. Transfer Group Interrupt Level Set Register (TGITLVST) [offset = 7Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-35. Transfer Group Interrupt Level Set Register (TGITLVST) Field Descriptions**

| Bit   | Field         | Value | Description                                                                                                        |
|-------|---------------|-------|--------------------------------------------------------------------------------------------------------------------|
| 31-16 | SET INTLVLRDY |       | Transfer-group completed interrupt level set.                                                                      |

## 28.9.29 Transfer Group Interrupt Level Clear Register (TGITLVCR)

The register TGITLVCR clears the level of interrupts for transfer completed interrupt and for transfer suspended interrupt to level 0.

The register map shown in [Figure 28-58](#) and [Table 28-36](#) represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

**Figure 28-58. Transfer Group Interrupt Level Clear Register (TGITLVCR) [offset = 80h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-36. Transfer Group Interrupt Level Clear Register (TGITLVCR) Field Descriptions**

| Bit   | Field         | Value | Description                                                                                                        |

### 28.9.30 Transfer Group Interrupt Flag Register (TGINTFLG)

The TGINTFLG register comprises the transfer group interrupt flags for transfer-completed interrupts (INTFLGRDYx) and for transfer-suspended interrupts (INTFLGSUSx). Each of the interrupt flags in the higher half-word and the lower half-word of TGINTFLG belongs to one TG.

The register map shown in [Figure 28-59](#) and [Table 28-37](#) represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

**Figure 28-59. Transfer Group Interrupt Flag Register (TGINTFLG) [offset = 84h]**

| 31-16 | INTFLGRDY | <p>0</p> <p>1</p> | <p>Transfer-group interrupt flag for a transfer-completed interrupt.</p> <p><b>Note: Read Clear Behavior.</b> Reading the interrupt vector registers TGINTVECT0 or TGINTVECT1 automatically clears the interrupt flag bit INTFLGRDYx referenced by the vector number given by INTVECT0/INTVECT1 bits, if the SUSPEND[0:1] bit in the vector registers is 0.</p> <p><i>Read:</i> No transfer-completed interrupt occurred since last clearing of the INTFLGRDYx flag.</p> <p><i>Write:</i> A write of 0 to this bit has no effect.</p> <p><i>Read:</i> A transfer finished interrupt from transfer group x occurred. No matter whether the interrupt is enabled or disabled (INTENRDYx = don't care) or whether the interrupt is mapped to INT0 or INT1, INTFLGRDYx is set right after the transfer from TGx is finished.</p> <p><i>Write:</i> The corresponding bit flag is cleared.</p>                   |
| 15-0  | INTFLGSUS | <p>0</p> <p>1</p> | <p>Transfer-group interrupt flag for a transfer-suspend interrupt.</p> <p><b>Note: Read Clear Behavior.</b> Reading the interrupt vector registers TGINTVECT0 or TGINTVECT1 automatically clears the interrupt flag bit INTFLGSUSx referenced by the vector number given by INTVECT0/INTVECT1 bits, if the SUSPEND[0:1] bit in the corresponding vector registers is 1.</p> <p><i>Read:</i> No transfer-suspended interrupt occurred since the last clearing of the INTFLGSUSx flag.</p> <p><i>Write:</i> A write of 0 to this bit has no effect.</p> <p><i>Read:</i> A transfer-suspended interrupt from TGx occurred. No matter whether the interrupt is enabled or disabled (INTENSUSx = don't care) or whether the interrupt is mapped to INT0 or INT1, INTFLGSUSx is set right after the transfer from transfer group x is suspended.</p> <p><i>Write:</i> The corresponding bit flag is cleared.</p> |

### 28.9.31 Tick Count Register (TICKCNT)

One of the trigger sources for TGs is an internal periodic time trigger. This time trigger is called a tick counter and is basically a down-counter with a preload/reload value. Every time the tick counter detects an underflow it reloads the initial value and toggles the trigger signal provided to the TGs.

The trigger signal, shown in Figure 28-60 as a square wave, illustrates the different trigger event types for the TGs (for example, rising edge, falling edge, and both edges).

**Figure 28-60. Tick Counter Operation**

This register is shown in Figure 28-61 and described in Table 28-38.

**Figure 28-61. Tick Count Register (TICKCNT) [offset = 90h]**

| 14-8  | LPEND         | 0-7Fh                          | <b>Last TG end pointer.</b> Usually the TG end address (PEND) is inherently defined by the start value of the starting pointer of the subsequent TG (PSTART). The TG ends one word before the next TG starts (PEND[x]=PSTART[x+1] - 1). For a full configuration of MibSPI, the last TG has no subsequent TG, that is, no end address is defined. Therefore LPEND has to be programmed to specify explicitly the end address of the last TG.<br><b>Note: LPEND allows SW compatibility for MibSPI variants. Because of software compatibility reasons, the last TG end address has to be configurable; otherwise a super-set MibSPI cannot emulate a MibSPI with less TGs without software changes.</b><br><b>Note: The number of transfer groups varies by device, thus the last TG also varies by device.</b> |

### 28.9.33 TGx Control Registers (TGxCTRL)

Each TG can be configured via one dedicated control register. The register description below shows one control register(x) that is identical for all TGs. For example, the control register for TG 2 is named TG2CTRL and is located at *base address + 98h + 4 × 2*. The actual number of available control registers varies by device.

**Figure 28-63. MibSPI TG Control Registers (TGxCTRL) [offsets = 98h-D4h]**

| 30    | ONESHOTx | <p>0 TGx initiates a transfer every time a trigger event occurs and TGENA is set.</p> <p>1 A transfer from TGx will be performed only once (one shot) after a valid trigger event at the selected trigger source. After the transfer is finished the TGENAx control bit will be cleared and therefore no additional transfer can be triggered before the host enables the TG again. This one shot mode ensures that after one group transfer the host has enough time to read the received data and to provide new transmit data.</p>            | <p>Single transfer for TGx.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 29    | PRSTx    | <p>0 If a trigger event occurs during a transfer from TGx, the event is ignored and is not stored internally. The TGx transfer has priority over additional trigger events.</p> <p>1 The TGx pointer (PCURRENTx) will be reset to the start address (PSTARTx) when a valid trigger event occurs at the selected trigger source while a transfer from the same TG is ongoing. Every trigger event resets PCURRENTx no matter whether the concerned TG is in transfer mode or not. The trigger events have priority over the ongoing transfer.</p> | <p>TGx pointer reset mode. Configures the way to resolve trigger events during an ongoing transfer. This bit is meaningful only for level-triggered TGs. Edge-triggered TGs cannot be restarted before their completion by another edge. The PRST bit will have no effect on this behavior.</p> <p><b>Note: When the PRST bit is set, if the buffer being transferred at the time of a new trigger event is a LOCK, CSHOLD or NOBRK buffer, then only after finishing those transfers, the TG will be restarted. This means that even if the TG is retriggered, the TG will only be restarted after finishing the transfer of the first non-LOCK or non-CSHOLD buffer. In the case of the NOBRK buffer, after completing the ICOUNT number of transfers, the TG will be restarted from its PSTART.</b></p> <p>This means that TX control fields such as LOCK and CSHOLD, and DMA control fields such as NOBRK have higher priority over anything else. They have the capability to delay the restart of the TG even if it is retriggered when PRST is 1.</p> |
| 28    | TGTDx    | <p>0 TGx has not been triggered or is no longer waiting for service.</p> <p>1 TGx has been triggered and is either currently being serviced or waiting for servicing.</p>                                                                                                                                                                                                                                                                                                                                                                        | <p>TG triggered.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| 23-20 | TRIGEVTx |       | Type of trigger event. A level-triggered TG can be stopped by de-activating the level trigger. However, the following restrictions apply. <ul style="list-style-type: none"> <li>Deactivating the level trigger for a TG during a NOBRK transfer does not stop the transfers until all of the ICOUNT number of buffers are transferred for the NOBRK buffer. Once a NOBRK buffer is prefetched, the trigger event loses control over the TG until the NOBRK buffer transfer is completed.</li> <li>Once the transfer of a buffer with CSHOLD or LOCK bit set starts, deactivating the trigger level does not stop the transfer until the sequencer completes the transfer of the next non-CSHOLD or non-LOCK buffer in the same TG.</li> <li>Once the last buffer in a TG is pre-fetched, de-activating the trigger level does not stop the transfer group until the last buffer transfer is completed. This means even if the trigger level is deactivated at the beginning of the penultimate (one-before-last) buffer transfer, the sequencer continues with the same TG until it is completed.</li> </ul> |

|       |           | Eh    | EXT13 External trigger source 13. The actual source varies per device (for example, HET I/O channel, event pin).                                                                                                                                                                                                                                                                                                                                          |
|       |           | Fh    | TICK Internal periodic event trigger. The tick counter can initiate periodic group transfers.                                                                                                                                                                                                                                                                                                                                                             |
| 15    | Reserved  | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 14-8  | PSTARTx   | 0-7Fh | <b>TG start address.</b> PSTARTx stores the start address of the corresponding TG. The corresponding end address is inherently defined by the subsequent TG's start address minus one (PENDx[TGx] = PSTARTx[TGx+1]-1). PSTARTx is copied into PCURRENTx when: <ul style="list-style-type: none"> <li>• The TG is enabled.</li> <li>• The end of the TG is reached during a transfer.</li> <li>• A trigger event occurs while PRST is set to 1.</li> </ul> |
| 7     | Reserved  | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 6-0   | PCURRENTx | 0-7Fh | Pointer to current buffer. PCURRENT is read-only. PCURRENTx stores the address (0...127) of the buffer that corresponds to this TG. If the TG switches from active transfer mode to suspend to wait, PCURRENTx contains the address of the currently suspended word. After the TG resumes from suspend to wait mode, the next buffer will be transferred; that is, no buffer data is transferred because of suspend to wait mode.                         |

**NOTE: Register bits vary by device**

TG0 has the highest priority and TG15 has the lowest priority. Under the following conditions a lower priority TG cannot be interrupted by a higher priority TG.

1. When there is a CSHOLD or LOCK buffer, until the completion of the next buffer transfer which is a non-CSHOLD or non-LOCK buffer.
2. An entire sequence of words transferred for a NOBRK DMA buffer.
3. Once the last word in a TG is pre-fetched.

### 28.9.34 DMA Channel Control Register (DMAxCTRL)

Each DMA channel can be configured via one dedicated control register. The register description below shows one exemplary control register that is identical for all DMA channels; for example, the control register for DMA channel 0 is named DMA0CTRL. The MibSPI supports up to 8 bidirectional DMA channels.

The number of bidirectional DMA channels varies by device. The number of DMA channels and hence the number of DMA channel control registers may vary.

**Figure 28-64. DMA Channel Control Register (DMAxCTRL) [offset = D8h-F4h]**

**Table 28-41. DMA Channel Control Register (DMAxCTRL) Field Descriptions**

| Bit   | Field      | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | ONESHOT    | 0<br>1 | Auto-disable of DMA channel after ICOUNT+1 transfers.<br><br>The length of the block transfer is fully controlled by the DMA controller. The enable bits RXDMAENAx and TXDMAENAx are not modified by the MibSPI.<br><br>ONESHOT allows a block transfer of defined length (ICOUNTx+1), mainly controlled by the MibSPI and not by the DMA controller. After ICOUNTx + 1 transfers, the enable bits RXDMAENAx and TXDMAENAx are automatically cleared by the MibSPI, hence no more DMA requests are generated. In conjunction with NOBRKx, a burst transfer can be initiated without any other transfer through another buffer. |
| 30-24 | BUFIDx     | 0-7Fh  | Buffer utilized for DMA transfer. BUFIDx defines the buffer that is utilized for the DMA transfer. In order to synchronize the transfer with the DMA controller with the NOBRK condition the "suspend to wait until..." modes must be used.                                                                                                                                                                                                                                                                                                                                                                                    |
| 23-20 | RXDMA_MAPx | 0-Fh   | Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. One request line for receive data and the other for request line for transmit data. RXDMA_MAPx[3:0] defines the number of the physical DMA Request line that is connected to the receive path of the MibSPI DMA channel.<br><br>If RXDMAENAx and TXDMAENAx are both set to "1", then RXDMA_MAPx[3:0] shall differ from TXDMA_MAPx[3:0] and shall differ from any other used physical DMA Request line. Otherwise unexpected interference may occur.                                                                             |
| 19-16 | TXDMA_MAPx | 0-Fh   | Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. One request line for receive data and the other for request line for transmit data. TXDMA_MAPx[3:0] defines the number of the physical DMA Request line that is connected to the transmit path of the MibSPI DMA channel.<br><br>If RXDMAENAx and TXDMAENAx are both set then TXDMA_MAPx[3:0] shall differ from RXDMA_MAPx[3:0] and shall differ from any other used physical DMA Request line. Otherwise unexpected interference may occur.                                                                                    |
| 15    | RXDMAENAx  | 0<br>1 | Receive data DMA channel enable.<br><br>No DMA request upon new receive data.<br><br>The physical DMA channel for the receive path is enabled. The first DMA request pulse is generated after the first transfer from the referenced buffer (BUFIDx) is finished. The buffer should be configured in as "skip until RXEMPTY is set" or "suspend to wait until RXEMPTY is set" in order to ensure synchronization between the DMA controller and the MibSPI sequencer.                                                                                                                                                          |

**Table 28-41. DMA Channel Control Register (DMAxCTRL) Field Descriptions (continued)**

| Bit  | Field        | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------|--------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14   | TXDAMENAx    | 0<br>1 | Transmit data DMA channel enable.<br>No DMA request upon new transmit data.<br>The physical DMA channel for the transmit path is enabled. The first DMA request pulse is generated right after setting TXDMAENAx to load the first transmit data. The buffer should be configured in the as "skip until TXFULL is set" or "suspend to wait until TXFULL is set" in order to ensure synchronization between the DMA controller and the MibSPI sequencer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 13   | NOBRKx       | 0<br>1 | Non-interleaved DMA block transfer. This bit is available in master mode only.<br><b>Note: Special Conditions during a NOBRK Buffer Transfer. If a NOBRK DMA buffer is currently being serviced by the sequencer, then it is not allowed to be disabled prematurely.</b><br><b>During a NOBRK transfer, the following operations are not allowed:</b> <ul style="list-style-type: none"> <li>• Clearing the NOBRKx bit to 0</li> <li>• Clearing the RXDMAENAx to 0 (if it is already 1)</li> <li>• Clearing the TXDMAENAx to 0 (if it is already 1)</li> <li>• Clearing the BUFMODE[2:0] bits to 000</li> </ul> <b>Any attempts to perform these actions during a NOBRK transfer will produce unpredictable results.</b><br>DMA transfers through the buffer referenced by BUFIDx are interleaved by data transfers from other active buffers or TGs. Every time the sequencer checks the DMA buffer, it performs one transfer and then steps to the next buffer.<br>NOBRKx ensures that ICOUNTx+1 data transfers are performed from the buffer referenced by BUFIDx without a data transfer from any other buffer. The sequencer remains at the DMA buffer until ICOUNTx+1 transfers have been processed. For example, this can be used to generate a burst transfer to one device without disabling the chip select signal in-between (the concerned buffer has to be configured with CSHOLD=1). Another example would be to have a defined block data transfer in slave mode, synchronous to the master SPI.<br><b>Note: Triggering of higher priority TGs or enabling of higher priority DMA channels will not interrupt a NOBRK block transfer.</b> |
| 12-8 | ICOUNTx      | 0-1Fh  | <b>Initial count of DMA transfers.</b> ICOUNTx is used to preset the transfer counter COUNTx[4:0]. Every time COUNTx hits zero it is reloaded with ICOUNTx. The real number of transfers equals ICOUNTx plus one.<br>If ONESHOTx is set, ICOUNTx defines the number of DMA transfers that are performed before the MibSPI automatically disables the DMA channels. If NOBRKx is set, ICOUNTx defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer.<br><b>Note: See <a href="#">Section 28.9.35 (ICOUNT)</a> and <a href="#">Section 28.9.36 (DMACNTLEN)</a> about how to increase the ICOUNT to a 16-bit value. With this extended capability, MibSPI can transfer a block of up to 65535 (65K) words without interleaving (if NOBRK is used) or without deasserting the chipselect between the buffers (if CSHOLD is used).</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 7    | Reserved     | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 6    | COUNT BIT17x |        | The 17th bit of the COUNT field of DMAxCOUNT register.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 5-0  | COUNTx       | 0-3Fh  | Actual number of remaining DMA transfers. This field contains the actual number of DMA transfers that remain, until the DMA channel is disabled, if ONESHOTx is set.<br><b>Note: If the TX and RX DMA requests are enabled, the COUNT register will be decremented when the RX has been serviced.</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### 28.9.35 DMAxCOUNT Register (ICOUNT)

**NOTE:** These registers are used only if the LARGE COUNT bit in the DMACNTLEN register is set.

The number of bidirectional DMA channels varies by device. The number of DMA channels and hence the number of DMA registers varies by device.

**Figure 28-65. DMAxCOUNT Register (ICOUNT) [offset = F8h-114h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-42. MibSPI DMAxCOUNT Register (ICOUNT) Field Descriptions**

| Bit   | Field   | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------|---------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | ICOUNTx | 0-FFFFh | <b>Initial number of DMA transfers.</b> ICOUNTx is used to preset the transfer counter COUNTx. Every time COUNTx hits zero, it is reloaded with ICOUNTx. The real number of transfer equals ICOUNTx plus one. If ONESHOTx is set, ICOUNTx defines the number of DMA transfers that are performed before the MibSPI automatically disables the corresponding DMA channel. If NOBRKx is set, ICOUNTx defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 15-0  | COUNTx  | 0-FFFFh | <p><b>The actual number of remaining DMA transfers.</b>COUNTx Contains the actual number of DMA transfers that remain, until the DMA channel is disabled, if ONESHOTx is set. Since the real counter value is always ICOUNTx +1, the 17th bit of COUNTx is available on DMACTRLx[6] bit.</p> <p><b>Note: Usage Tip for Block Transfer Using a Single DMA Request.</b> It is possible to use the multi-buffer RAM to transfer chunks of data to/from an external SPI. A DMA Controller can be used to handle the data in bursts. Suppose a chunk of 64 bytes of data needs to be transferred and a single DMA request needs to be generated at the end of transferring the 64 bytes. This can be easily achieved by configuring a TG register for the 64 buffer locations and using the DMAxCTRL/DMAxCOUNT registers to configure the last buffer (64th) of the TG as the BUFID and enable RxDMA (NOBRK = 0). At the end of the transfer of the 64th buffer, a DMA request will be generated on the selected DMA request channel. The DMA controller can do a burst read of all 64 bytes from RXRAM and/or then do a burst write to all 64 bytes to the TXRAM for the next chunk.</p> |

| 9-0   | OVERADDR1 | 200-3FFh | <p><b>Uncorrectable parity error address for RXRAM.</b> This register holds the address where a parity error is generated while reading RXRAM. Only the CPU or DMA can read from RXRAM locations. The address captured is byte-aligned. This error address is frozen from being updated until it is read by the CPU. The offset address of RXRAM varies from 200h - 3FFh.</p> <p>The register does not clear its contents during or after module-level reset, system-level reset or even power-up reset.</p> <p>A read operation to this register clears its contents to the default value 200h. After a power-up reset the contents will be unpredictable. A read operation can be performed after power-up to keep the register at its default value, if required. However, the contents of this register are meaningful only when EDFLG1 is set to 1.</p> <p><b>Note: A read of the UERRADDR1 register will clear EDFLG1 in the UERRSTAT register. However, in emulation mode when the SUSPEND signal is high, a read from the UERRADDR1 register does not clear EDFLG1.</b></p> |

| 8-0  | UERRADDR0 | 0-1FFh | <p><b>Uncorrectable parity error address for TXRAM.</b> This register holds the address where a parity error is generated while reading from TXRAM. The TXRAM can be read either by CPU or by the MibSPI sequencer logic for transmission. The address captured is byte-aligned. This error address is frozen from being updated until it is read by the CPU. The offset address of TXRAM varies from 0-1FFh.</p> <p>The register does not clear its contents during or after module-level reset, system-level reset, or even power-up reset.</p> <p>A read operation to this register clears its contents to all 0s. After a power-up reset, the contents of this register will be unpredictable. A read operation can be performed after power-up to clear the this register's contents, if required. However, the contents of this register are meaningful only when EDFLG0 is set to 1.</p> <p><b>Note:</b> A read from the UERRADDR0 register will clear EDFLG0 in the UERRSTAT register. However, in emulation mode when the SUSPEND signal is high, a read from the UERRADDR0 register does not clear EDFLG0.</p> |

#### 28.9.41 RXRAM Overrun Buffer Address Register (RXOVRN BUF ADDR)

In multi-buffer mode, if a particular RXRAM location is written by the MibSPI sequencer logic after the completion of a new transfer when that location already contains valid data, the RX\_OVR bit will be set to 1 while the data is being written. The RXOVRN\_BUF\_ADDR register captures the address of the RXRAM location for which a receiver overrun condition occurred.

**Figure 28-71. RXRAM Overrun Buffer Address Register (RXOVRN BUF ADDR) [offset = 130h]**

| 9-0   | RXOVRN_BUF_ADDR | 200-3FCh | <p><b>Address in RXRAM at which an overwrite occurred.</b> This address value will show only the offset address of the RAM location in the multi-buffer RAM address space. Refer to the device-specific data sheet for the actual absolute address of RXRAM.</p> <p>This word-aligned address can vary from 200h-3FCh. Contents of this register are valid only when any of the INTVECT0 or INTVECT1 and SPIFLG registers show an RXOVRN error vector while in multi-buffer mode. If there are multiple overrun errors, then this register holds the address of first overrun address until it is read.</p> <p><b>Note: Reading this register clears the RXOVRN interrupt flag in the SPIFLG register and the TGINTVECTx.</b></p> <p><b>Note: Receiver overrun errors in multi-buffer mode can be completely avoided by using the SUSPEND until RXEMPTY feature, which can be programmed into each buffer of any TG. However, using the SUSPEND until RXEMPTY feature will make the sequencer wait until the current RXRAM location is read by the VBUS master before it can start the transfer for the same buffer location again. This may affect the overall throughput of the SPI transfer. By enabling the interrupt on RXOVRN in multi-buffer mode, the user can rely on interrupts to know if a receiver overrun has occurred. The address of the overrun in RXRAM is indicated in this RXOVRN_BUF_ADDR register.</b></p> |

### 28.9.42 I/O-Loopback Test Control Register (IOLPBKTSTCR)

This register controls test mode for I/O pins. It also controls whether loop-back should be digital or analog. In addition, it contains control bits to induce error conditions into the module. These are to be used only for module testing.

All of the control/status bits in this register are valid only when the IOLPBKTSTENA field is set to Ah.

**Table 28-49. I/O-Loopback Test Control Register (IOLPBKTSTCR) Field Descriptions**

| Bit   | Field        | Value | Description                                                                                                                                                                                                                                                                                                                                                                                |
|-------|--------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-25 | Reserved     | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                     |
| 24    | SCS FAIL FLG | 0     | Bit indicating a failure on $\overline{\text{SPISCS}}$ pin compare during analog loopback.<br><i>Read:</i> No mismatches occurred on any of the eight chip select pins (vs. the internal chip select number CSNR during transfers).<br><i>Write:</i> Writing a zero to this bit has no effect.                                                                                             |
|       |              | 1     | <i>Read:</i> A comparison between the internal CSNR field and the analog looped-back value of one or more of the $\overline{\text{SPISCS}}[3:0]$ pins failed. A stuck-at fault is detected on one of the $\overline{\text{SPISCS}}[3:0]$ . Comparison is done only on the pins that are configured as functional and during transfer operation.<br><i>Write:</i> This flag bit is cleared. |
| 23-21 | Reserved     | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                     |
| 20    | CTRL BITERR  | 0     | Controls inducing of BITERR during I/O loopback test mode.<br>Do not interfere with looped-back data.                                                                                                                                                                                                                                                                                      |
|       |              | 1     | Induces bit errors by inverting the value of the incoming data during loopback.                                                                                                                                                                                                                                                                                                            |
| 19    | CTRL DESYNC  | 0     | Controls inducing of the desync error during I/O loopback test mode.<br>Do not cause a desync error.                                                                                                                                                                                                                                                                                       |
|       |              | 1     | Induce a desync error by forcing the incoming $\overline{\text{SPIENA}}$ pin (if functional) to remain 0 even after the transfer is complete. This forcing will be retained until the kernel reaches the idle state.                                                                                                                                                                       |
| 18    | CTRL PARERR  | 0     | Controls inducing of the parity errors during I/O loopback test mode.<br>Do not cause a parity error.                                                                                                                                                                                                                                                                                      |
|       |              | 1     | Induce a parity error by inverting the polarity of the parity bit.                                                                                                                                                                                                                                                                                                                         |
| 17    | CTRL TIMEOUT | 0     | Controls inducing of the timeout error during I/O loopback test mode.<br>Do not cause a timeout error.                                                                                                                                                                                                                                                                                     |
|       |              | 1     | Induce a timeout error by forcing the incoming $\overline{\text{SPIENA}}$ pin (if functional) to remain 1 when transmission is initiated. The forcing will be retained until the kernel reaches the idle state.                                                                                                                                                                            |

**Table 28-49. I/O-Loopback Test Control Register (IOLPBKTSTCR) Field Descriptions (continued)**

| Bit   | Field            | Value                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### 28.9.43 SPI Extended Prescale Register 1 (EXTENDED\_PRESCALE1 for SPIFMT0 and SPIFMT1)

This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This is an extension of SPIFMT0 and SPIFMT1 registers. For example, EPRESCALE\_FMT1(7:0) of EXTENDED\_PRESCALE1 and PRESCALE1(7:0) of SPIFMT1 register will always reflect the same contents. Similarly EPRESCALE\_FMT0(7:0) and PRESCALE0(7:0) of SPIFMT0 reflect the same contents.

**Figure 28-73. SPI Extended Prescale Register 1 (EXTENDED\_PRESCALE1 for SPIFMT0 and SPIFMT1) [offset = 138h]**

**Table 28-50. SPI Extended Prescale Register 1 (EXTENDED\_PRESCALE1) Field Descriptions**

| Bit   | Field          | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------|----------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-27 | Reserved       | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 26-16 | EPRESCALE_FMT1 | 0-7FFh | <p>EPRESCALE_FMT1. Extended Prescale value for SPIFMT1. EPRESCALE_FMT1 determines the bit transfer rate of data format 1 if the SPI/MibSPI is the network master. EPRESCALE_FMT1 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT1 <b>does not need</b> to be configured. These EPRESCALE_FMT1(7:0) bits and PRESCALE1(7:0) bits of SPIFMT1 register will point to the same physically implemented register. The clock rate for data format 1 can be calculated as:</p> $BR_{Format1} = VBUSPCLK / (EPRESCALE_FMT1 + 1)$ <p><i>Write:</i> This register field should be written if a SPICLK prescaler of more VBUSPCLK/256 is required. This field provides a prescaler of up to VBUSPCLK/2048 for SPICLK. Writing to this register field will also get reflected in SPIFMT1(15:8).</p> <p><i>Read:</i> Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE1(26:16) or SPIFMT1(15:8) register.</p> <p><b>Note:</b> If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE1 register is programmed after SPIFMT1 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE1 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE1 field of SPIFMT1 will automatically clear EPRESCALE_FMT1(10:8) bits to '000' so that the integrity of PRESCALE value is maintained.</p> |

| 10-0 | EPRESCALE_FMT0 | 0-7FFh | <p>EPRESCALE_FMT0. Extended Prescale value for SPIFMT0. EPRESCALE_FMT0 determines the bit transfer rate of data format 0 if the SPI/MibSPI is the network master. EPRESCALE_FMT0 is used to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT0 <b>does not need</b> to be configured. These EPRESCALE_FMT0(7:0) bits and PRESCALE0(7:0) bits of SPIFMT0 register will point to the same physically implemented register. The clock rate for data format 0 can be calculated as:</p> $BR_{Format0} = VBUSPCLK / (EPRESCALE_FMT0 + 1)$ <p><i>Write:</i> This register field should be written if a SPICLK prescaler of more than VBUSPCLK/256 is required. This field provides a prescaler of up to VBUSPCLK/2048 for SPICLK. Writing to this register field will also get reflected in SPIFMT0(15:8).</p> <p><i>Read:</i> Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE0(10:0) or SPIFMT0(15:8) register.</p> <p><b>Note:</b> If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE1 register is programmed after SPIFMT0 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE1 register when a prescale of more than 256 is intended on SPICLK. Writing to PRESCALE0 field of SPIFMT0 will automatically clear EPRESCALE_FMT0(10:8) bits to '000' so that the integrity of PRESCALE value is maintained.</p> |

### 28.9.44 SPI Extended Prescale Register 2 (EXTENDED\_PRESCALE2 for SPIFMT2 and SPIFMT3)

This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This is an extension of SPIFMT2 and SPIFMT3 registers. For example, EPRESCALE\_FMT3(7:0) of EXTENDED\_PRESCALE2 and PRESCALE3(7:0) of SPIFMT3 register will always reflect the same contents. Similarly EPRESCALE\_FMT2(7:0) and PRESCALE2(7:0) of SPIFMT2 reflect the same contents.

**Table 28-51. SPI Extended Prescale Register 2 (EXTENDED\_PRESCALE2) Field Descriptions**

| Bit   | Field          | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|----------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-27 | Reserved       | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 26-16 | EPRESCALE_FMT3 | 0-7FFh | <p>EPRESCALE_FMT3. Extended Prescale value for SPIFMT1. EPRESCALE_FMT1determines the bit transfer rate of data format 3 if the SPI/MibSPI is the network master. EPRESCALE_FMT3 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT3 <b>does not need</b> to be configured. These EPRESCALE_FMT3(7:0) bits and PRESCALE3(7:0) bits of SPIFMT1 register will point to the same physically implemented register. The clock rate for data format 1 can be calculated as:</p> $BR_{Format3} = VBUSPCLK / (EPRESCALE_FMT3 + 1)$ <p><i>Write:</i> This register field should be written if a SPICLK prescaler of more VBUSPCLK/256 is required. This field provides a prescaler of up to VBUSPCLK/2048 for SPICLK. Writing to this register field will also get reflected in SPIFMT3(15:8).</p> <p><i>Read:</i> Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE3(26:16) or SPIFMT3(15:8) register.</p> <p><b>Note:</b> If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE2 register is programmed after SPIFMT3 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE2 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE3 field of SPIFMT3 will automatically clear EPRESCALE_FMT3(10:8) bits to '000' so that the integrity of PRESCALE value is maintained.</p> |

| 10-0 | EPRESCALE_FMT2 | 0-7FFh | <p>EPRESCALE_FMT2. Extended Prescale value for SPIFMT2. EPRESCALE_FMT0 determines the bit transfer rate of data format 2 if the SPI/MibSPI is the network master. EPRESCALE_FMT2 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT2 <b>does not need</b> to be configured. These EPRESCALE_FMT2(7:0) bits and PRESCALE2(7:0) bits of SPIFMT2 register will point to the same physically implemented register. The clock rate for data format 0 can be calculated as:</p> $BR_{Format2} = VBUSPCLK / (EPRESCALE_FMT2 + 1)$ <p><i>Write:</i> This register field should be written if a SPICLK prescaler of more VBUSPCLK/256 is required. This field provides a prescaler of up to VBUSPCLK/2048 for SPICLK. Writing to this register field will also get reflected in SPIFMT2(15:8).</p> <p><i>Read:</i> Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE2(10:0) or SPIFMT2(15:8) register.</p> <p><b>Note:</b> If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE2 register is programmed after SPIFMT2 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE2 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE2 field of SPIFMT2 will automatically clear EPRESCALE_FMT2(10:8) bits to '000' so that the integrity of PRESCALE value is maintained.</p> |

## 28.10 Multi-Buffer RAM

The multi-buffer RAM is used for holding transit & received data, control and status information. The multi-buffer RAM contains two banks of up to 128 32-bit words for a maximum configuration. One bank (TXRAM) contains entries for transmit data (replicating the SPIDAT1 register). The other bank (RXRAM) contains received data (replicating the SPIBUF register). The buffers can be partitioned into multiple TGs, each containing a programmable number of buffers. Each of the buffers can be subdivided into 16-bit transmit field, 16-bit receive field, 16-bit control field, and 16-bit status field, as displayed in [Figure 28-75](#). A 4-bit parity field per word is also included in each bank of RAM.

**Figure 28-75. Multi-Buffer RAM Configuration**

All fields can be read and written with 8-bit, 16-bit, or 32-bit accesses.

The transmit fields can be written and read in the address range 000h to 1FFh. The transmit words contain data and control fields.

The receive RAM fields are read-only and can be accessed through the address range 200h to 3FCh. The receive words contain data and status fields.

The chip select number bit field CSNR[7:0] of the control field for a given word is mirrored into the corresponding receive-buffer status field after transmission.

The Parity is automatically calculated and copied to Parity location

**NOTE:** Please refer to the specific device datasheet for the actual number of transmit and receive buffers.

Write to unimplemented buffer is overwriting the corresponding implemented buffer. In MIBSPI, if the RAM SIZE specified is 32 buffers, write to 33rd buffer overwrites 1st buffer, write to 34th buffer overwrites 2st buffer and so on.

### 28.10.1 Multi-Buffer RAM Auto Initialization

When the MIBSPI is out of reset mode, auto initialization of multi-buffer RAM starts. The application code must check for BUFINITACTIVE bit to be '0' (Multibuffer RAM initialization is complete) before configuring multi-buffer RAM.

Besides the default auto initialisation after reset, the auto-initialization sequence can also be done in following ways:

1. Enable the global hardware memory initialization key by programming a value of 1010b to the bits [3:0] of the MINITGCR register of the System module.
2. Set the control bit for the multi-buffer RAM in the MSINENA System module register. This bit is device-specific for each memory that support auto-initialization. Please refer to the device datasheet to identify the control bit for the multi-buffer RAM. This starts the initialization process. The BUFINITACTIVE bit will get set to reflect that the initialization is ongoing.
3. When the memory initialization is completed, the corresponding status bit in the MINISTAT register will be set. Also, the BUFINITACTIVE bit will get cleared.
4. Disable the global hardware memory initialization key by programming a value of 0101 to the bits [3:0] of the MINITGCR register of the System module.

Please refer to the Architecture User Guide for more details on the memory auto-initialization process.

---

**NOTE:** During Auto Initialization process, all the Multibuffer mode registers (except MIBSPIE) will be reset to their default values. So, it should be ensured that Auto Initialization is completed before configuring the Multibuffer mode registerse.

---

### 28.10.2 Multi-buffer RAM Register Summary

This section describes the Multi-buffer RAM control and transmit-data fields of each word of TXRAM, and the status and receive-data fields of each word of RXRAM. The offset of the multi-buffer RAM is FF0E 0000h.

**Table 28-52. Multi-buffer RAM Register Summary**

| Offset          | Acronym | Register Description                     | Section                         |
|-----------------|---------|------------------------------------------|---------------------------------|
| Base + 000-1FFh | TXRAM   | Multi-buffer RAM Transmit Data Register  | <a href="#">Section 28.10.3</a> |
| Base + 200-3FFh | RXRAM   | Multi-buffer RAM Receive Buffer Register | <a href="#">Section 28.10.4</a> |

### 28.10.3 Multi-buffer RAM Transmit Data Register

Each word of TXRAM is a transmit-buffer register.

**Figure 28-76. Multi-buffer RAM Transmit Data Register [offset = Base + 000-1FFh]**

**Table 28-53. Multi-buffer RAM Transmit Data Register Field Descriptions**

| Bit   | Field   | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-29 | BUFMODE | <p>0 <b>disabled.</b> The buffer is disabled</p> <p>1h <b>skip single-transfer mode.</b> Skip this buffer until the corresponding TXFULL flag is set (new transmit data is available).</p> <p>2h <b>skip overwrite-protect mode.</b> Skip this buffer until the corresponding RXEMPTY flag is set (new receive data can be stored in RXDATA without data loss).</p> <p>3h <b>skip single-transfer overwrite-protect mode.</b> Skip this buffer until both of the corresponding TXFULL and RXEMPTY flags are set. (new transmit data available and previous data received by the host).</p> <p>4h <b>continuous mode.</b> Initiate a transfer each time the sequencer checks this buffer. Data words are retransmitted if the buffer has not been updated. Receive data is overwritten, even if it has not been read.</p> <p>5h <b>suspend single-transfer mode.</b> Suspend-to-wait until the corresponding TXFULL flag is set (the sequencer stops at the current buffer until new transmit data is written in the TXDATA field).</p> <p>6h <b>suspend overwrite-protect mode.</b> Suspend-to-wait until the corresponding RXEMPTY flag is set (the sequencer stops at the current buffer until the previously-received data is read by the host).</p> <p>7h <b>suspend single-transfer overwrite-protect mode.</b> Suspend-to-wait until the corresponding TXFULL and RXEMPTY flags are set (the sequencer stops at the current buffer until new transmit data is written into the TXDATA field and the previously-received data is read by the host).</p> | <p>Specify conditions that are recognized by the sequencer to initiate transfers of each buffer word.</p> <p>When one of the "skip" modes is selected, the sequencer checks the buffer status every time it reads from this buffer. If the current buffer status (TXFULL, RXEMPTY) does not match, the buffer is skipped without a data transfer.</p> <p>When one of the "suspend" modes is selected, the sequencer checks the buffer status when it reads from this buffer. If TXFULL and/or RXEMPTY do not match, the sequencer waits until a match occurs. No data transfer is initiated until the status condition of this buffer changes.</p> |
| 28    | CSHOLD  | <p>0 The chip select signal is deactivated at the end of a transfer after the T2CDELAY time has passed. If two consecutive transfers are dedicated to the same chip select this chip select signal will be deactivated for at least 2VCLK cycles before it is activated again.</p> <p>1 The chip select signal is held active at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1. If the new chip select number equals the previous one, the active chip select signal is extended until the end of transfer with CSHOLD cleared, or until the chip-select number changes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | <p>Chip select hold mode. The CSHOLD bit is supported in master mode only in compatibility-mode of MibSPI, (it is ignored in slave mode). CSHOLD defines the behavior of the chip select line at the end of a data transfer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 27    | LOCK    | <p>0 Any higher-priority TG can begin at the end of the current transaction.</p> <p>1 A higher-priority TG cannot occur until after the next unlocked buffer word is transferred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <p>Lock two consecutive buffer words. Do not allow interruption by TG's with higher priority.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Table 28-53. Multi-buffer RAM Transmit Data Register Field Descriptions (continued)**

| Bit   | Field  | Value               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|--------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26    | WDEL   | 0<br><br>1          | <p>Enable the delay counter at the end of the current transaction.</p> <p>Note: The WDEL bit is supported in master mode only. In slave mode, this bit will be ignored.</p> <p>No delay will be inserted. However, SPISCS pins will still be de-activated for at least for 2VCLK cycles if CSHOLD = 0.</p> <p>Note: The duration for which the SPISCS pin remains deactivated also depends upon the time taken to supply a new word after completing the shift operation (in compatibility mode). If TXBUF is already full, then the SPISCS will be deasserted for at least two VCLK cycles (if WDEL = 0).</p> <p>After a transaction, WDELAY of the corresponding data format will be loaded into the delay counter. No transaction will be performed until the WDELAY counter overflows. The SPISCS pins will be de-activated for at least (WDELAY + 2) × VCLK_Period duration.</p> |

| 32-16 | CSNR   | 0-FFh               | <p>Chip select number. CSNR defines the chip-select that will be activated during the data transfer.</p> <p><b>Note: 1) Writing to only the control field (using byte writes) does not initiate any SPI transfer in master mode. This feature can be used to set up SPICLK phase or polarity before actually starting the transfer by only updating the DFSEL fields in the control field to select the required phase/polarity combination.</b></p> <p><b>Note: 2) Bits [23:20] is not writable in the device due to non availability of Chip select pins CS[4:7].</b></p>                                                                                                                                                                                                                                                                                                           |
| 15-0  | TXDATA | 0-7FFFh             | <p><b>Transfer data.</b> When written, these bits are copied to the shift register if it is empty. If the shift register is not empty, then they are held in TXBUF.</p> <p>SPIEN must be set to 1 before this register can be written to. Writing a 0 to SPIEN forces the lower 16 bits of SPIDAT1 to 0.</p> <p>Write to this register ONLY when using the automatic slave chip-select feature (see <a href="#">Section 28.2</a> for more information). A write to this register will drive the contents of CSNR[7:0] on the SPISCS[3:0] pins, if they are configured as functional pins.</p> <p>When this register is read, the contents of TXBUF, which holds the latest data written, will be returned.</p> <p><b>Note: Regardless of the character length, the transmit data should be right-justified before writing to the SPIDAT1 register.</b></p>                            |

### 28.10.4 Multi-buffer RAM Receive Buffer Register

Each word of RXRAM is a receive-buffer register.

**Table 28-54. Multi-buffer Receive Buffer Register Field Descriptions**

| Bit | Field   | Value             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----|---------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31  | RXEMPTY | <p>0</p> <p>1</p> | <p><b>Receive data buffer empty.</b>When the host reads the SPIBUF field or the entire SPIBUF register, it automatically sets the RXEMPTY flag. When a data transfer is completed, the received data is copied into SPIBUF, and the RXEMPTY flag is cleared.</p> <p>New data has been received and copied into the SPIBUF field.</p> <p>No data has been received since the last read of SPIBUF.</p> <p>This flag gets set to 1 under the following conditions:</p> <ul style="list-style-type: none"> <li>Reading the RXDATA portion of the SPIBUF register.</li> <li>Writing a 1 to clear the RXINTFLG bit in the SPI Flag Register (SPIFLG).</li> </ul> <p>Write-clearing the RXINTFLG bit before reading the SPIBUF indicates the received data is being ignored. Conversely, RXINTFLG can be cleared by reading the RXDATA portion of SPIBUF (or the entire register).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 30  | RXOVR   | <p>0</p> <p>1</p> | <p><b>Receive data buffer overrun.</b> When a data transfer is completed and the received data is copied into RXBUF while it is already full, RXOVR is set. Overruns always occur to RXBUF, not to SPIBUF; the contents of SPIBUF are overwritten only after it is read by the Peripheral (VBUSP) master (CPU, DMA, or other host processor).</p> <p>If enabled, the RXOVRN interrupt is generated when RXBUF is overwritten, and reading either SPI Flag Register (SPIFLG) or SPIVEXTx shows the RXOVRN condition. Two read operations from the SPIBUF register are required to reach the overwritten buffer word (one to read SPIBUF, which then transfers RXDATA into SPIBUF for the second read).</p> <p>This flag is cleared to 0 when the RXDATA is read.</p> <p><b>Note: A special condition under which RXOVR flag gets set. If both SPIBUF and RXBUF are already full and while another buffer receive is underway, if any errors such as TIMEOUT, BITERR and DLEN_ERR occur, then RXOVR in RXBUF and SPI Flag Register (SPIFLG) registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receive overrun.</b></p> <p>0 No receive data overrun condition occurred since last read of the data field.</p> <p>1 A receive data overrun condition occurred since last read of the data field.</p> |
| 29  | TXFULL  | <p>0</p> <p>1</p> | <p><b>Transmit data buffer full.</b>This flag is a read-only flag. Writing into the SPIDAT0 or SPIDAT1 field while the TX shift register is full will automatically set the TXFULL flag. Once the word is copied to the shift register, the TXFULL flag will be cleared. Writing to SPIDAT0 or SPIDAT1 when both TXBUF and the TX shift register are empty does not set the TXFULL flag.</p> <p>0 The transmit buffer is empty; SPIDAT0/SPIDAT1 is ready to accept a new data.</p> <p>1 The transmit buffer is full; SPIDAT0/SPIDAT1 is not ready to accept new data.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 28-54. Multi-buffer Receive Buffer Register Field Descriptions (continued)**

| Bit   | Field     | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| 28    | BITERR    | 0       | <b>Bit error.</b> There was a mismatch of internal transmit data and transmitted data.<br><br>No bit error occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|       |           | 1       | <b>Note: This flag is cleared to 0 when the RXDATA portion of the SPIBUF register is read.</b><br><br>A bit error occurred. The SPI samples the signal of the transmit pins (master: SIMOx, slave: SOMIx) at the receive point (one-half clock cycle after the transmit point). If the sampled value differs from the transmitted value, a bit error is detected and the BITERR flag is set. Possible reasons for a bit error include noise, an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 27    | DESYNC    | 0       | <b>Desynchronization of slave device.</b> This bit is valid in master mode only.<br><br>The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus $t_{2EDELAY}$ . If DESYNCENA is set, an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.<br><br><b>Note: In the Compatibility Mode MibSPI, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is because the receive completion flag/interrupt is generated when the buffer transfer is completed. But desynchronization is detected after the buffer transfer is completed. So, if the VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. In multi-buffer mode, the desync flag is always guaranteed to be for the current buffer.</b> |
|       |           | 1       | No slave desynchronization detected.<br><br><b>Note: This flag is cleared to 0 when the RXDATA portion of the SPIBUF register is read.</b><br><br>A slave device is desynchronized.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 26    | PARITYERR | 0       | <b>Parity error.</b> The calculated parity differs from the received parity bit.<br><br>If the parity generator is enabled (selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word, the parity generator calculates the reference parity and compares it to the received parity bit. If a mismatch is detected, the PARITYERR flag is set.<br><br><b>Note: This flag is cleared to 0 when the RXDATA portion of the SPIBUF register is read.</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

It contains the chip select number that was activated during the last word transfer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 15-0  | RXDATA    | 0-FFFFh | <b>SPI receive data.</b> This is the received word, transferred from the receive shift-register at the end of a transfer. Regardless of the programmed character length and the direction of shifting, the received data is stored right-justified in the register.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## 28.11 Parity Memory

The parity portion of multi-buffer RAM is not accessible by the CPU during normal operating modes. However, each read or write operation to the control/data/status portion of the multi-buffer RAM causes reads/writes to the parity portion as well.

- Each write to the multi-buffer RAM (either from the Peripheral interface or by the MibSPI itself) causes a write operation to the parity portion of RAM simultaneously to update the equivalent parity bits.
- Each read operation from the multi-buffer RAM (either from the Peripheral interface or by the MibSPI itself) causes a read operation from the parity portion of the RAM for parity comparison purpose.
- Reads/Writes to multi-buffer RAM can either be caused by any CPU/DMA accesses or by the sequencer logic of MibSPI itself.
- In case of Parity error ESM module is notified to generate MIBSPI Parity ESM interrupt. User can check the error status and address location captured in the UERRSTAT and UERRADDRx registers respectively.

For testing the parity portion of the multi-buffer RAM, which is a 4-bit field per word address (1 bit per byte), a separate parity memory test mode is available. Parity memory test mode can be enabled and disabled by the PTESTEN bit in the UERRCTRL register.

During the parity test mode, the parity locations are addressable at the address between RAM\_BASE\_ADDR + 0x400h and RAM\_BASE\_ADDR + 0x7FFh. Each location corresponds, sequentially, to each TXRAM word, then to each RXRAM word. See [Figure 28-78](#) for a diagram of the memory map of parity memory during normal operating mode and during parity test mode.

During parity test mode, after writing the data/control portion of the RAM, the parity locations can be written with incorrect parity bits to intentionally cause parity errors.

See the device-specific data sheet to get the actual base address of the multi-buffer RAM.

---

**NOTE:** The RX\_RAM\_ACCESS bit can also be set to 1 during the parity test mode to be able writes to RXRAM locations. Both parity RAM testing and RXRAM testing can be done together.

---

There are 4 bits of parity corresponding to each of the 32-bit multi-buffer locations. Individual bits in the parity memory are byte-addressable in parity test mode. See the example in [Figure 28-79](#) for further details.

---

**NOTE:** Polarity of the parity (odd/even) varies by device. In some devices, a control register in the system module can be used to select odd or even parity.

---

**Figure 28-78. Memory Map for Parity Locations during Normal and Test Mode**

### 28.11.1 Example of Parity Memory Organization

Suppose TXBUF5 (6th location in TXRAM) in the multi-buffer RAM is written with a value of A001\_AA55. If the polarity of the parity is set to odd, the corresponding parity location parity5 will get updated with equivalent parity of 1011 in its field.

During parity-memory test mode, these bits can be individually byte addressed. The return data will be a byte adjusted with actual parity bit in the LSB of the byte. If a word is read from the word-boundary address of parity locations, then each bit of the 4-bit parity is byte-adjusted and a 32-bit word is returned. 0s will be padded into the parity bits to get each byte. See Figure 28-79 for a diagram.

**Figure 28-79. Example of Memory Mapped Parity Locations during Test Mode**

1 Shaded areas indicate reads return 0, writes have no effect. These registers are not physically present.

#### NOTE: Read Access to Parity Memory Locations

Parity memory locations can be read even without entering into parity memory test mode. Their address remains as in memory test mode. It is only to enter parity-memory test mode to enable write access to the parity memory locations.

## 28.12 MibSPI Pin Timing Parameters

The pin timings of SPI can be classified based on its mode of operation. In each mode, different configurations like Phase & Polarity affect the pin timings.

The pin directions are based on the mode of operation.

### Master mode SPI:

- SPICLK (SPI Clock) - Output
- SPISIMO (SPI Slave In Master Out) - Output
- $\overline{\text{SPISCS}}[7:0]$  (SPI Slave Chip Selects) - Output
- SPISOMI (SPI Slave Out Master In) - Input
- $\overline{\text{SPIENA}}$  (SPI slave ready Enable) - Input

### Slave mode SPI:

- SPICLK - Input
- SPISIMO - Input
- $\overline{\text{SPISCS}}$  - Input
- SPISOMI - Output
- $\overline{\text{SPIENA}}$  - Output

**NOTE:** All the timing diagrams given below are with Phase='0' & Polarity = '0' unless explicitly stated otherwise.

### 28.12.1 Master Mode Timings for SPI/MibSPI

**Figure 28-80. SPI/MibSPI Pins during Master mode 3-pin configuration**

**Figure 28-81. SPI/MibSPI pins during Master mode 4-pin with  $\overline{\text{SPISCS}}$  configuration.**

**Figure 28-82. SPI/MibSPI pins during Master mode in 4pin with  $\overline{\text{SPIENA}}$  configuration**

**Figure 28-83. SPI/MibSPI pins during Master/Slave mode with 5-pin configuration**

## 28.12.2 Slave Mode Timings for SPI/MibSPI

**Figure 28-84. SPI/MibSPI pins during Slave mode 3-pin configuration**

**Figure 28-85. SPI/MibSPI pins during Slave mode in 4pin with  $\overline{\text{SPIENA}}$  configuration**

**Figure 28-86. SPI/MibSPI pins during Slave mode in 5pin configuration - (Single Slave).**

**Figure 28-87. SPI/MibSPI pins during Slave mode in 5pin configuration - (Single/Multi Slave).**

### 28.12.3 Master Mode Timing Parameter Details

In case of Master, the module drives out SPICLK. It also drives out the Transmit data on SPISIMO w.r.t its internal SPICLK. In case of Master mode, the RX data on SPISOMI pin is registered w.r.t SPICLK received through Input buffer from the I/O pad.

If ChipSelect pin is functional, then Master will drive out  $\overline{\text{SPISCS}}$  pin(s) before starting the SPICLK. If  $\overline{\text{SPIENA}}$  pin is functional, then Master will wait for an active 'low' from Slave on the input pin to start the SPICLK.

**Table 28-55. Timing Parameters of SPI/MibSPI Pins in Master Mode**

| SI No. | Delay Item                                                                                        | Min                    | Max                                        | Note                                                                                                                                                                                                                                                              |

|-----------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|------------------------------------------------|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12                                                                                                                                | Maximum hold time on $\overline{\text{SPIEN}}_A$ after the final SPICLK edge supported by Master (Phase = '0') | -                                              | $0.5\text{SPICLK} + (\text{WDELAY} + 1)^* \text{VCLK}$ | After the last edge of SPICLK, the maximum delay within which $\overline{\text{SPIEN}}_A$ pin should be deasserted so that the Master does not start the next buffer (if available) transfer. Slave SPI/MibSPI should deassert $\overline{\text{SPIEN}}_A$ before this time if it is not ready with the next TX data for transfer. |
| 13                                                                                                                                | Maximum hold time on $\overline{\text{SPIEN}}_A$ after the final SPICLK edge supported by Master (Phase = '1') | -                                              | $(\text{WDELAY} + 1)^* \text{VCLK}$                    | After the last edge of SPICLK, the maximum delay within which $\overline{\text{EN}}_A$ pin should be deasserted so that the Master does not start the next buffer (if available) transfer. Slave SPI/MibSPI should deassert $\overline{\text{SPIEN}}_A$ before this time if it is not ready with the next TX data for transfer.    |
| 14a                                                                                                                               | Minimum inactive time of $\overline{\text{SPISCS}}$ pin(s) between two data words (CSHOLD=0)                   | $2\text{VCLK} + (\text{WDELAY})^* \text{VCLK}$ | -                                                      | This can be increased by using WDELAY counter. Applicable when CSHOLD is '0' for the current and the previous buffer transfers.                                                                                                                                                                                                    |
| 14b                                                                                                                               | Minimum inactive time of $\overline{\text{SPISCS}}$ pin(s) between two data words (CSHOLD=1)                   | $1\text{VCLK} + (\text{WDELAY})^* \text{VCLK}$ | -                                                      | This can be increased by using WDELAY counter. This is applicable when CSHOLD is set to '1' for the current buffer and was '0' for the previous one.                                                                                                                                                                               |
| 15                                                                                                                                | Time at which $\overline{\text{SPIEN}}_A$ pin will be sampled after $\overline{\text{SPISCS}}$ goes active     | C2TDELAY                                       | -                                                      | If C2TDELAY is not programmed or '0', then the FSM will look for the $\overline{\text{EN}}_A$ pin value 1VCLK after the asserting the ChipSelect. The FSM always looks at the registered version of $\overline{\text{EN}}_A$ pin value.                                                                                            |
| $t_{dd}$ - delay differences between the two related pins; $t_{pdd}$ - propagation delay differences between the two related pins |                                                                                                                |                                                |                                                        |                                                                                                                                                                                                                                                                                                                                    |

### 28.12.4 Slave Mode Timing Parameter Details

In case of Slave mode, the module will drive only SPISOMI and SPIENA pins. All other pins are inputs to it. The RX data on SPISIMO pin will be registered w.r.t SPICLK pin. Slave will use  $\overline{\text{SPISCS}}$  pin to drive out SPIENA pin if both are functional. If 4pin with SPIENA is configured, then Slave will drive out active low signal on SPIENA pin when a new data is written to the TX Shift Register. Irrespective of 4pin with SPIENA or 5pin configuration, the Slave will deassert the SPIENA pin after the last bit is received. If ENABLE\_HIGHZ (SPIINT0.24) bit is '0', the de-asserted value of  $\overline{\text{SPIENA}}$  pin will be '1'. Otherwise, it will depend upon the internal PullUp or PullDown resistor (if implemented) depending upon the Specification of the Chip.

**Table 28-56. Timing Parameters of SPI/MibSPI Pins in Slave Mode.**

| SI No. | Delay Item                                                                                                                   | Min                     | Max             | Note                                                                                                                                                                             |
|--------|------------------------------------------------------------------------------------------------------------------------------|-------------------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1      | Cycle Time of SPICLK                                                                                                         | 2VCLK                   | -               | Slave supports any slower frequency of SPICLK above DC levels.                                                                                                                   |
| 4      | Output Delay time, SPICLK TX edge to SPISOMI valid                                                                           | $t_{pd}$                | -               | Actual delay depends on the propagation delay of SPICLK pin to the Clock input of the register driving the TXDATA and the O/P buffer delay on SPISOMI pin.                       |
| 5      | Output Hold time, SPICLK RX edge to SPISOMI valid                                                                            | 0.5SPICLK<br>+ $t_{pd}$ | -               | Actual delay depends on the propagation delay of SPICLK pin to the Clock input of the register driving the TXDATA and the O/P buffer delay on SPISOMI pin.                       |
| 6      | Input Setup time requirement on SPISIMO pin with respect to (w.r.t) SPICLK                                                   | +/- $t_{pdd}$           | -               | The incoming data on SPISIMO pin is sampled w.r.t incoming SPICLK. So, the difference between propagation delay ( $t_{pdd}$ ) of both the pins determines the actual setup time. |
| 7      | Input Hold time requirement on SPISIMO pin w.r.t SPICLK                                                                      | +/- $t_{pdd}$           | -               | The incoming data on SPISIMO pin is sampled w.r.t incoming SPICLK. So, the difference between propagation delay ( $t_{pdd}$ ) of both the pins determines the actual hold time.  |
| 16     | SPICLK - $\overline{\text{SPIENA}}$<br>(4pin/5pin configuration)                                                             | 1VCLK                   | 2.5 VCLK        | Delay between the final RX-edge of SPICLK to the deassertion of $\overline{\text{SPIENA}}$ pin by the Slave                                                                      |
| 17     | $\overline{\text{SPISCS}}$ - $\overline{\text{SPIENA}}$<br>(5pin)                                                            | 0                       | -               | Delay between assertion of $\overline{\text{SPISCS}}$ by the Master to the assertion of $\overline{\text{SPIENA}}$ pin by the Slave (assuming Slave is ready with the TX data).  |
| 18     | Minimum delay between<br>deselecting the Slave using its<br>$\overline{\text{SPISCS}}$ pin and clocking a different<br>Slave | 2VCLK                   | -               | A SPICLK edge within 2VCLK of deassertion of $\overline{\text{SPISCS}}$ will be treated a valid edge in Slave mode.                                                              |
| 19     | $\overline{\text{SPISCS}}$ deassertion to SPISOMI<br>tristate                                                                | -                       | 1VCLK+ $t_{pd}$ | Slave will tristate the SPISOMI pin if it is deselected by $\overline{\text{SPISCS}}$ (when CS is functional).                                                                   |

## Serial Communication Interface (SCI)/Local Interconnect Network (LIN) Module

---

---

---

This chapter describes the serial communication interface (SCI) / local interconnect network (LIN) module. The SCI/LIN is compliant to the LIN 2.1 protocol specified in the *LIN Specification Package*. This module can be configured to operate in either SCI (UART) or LIN mode.

---

**NOTE:** This chapter describes a superset implementation of the LIN/SCI module that includes features and functionality that require DMA. Since not all devices have DMA capability, consult your device-specific datasheet to determine applicability of these features and functions to your device being used.

---

## 29.1 Introduction and Features

The SCI/LIN module can be programmed to work either as an SCI or as a LIN. The core of the module is an SCI. The SCI's hardware features are augmented to achieve LIN compatibility.

The SCI module is a universal asynchronous receiver-transmitter that implements the standard nonreturn to zero format. The SCI can be used to communicate, for example, through an RS-232 port or over a K-line.

The LIN standard is based on the SCI (UART) serial data link format. The communication concept is single-master/multiple-slave with a message identification for multi-cast transmission between any network nodes.

Throughout the chapter Compatibility Mode refers to SCI Mode functionality of SCI/LIN Module. The initial part of the chapter explains about the SCI functionality and later part about the LIN functionality. Though the register are common for LIN and SCI, the register descriptions has notes to identify the register / bit usage in different modes.

### 29.1.1 SCI Features

The following are the features of the SCI module:

- Standard universal asynchronous receiver-transmitter (UART) communication
- Supports full- or half-duplex operation
- Standard nonreturn to zero (NRZ) format
- Double-buffered receive and transmit functions in compatibility mode
- Supports two individually enabled interrupt lines: level 0 and level 1
- Configurable frame format of 3 to 13 bits per character based on the following:
  - Data word length programmable from one to eight bits
  - Additional address bit in address-bit mode
  - Parity programmable for zero or one parity bit, odd or even parity
  - Stop programmable for one or two stop bits
- Asynchronous or isosynchronous communication modes
- Two multiprocessor communication formats allow communication between more than two devices
- Sleep mode is available to free CPU resources during multiprocessor communication and then wake up to receive an incoming message
- The 24-bit programmable baud rate supports  $2^{24}$  different baud rates provide high accuracy baud rate selection
- At 100MHz Peripheral Clock, 3.125 Mbits/s is the Max Baud Rate achievable
- Capability to use Direct Memory Access (DMA) for transmit and receive data
- Five error flags and Seven status flags provide detailed information regarding SCI events
- Two external pins: LINRX and LINTX
- Multi-buffered receive and transmit units

---

**NOTE:** SCI/LIN module does not support UART hardware flow control. This feature can be implemented in software using a general purpose I/O pin.

---

### 29.1.2 LIN Features

The following are the features of the LIN module:

- Compatibility with LIN 1.3, 2.0 and 2.1 protocols
- Configurable Baud Rate up to 20 Kbits/s
- Two external pins: LINRX and LINTX.
- Multi-buffered receive and transmit units
- Identification masks for message filtering
- Automatic master header generation
  - Programmable synchronization break field
  - Synchronization field
  - Identifier field
- Slave automatic synchronization
  - Synchronization break detection
  - Optional baud rate update
  - Synchronization validation
- $2^{31}$  programmable transmission rates with 7 fractional bits
- Wakeup on LINRX dominant level from transceiver
- Automatic wakeup support
  - Wakeup signal generation
  - Expiration times on wakeup signals
- Automatic bus idle detection
- Error detection
  - Bit error
  - Bus error
  - No-response error
  - Checksum error
  - Synchronization field error
  - Parity error
- Capability to use Direct Memory Access (DMA) for transmit and receive data.
- 2 Interrupt lines with priority encoding for:
  - Receive
  - Transmit
  - ID, error, and status
- Support for LIN 2.0 checksum
- Enhanced synchronizer finite state machine (FSM) support for frame processing
- Enhanced handling of extended frames
- Enhanced baud rate generator
- Update wakeup/go to sleep

### 29.1.3 Block Diagram

The SCI/LIN module contains core SCI block with added sub-blocks to support LIN protocol.

Three Major components of the SCI Module are:

- Transmitter
- Baud Clock Generator
- Receiver

**Transmitter (TX)** contains two major registers to perform the double- buffering:

- The transmitter data buffer register (SCITD) contains data loaded by the CPU to be transferred to the shift register for transmission.
- The transmitter shift register (SCITXSHF) loads data from the data buffer (SCITD) and shifts data onto the LINTX pin, one bit at a time.

#### Baud Clock Generator

- A programmable baud generator produces either a baud clock scaled from VBUSP CLK.

**Receiver (RX)** contains two major registers to perform the double- buffering:

- The receiver shift register (SCIRXSHF) shifts data in from the LINRX pin one bit at a time and transfers completed data into the receive data buffer.
- The receiver data buffer register (SCIRD) contains received data transferred from the receiver shift register

The SCI receiver and transmitter are double-buffered, and each has its own separate enable and interrupt bits. The receiver and transmitter may each be operated independently or simultaneously in full duplex mode.

To ensure data integrity, the SCI checks the data it receives for breaks, parity, overrun, and framing errors. The bit rate (baud) is programmable to over 16 million different rates through a 24-bit baud-select register. [Figure 29-1](#) shows the detailed SCI block diagram.

The SCI/LIN module is based on the standalone SCI with the addition of an error detector (parity calculator, checksum calculator, and bit monitor), a mask filter, a synchronizer, and a multibuffered receiver and transmitter. The SCI interface, the DMA control subblocks and the baud generator are modified as part of the hardware enhancements for LIN compatibility. [Figure 29-2](#) shows the SCI/LIN block diagram.

Figure 29-2. SCI/LIN Block Diagram

## 29.2 SCI Communication Formats

The SCI module can be configured to meet the requirements of many applications. Because communication formats vary depending on the specific application, many attributes of the SCI/LIN are user configurable. The list below describes these configuration options:

- SCI Frame format
- SCI Timing modes
- SCI Baud rate
- SCI Multiprocessor modes

### 29.2.1 SCI Frame Formats

The SCI uses a programmable frame format. All frames consist of the following:

- One start bit
- One to eight data bits
- Zero or one address bit
- Zero or one parity bit
- One or two stop bits

The frame format for both the transmitter and receiver is programmable through the bits in the SCIGCR1 register. Both receive and transmit data is in nonreturn to zero (NRZ) format, which means that the transmit and receive lines are at logic high when idle. Each frame transmission begins with a start bit, in which the transmitter pulls the SCI line low (logic low). Following the start bit, the frame data is sent and received least significant bit first (LSB).

An address bit is present in each frame if the SCI is configured to be in address-bit mode but is not present in any frame if the SCI is configured for idle-line mode. The format of frames with and without the address bit is illustrated in [Figure 29-3](#).

A parity bit is present in every frame when the PARITY ENA bit is set. The value of the parity bit depends on the number of one bits in the frame and whether odd or even parity has been selected via the PARITY ENA bit. Both examples in [Figure 29-3](#) have parity enabled.

All frames include one stop bit, which is always a high level. This high level at the end of each frame is used to indicate the end of a frame to ensure synchronization between communicating devices. Two stop bits are transmitted if the STOP bit in SCIGCR1 register is set. The examples shown in [Figure 29-3](#) use one stop bit per frame.

**Figure 29-3. Typical SCI Data Frame Formats**

## 29.2.2 SCI Timing Mode

The SCI can be configured to use asynchronous or isosynchronous timing using TIMING MODE bit in SCIGCR1 register.

### 29.2.2.1 Asynchronous Timing Mode

The asynchronous timing mode uses only the receive and transmit data lines to interface with devices using the standard universal asynchronous receiver-transmitter (UART) protocol.

In the asynchronous timing mode, each bit in a frame has a duration of 16 SCI baud clock periods. Each bit therefore consists of 16 samples (one for each clock period). When the SCI is using asynchronous mode, the baud rates of all communicating devices must match as closely as possible. Receive errors result from devices communicating at different baud rates.

With the receiver in the asynchronous timing mode, the SCI detects a valid start bit if the first four samples after a falling edge on the LINRX pin are of logic level 0. As soon as a falling edge is detected on LINRX, the SCI assumes that a frame is being received and synchronizes itself to the bus.

To prevent interpreting noise as Start bit SCI expects LINRX line to be low for at least four contiguous SCI baud clock periods to detect a valid start bit. The bus is considered idle if this condition is not met. When a valid start bit is detected, the SCI determines the value of each bit by sampling the LINRX line value during the seventh, eighth, and ninth SCI baud clock periods. A majority vote of these three samples is used to determine the value stored in the SCI receiver shift register. By sampling in the middle of the bit, the SCI reduces errors caused by propagation delays and rise and fall times and data line noises.

Figure 29-4 illustrates how the receiver samples a start bit and a data bit in asynchronous timing mode.

The transmitter transmits each bit for a duration of 16 SCI baud clock periods. During the first clock period for a bit, the transmitter shifts the value of that bit onto the LINTX pin. The transmitter then holds the current bit value on LINTX for 16 SCI baud clock periods.

**Figure 29-4. Asynchronous Communication Bit Timing**

### 29.2.2.2 Isosynchronous Timing Mode

In isosynchronous timing mode, each bit in a frame has a duration of exactly 1 baud clock period and therefore consists of a single sample. With this timing configuration, the transmitter and receiver are required to make use of the SCICLK pin to synchronize communication with other SCI. **This mode is not supported on this device because SCICLK pin is not available.**

## 29.2.3 SCI Baud Rate

The SCI/LIN has an internally generated serial clock determined by the peripheral VCLK and the prescalers P and M in this register. The SCI uses the 24-bit integer prescaler P value of BRSR register to select the required baud rates. The additional 4-bit fractional divider M refines the baudrate selection.

In asynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$SCICLK \text{ Frequency} = \frac{VCLK \text{ Frequency}}{P + 1 + \frac{M}{16}}$$

$$\text{Asynchronous baud value} = \frac{SCICLK \text{ Frequency}}{16}$$

For P = 0,

$$\text{Asynchronous baud value} = \frac{VCLK \text{ Frequency}}{32} \quad (45)$$

### 29.2.3.1 Superfractional Divider, SCI Asynchronous Mode

The superfractional divider is available in SCI asynchronous mode (idle-line and address-bit mode). Building on the 4-bit fractional divider M (BRSR[27:24]), the superfractional divider uses an additional 3-bit modulating value, illustrated in Table 29-2. The bits with a 1 in the table will have an additional VCLK period added to their  $T_{bit}$ . If the character length is more than 10, then the modulation table will be a rolled-over version of the original table (Table 29-1), as shown in Table 29-2.

The baud rate will vary over a data field to average according to the BRSR[30:28] value by a “d” fraction of the peripheral internal clock:  $0 < d < 1$ . Refer Figure 29-5 for a simple Average “d” calculation based on “U” value(BRSR[30:28]).

The instantaneous bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d (0 or 1),

$$T^{i}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK} \quad (46)$$

For P = 0  $T_{bit} = 32T_{VCLK}$

The averaged bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d ( $0 < d < 1$ ),

$$T^{a}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK} \quad (47)$$

For P = 0  $T_{bit} = 32T_{VCLK}$

**Table 29-1. Superfractional Bit Modulation for SCI Mode (Normal Configuration) <sup>(1)</sup>**

| BRS[30:28] | Start Bit | D[0] | D[1] | D[2] | D[3] | D[4] | D[5] | D[6] | D[7] | Stop Bit |
|------------|-----------|------|------|------|------|------|------|------|------|----------|
| 0          | 0         | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0        |
| 1          | 1         | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 1    | 0        |

## 29.2.4 SCI Multiprocessor Communication Modes

In some applications, the SCI may be connected to more than one serial communication device. In such a multiprocessor configuration, several frames of data may be sent to all connected devices or to an individual device. In the case of data sent to an individual device, the receiving devices must determine when they are being addressed. When a message is not intended for them, the devices can ignore the following data. When only two devices make up the SCI network, addressing is not needed, so multiprocessor communication schemes are not required.

SCI supports two multiprocessor communication modes which can be selected using COMM MODE bit:

- Idle-Line Mode
- Address Bit Mode

When the SCI is not used in a multiprocessor environment, software can consider all frames as data frames. In this case, the only distinction between the idle-line and address-bit modes is the presence of an extra bit (the address bit) in each frame sent with the address-bit protocol.

The SCI allows full-duplex communication where data can be sent and received via the transmit and receive pins simultaneously. However, the protocol used by the SCI assumes that only one device transmits data on the same bus line at any one time. No arbitration is done by the SCI.

### 29.2.4.1 Idle-Line Multiprocessor Modes

In idle-line multiprocessor mode, a frame that is preceded by an idle period (10 or more idle bits) is an address frame. A frame that is preceded by fewer than 10 idle bits is a data frame. [Figure 29-6](#) illustrates the format of several blocks and frames with idle-line mode.

There are two ways to transmit an address frame using idle-line mode:

**Method 1:** In software, deliberately leave an idle period between the transmission of the last data frame of the previous block and the address frame of the new block.

**Method 2:** Configure the SCI to automatically send an idle period between the last data frame of the previous block and the address frame of the new block.

Although Method 1 is only accomplished by a delay loop in software, Method 2 can be implemented by using the transmit buffer and the TXWAKE bit in the following manner:

Step 1: Write a 1 to the TXWAKE bit.

Step 2: Write a dummy data value to the SCITD register. This triggers the SCI to begin the idle period as soon as the transmitter shift register is empty.

Step 3: Wait for the SCI to clear the TXWAKE flag.

Step 4: Write the address value to SCITD.

As indicated by Step 3, software should wait for the SCI to clear the TXWAKE bit. However, the SCI clears the TXWAKE bit at the same time it sets TXRDY (that is, transfers data from SCITD into SCITXSHF). Therefore, if the TX INT ENA bit is set, the transfer of data from SCITD to SCITXSHF causes an interrupt to be generated at the same time that the SCI clears the TXWAKE bit. If this interrupt method is used, software is not required to poll the TXWAKE bit waiting for the SCI to clear it.

When idle-line multiprocessor communications are used, software must ensure that the idle time exceeds 10 bit periods before addresses (using one of the methods mentioned above), and software must also ensure that data frames are written to the transmitter quickly enough to be sent without a delay of 10 bit periods between frames. Failure to comply with these conditions will result in data interpretation errors by other devices receiving the transmission.

**Figure 29-6. Idle-Line Multiprocessor Communication Format**

#### 29.2.4.2 Address-Bit Multiprocessor Mode

In the address-bit protocol, each frame has an extra bit immediately following the data field called an address bit. A frame with the address bit set to 1 is an address frame; a frame with the address bit set to 0 is a data frame. The idle period timing is irrelevant in this mode. [Figure 29-7](#) illustrates the format of several blocks and frames with the address-bit mode.

When address-bit mode is used, the value of the TXWAKE bit is the value sent as the address bit. To send an address frame, software must set the TXWAKE bit. This bit is cleared as the contents of the SCITD are shifted from the TXWAKE register so that all frames sent are data except when the TXWAKE bit is written as a 1.

No dummy write to SCITD is required before an address frame is sent in address-bit mode. The first byte written to SCITD after the TXWAKE bit is written to 1 is transmitted with the address bit set when address-bit mode is used.

**Figure 29-7. Address-Bit Multiprocessor Communication Format**

Figure 29-9. Transmit Buffers

## 29.3 SCI Interrupts

The SCI/LIN module has two interrupt lines, level 0 and level 1, to the vectored interrupt manager (VIM) module (see [Figure 29-10](#)). Two offset registers SCIINTVECT0 and SCIINTVECT1 determine which flag triggered the interrupt according to the respective priority encoders. Each interrupt condition has a bit to enable/disable the interrupt in the SCISSETINT and SCICLRINT registers respectively.

Each interrupt also has a bit that can be set as interrupt level 0 (INT0) or as interrupt level 1 (INT1). By default, interrupts are in interrupt level 0. SCISSETINTLVL sets a given interrupt to level 1. SCICLEARINTLVL resets a given interrupt level to the default level 0.

The interrupt vector registers SCIINTVECT0 and SCIINTVECT1 return the vector of the pending interrupt line INT0 or INT1. If more than one interrupt is pending, the interrupt vector register holds the highest priority interrupt.

**Figure 29-10. General Interrupt Scheme**

**Figure 29-11. Interrupt Generation for Given Flags**

### 29.3.1 Transmit Interrupt

To use transmit interrupt functionality, SET TX INT bit must be enabled and SET TX DMA bit must be cleared. The transmit ready (TXRDY) flag is set when the SCI transfers the contents of SCITD to the shift register, SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty. If the SET TX INT bit is set, then a transmit interrupt is generated when the TXRDY flag goes high. Transmit Interrupt is not generated immediately after setting the SET TX INT bit unlike transmit DMA request. Transmit Interrupt is generated only after the first transfer from SCITD to SCITXSHF, that is first data has to be written to SCITD by the User before any interrupt gets generated. To transmit further data the user can write data to SCITD in the transmit Interrupt service routine.

Writing data to the SCITD register clears the TXRDY bit. When this data has been moved to the SCITXSHF register, the TXRDY bit is set again. The interrupt request can be suspended by setting the CLR TX INT bit; however, when the SET TX INT bit is again set to 1, the TXRDY interrupt is asserted again. The transmit interrupt request can be eliminated until the next series of values is written to SCITD, by disabling the transmitter via the TXENA bit, by a software reset SWnRST, or by a device hardware reset.

### 29.3.2 Receive Interrupt

The receive ready (RXRDY) flag is set when the SCI transfers newly received data from SCIRXSHF to SCIRD. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive interrupts are enabled by the SET RX INT bit. If the SET RX INT is set when the SCI sets the RXRDY flag, then a receive interrupt is generated. The received data can be read in the Interrupt Service routine.

On a device with both SCI and a DMA controller, the bits SET RX DMA ALL and SET RX DMA must be cleared to select interrupt functionality.

### 29.3.3 WakeUp Interrupt

SCI sets the WAKEUP flag if bus activity on the RX line either prevents power-down mode from being entered, or RX line activity causes an exit from power-down mode. If enabled (SET WAKEUP INT), wakeup interrupt is triggered once WAKEUP flag is set.

### 29.3.4 Error Interrupts

The following error detection are supported with Interrupt by the SCI module:

- Parity errors (PE)
- Frame errors (FE)
- Break Detect errors (BRKDT)
- Overrun errors (OE)
- Bit errors (BE)

If all of these errors (PE, FE, BRKDT, OE, BE) are flagged, an interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame. Each of these flags is located in the receiver status (SCIFLR) register.

There are 16 interrupt sources in the SCI/LIN module, In SCI mode 8 interrupts are supported, as seen in [Table 29-4](#).

**Table 29-4. SCI/LIN Interrupts**

| Offset <sup>(1)</sup> | Interrupt                                  | Applicable to SCI | Applicable to LIN |
|-----------------------|--------------------------------------------|-------------------|-------------------|
| 0                     | No interrupt                               |                   |                   |
| 1                     | Wakeup                                     | Yes               | Yes               |
| 2                     | Inconsistent-synch-field error             | No                | Yes               |
| 3                     | Parity error                               | Yes               | Yes               |
| 4                     | ID                                         | No                | Yes               |
| 5                     | Physical bus error                         | No                | Yes               |
| 6                     | Frame error                                | Yes               | Yes               |
| 7                     | Break detect                               | Yes               | No                |
| 8                     | Checksum error                             | No                | Yes               |
| 9                     | Overrun error                              | Yes               | Yes               |
| 10                    | Bit error                                  | Yes               | Yes               |
| 11                    | Receive                                    | Yes               | Yes               |
| 12                    | Transmit                                   | Yes               | Yes               |
| 13                    | No-response error                          | No                | Yes               |
| 14                    | Timeout after wakeup signal (150 ms)       | No                | Yes               |
| 15                    | Timeout after three wakeup signals (1.5 s) | No                | Yes               |
| 16                    | Timeout (Bus Idle, 4s)                     | No                | Yes               |

<sup>(1)</sup> Offset 1 is the highest priority. Offset 16 is the lowest priority.

## 29.4 SCI DMA Interface

DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. The DMA transfers depending on whether multibuffer mode bit ( MBUF MODE) is enabled or not. For DMA module configuration refer

### 29.4.1 Receive DMA Requests

This DMA functionality is enabled/disabled by the CPU using the SET RX DMA/CLR RX DMA bits, respectively.

In Multi Buffered SCI mode with DMA enabled, the receiver loads the RDy buffers for each received character. RX DMA request is triggered once the last character of the programmed number of characters (LENGTH) are received and copied to the corresponding RDy buffer successfully.

If the multibuffer option is disabled, then DMA requests will be generated on a byte-per-byte basis until all the expected response data fields are received.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames or DMA requests for both. This is controlled by the SET RX DMA ALL bit.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received.

### 29.4.2 Transmit DMA Requests

DMA functionality is enabled/disabled by the CPU with SET TX DMA/CLR TX DMA bits, respectively.

In Multi Buffered SCI mode once TXRDY bit is set or after a transmission of programmed no.of characters (LENGTH) (up to eight data bytes stored in the transmit buffer(s) TDy in the LINTD0 and LINTD1 registers), a DMA request is generated in order to reload the transmit buffer for the next transmission. If the multibuffer option is disabled, then DMA requests will be generated on a byte-per-byte basis until all bytes are transferred.

## 29.5 SCI Configurations

Before the SCI sends or receives data, its registers should be properly configured. Upon power-up or a system-level reset, each bit in the SCI registers is set to a default state. The registers are writable only after the RESET bit is set to 1. Of particular importance is the SWnRST bit. This active-low bit is initialized to 0 and keeps the SCI in a reset state until it is programmed to 1. Therefore, all SCI configuration should be completed before a 1 (one) is written to the SWnRST bit.

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as SWnRST is held low the entire time that the SCI is being configured, the order in which the registers are programmed is not important.

- Enable SCI by setting RESET bit.
- Clear SWnRST to 0 before configuring the SCI.
- Select the desired frame format by programming SCIGCR1.
- Configure the LINRX and LINTX pins for SCI functionality by setting the RX FUNC and TX FUNC bit.
- Select the baud rate to be used for communication by programming BRSR.
- Select internal clock by programming the CLOCK bit.
- Set the CONT bit to make SCI not to halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set LOOP BACK bit to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Select the receiver enable RXENA bit if data is to be received.
- Select the transmit enable TXENA bit if data is to be transmitted.
- Set SWnRST to 1 after the SCI is configured.
- Perform Receive or Transmit data..

### 29.5.1 Receiving Data

The SCI receiver is enabled to receive messages if the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the LINRX pin functions as a general purpose I/O pin rather than as an SCI function pin.

SCI module can receive data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multi-Buffer Mode

After a valid idle period is detected, data is automatically received as it arrives on the LINRX pin.

#### 29.5.1.1 Receiving Data in Single-Buffer Mode

Single Buffer Mode is selected when MBUF MODE bit is 0. In this mode SCI sets the RXRDY bit when it transfers newly received data from SCIRXSHF to SCIRD. The SCI clears the RXRDY bit after the new data in SCIRD has been read. Also, as data is transferred from SCIRXSHF to SCIRD, the SCI sets FE, OE, or PE if any of these error conditions were detected in the received data. These error conditions are supported with configurable Interrupt capability. The wake-up and break-detect status bits are also set if one of these errors occurs, but they do not necessarily occur at the same time that new data is being loaded into SCIRD.

User can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for RXRDY bit and read the data from SCIRD register once RXRDY is set high. CPU is unnecessarily overloaded by selecting Polling mode. To avoid this user can use either Interrupt or DMA method. To use interrupt method SET RX INT bit should be set and to use DMA SET RX DMA bit should be set. Either an Interrupt or a DMA request is generated the moment RXRDY is set.

### 29.5.1.2 Receiving Data in Multi-Buffer Mode

Multi-Buffer Mode is selected when MBUF MODE bit is 1. In this mode SCI sets the RXRDY bit when programmed number of data are received in the receive buffer, the complete frame. The error condition detection logic is same as Single Buffer Mode, except that it monitors for the complete frame. Like Single Buffer Mode the user can use either Interrupt, DMA or polling method to read the data. The received data has to be read from the LINRD0 and LINRD1 register, based on the number of bytes. For LENGTH less than or equal to 4, Read to LINRD0 register will clear the “RXRDY” flag. For LENGTH greater than 4, Read to LINRD1 register will clear the “RXRDY” flag.

## 29.5.2 Transmitting Data

The SCI transmitter is enabled if the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the LINTX pin functions as a general purpose I/O pin rather than as an SCI function pin. Any value written to the SCITD before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

SCI module can transmit data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multi-Buffered or Buffered SCI Mode.

### 29.5.2.1 Transmitting Data in Single-Buffer Mode

Single Buffer Mode is selected when MBUF MODE bit is 0. In this mode SCI waits for data to be written to SCITD, transfers it to SCITXSHF, and transmits it. The flags TXRDY and TX EMPTY indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to SCITD, the TXRDY bit is set. Additionally, if both SCITD and SCITXSHF are empty, then the TX EMPTY bit is also set.

User can transmit data by:

1. Polling Transmit Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for TXRDY bit to go high before writing the data to SCITD register. CPU is unnecessarily overloaded by doing this Polling method. To avoid this user can use either Interrupt or DMA method. To use interrupt method SET TX INT bit should be set and to use DMA SET TX DMA bit should be set. Either an Interrupt or a DMA request is generated the moment TXRDY is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and SCITD are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can be done by either disabling the transmit interrupt (CLR TX INT) / DMA request (CLR TX DMA bit) or by disabling the transmitter (clear TXENA bit).

---

**NOTE:** The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

---

### 29.5.2.2 Transmitting Data in Multi-Buffer Mode

Multi-Buffer Mode is selected when MBUF MODE bit is 1. Similar to Single Buffer Mode the software can use polling, Interrupt or DMA method to write the data to be transmitted. The data to be transmitted has to be written to LINTD0 and LINTD1 register, based on the number of bytes. SCI waits for data to be written to Byte 0(TD0) of LINTD0 register and transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically.

## 29.6 SCI Low Power Mode

The SCI/LIN can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and the module registers. Setting the POWERDOWN bit causes the SCI to enter local low-power mode and clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SCI for that particular access alone.

The wake-up interrupt is used to allow the SCI to exit low-power mode automatically when a low level is detected on the LINRX pin and also this clears the POWERDOWN bit. If wake-up interrupt is disabled, then the SCI/LIN immediately enters low-power mode whenever it is requested and also any activity on the LINRX pin does not cause the SCI to exit low-power mode.

---

**NOTE: Enabling Local Low-Power Mode During Receive and Transmit**

If the wake-up interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI immediately generates a wake-up interrupt to clear the powerdown bit and prevents the SCI from entering low-power mode and thus completes the current reception. Otherwise, if the wake-up interrupt is disabled, then the SCI completes the current reception and then enters the low-power mode.

---

### 29.6.1 Sleep Mode for Multiprocessor Communication

When the SCI receives data and transfers that data from SCIRXSHF to SCIRD, the RXRDY bit is set and if RX INT ENA is set, the SCI also generates an interrupt. The interrupt triggers the CPU to read the newly received frame before another one is received. In multiprocessor communication modes, this default behavior may be enhanced to provide selective indication of new data. When SCI receives an address frame that does not match its address, the device can ignore the data following this non-matching address until the next address frame by using sleep mode. Sleep mode can be used with both idle-line and address-bit multiprocessor modes.

If sleep mode is enabled by the SLEEP bit, then the SCI transfers data from SCIRXSHF to SCIRD only for address frames. Therefore, in sleep mode, all data frames are assembled in the SCIRXSHF register without being shifted into the SCIRD and without initiating a receive interrupt or DMA request. Upon reception of an address frame, the contents of the SCIRXSHF are moved into SCIRD, and the software must read SCIRD and determine if the SCI is being addressed by comparing the received address against the address previously set in the software and stored somewhere in memory (the SCI does not have hardware available for address comparison). If the SCI is being addressed, the software must clear the SLEEP bit so that the SCI will load SCIRD with the data of the data frames that follow the address frame.

When the SCI has been addressed and sleep mode has been disabled (in software) to allow the receipt of data, the SCI should check the RXWAKE bit (SCIFLR.12) to determine when the next address has been received. This bit is set to 1 if the current value in SCIRD is an address and set to 0 if SCIRD contains data. If the RXWAKE bit is set, then software should check the address in SCIRD against its own address. If it is still being addressed, then sleep mode should remain disabled. Otherwise, the SLEEP bit should be set again.

Following is a sequence of events typical of sleep mode operation:

- The SCI is configured and both sleep mode and receive actions are enabled.
- An address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is not being addressed, so the value of the SLEEP bit is not changed.
- Several data frames are shifted into SCIRXSHF, but no data is moved to SCIRD and no receive interrupts are generated.
- A new address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is being addressed and clears the SLEEP bit.
- Data shifted into SCIRXSHF is transferred to SCIRD, and a receive interrupt is generated after each data frame is received.
- In each interrupt routine, software checks RXWAKE to determine if the current frame is an address frame.
- Another address frame is received, RXWAKE is set, software determines that the SCI is not being addressed and sets the SLEEP bit back to 1. No receive interrupts are generated for the data frames following this address frame.

By ignoring data frames that are not intended for the device, fewer interrupts are generated. These interrupts would otherwise require CPU intervention to read data that is of no significance to this specific device. Using sleep mode can help free some CPU resources.

Except for the RXRDY flag, the SCI continues to update the receiver status flags (see [Table 29-12](#)) while sleep mode is active. In this way, if an error occurs on the receive line, an application can immediately respond to the error and take the appropriate corrective action.

Because the RXRDY bit is not updated for data frames when sleep mode is enabled, the SCI can enable sleep mode and use a polling algorithm if desired. In this case, when RXRDY is set, software knows that a new address has been received. If the SCI is not being addressed, then the software should not change the value of the SLEEP bit and should continue to poll RXRDY.

## 29.7 LIN Communication Formats

The SCI/LIN module can be used in LIN mode or SCI mode. The enhancements for baud generation, DMA controls and additional receive/transmit buffers necessary for LIN mode operation are also part of the enhanced buffered SCI module. LIN mode is selected by enabling LIN MODE bit in SCIGCR1 register.

---

**NOTE:** The SCI/LIN is built around the SCI platform and uses a similar sampling scheme: 16 samples for each bit with majority vote on samples 8, 9, and 10.

---

The SCI/LIN control registers are located at the SCI/LIN base address. For a detailed description of each register, see [Section 29.13](#).

### 29.7.1 LIN Standards

For compatibility with LIN2.0 standard the following additional features are implemented over LIN1.3:

- (i) Support for LIN 2.0 checksum
- (ii) Enhanced synchronizer FSM support for frame processing
- (iii) Enhanced handling of extended frames
- (iv) Enhanced baudrate generator
- (v) Update wakeup/go to sleep

The LIN module covers the CPU performance-consuming features, defined in the *LIN Specification Package* Revision 1.3 and 2.0 by hardware.

The Master Mode of LIN module is compatible with LIN 2.1 standard.

## 29.7.2 Message Frame

The LIN protocol defines a message frame format, illustrated in Figure 29-12. Each frame includes one master header, one response, one in-frame response space, and inter-byte spaces. In-frame-response and inter-byte spaces may be 0.

There is no arbitration in the definition of the LIN protocol; therefore, multiple slave nodes responding to a header might be detected as an error.

The LIN bus is a single channel wired-AND. The bus has a binary level: either dominant for a value of 0, or recessive for a value of 1.

**Figure 29-12. LIN Protocol Message Frame Format: Master Header and Slave Response**

### 29.7.2.1 Message Header

The header of a message is initiated by a master (see Figure 29-13) and consists of a three field-sequence:

- The synch break field signaling the beginning of a message
- The synch field conveying bit rate information of the LIN bus
- The ID field denoting the content of a message

**Figure 29-13. Header 3 Fields: Synch Break, Synch, and ID**

### 29.7.2.2 Response

The format of the response is as illustrated in [Figure 29-14](#). There are two types of fields in a response: data and checksum. The data field consists of exactly one data byte, one start bit, and one stop bit, for a total of 10 bits. The LSB is transmitted first. The checksum field consists of one checksum byte, one start bit and one stop bit. The checksum byte is the inverted modulo-256 sum over all data bytes in the data fields of the response.

**Figure 29-14. Response Format of LIN Message Frame**

The format of the response is a stream of N data fields and one checksum field. Typically N is from 1 to 8, with the exception of the extended command frames ([Section 29.7.6](#)). The length N of the response is indicated either with the optional length control bits of the ID Field (this is used in standards earlier than LIN 1.x); see [Table 29-5](#), or by LENGTH value in SCIFORMAT[18:16] register; see [Table 29-6](#). The SCI/LIN module supports response lengths from 1 to 8 bytes in compliance with LIN 2.0.

**Table 29-5. Response Length Info Using IDBYTE Field Bits [5:4] for LIN Standards Earlier than 1.3**

| ID5 | ID4 | Number of Data bytes |
|-----|-----|----------------------|
| 0   | 0   | 2                    |
| 0   | 1   | 2                    |
| 1   | 0   | 4                    |
| 1   | 1   | 8                    |

**Table 29-6. Response Length with SCIFORMAT[18:16] Programming**

| SCIFORMAT[18:16] | No. of Bytes |
|------------------|--------------|
| 000              | 1            |
| 001              | 2            |
| 010              | 3            |
| 011              | 4            |
| 100              | 5            |
| 101              | 6            |
| 110              | 7            |
| 111              | 8            |

### 29.7.3 Synchronizer

The synchronizer has three major functions in the messaging between master and slave nodes. It generates the master header data stream, it synchronizes to the LIN bus for responding, and it locally detects timeouts. A bit rate is programmed using the prescalers in the BRSR register to match the indicated LIN\_speed value in the LIN description file.

The LIN synchronizer will perform the following functions: master header signal generation, slave detection and synchronization to message header with optional baud rate adjustment, response transmission timing and timeout control.

The LIN synchronizer is capable of detecting an incoming break and initializing communication at all times.

### 29.7.4 Baud Rate

The transmission baud rate of any node is configured by the CPU at the beginning; this defines the bit time  $T_{bit}$ . The bit time is derived from the fields P and M in the baud rate selection register (BRSR). There is an additional 3-bit fractional divider value, field U in the BRSR, which further fine-tunes the data field baud rate.

The ranges for the prescaler values in the BRSR register are:

$$P = 0, 1, 2, 3, \dots, 2^{24} - 1$$

$$M = 0, 1, 2, \dots, 15$$

$$U = 0, 1, 2, 3, 4, 5, 6, 7$$

The P, M, and U values in the BRSR register are user programmable. The P and M dividers could be used for both SCI mode and LIN mode to select a baud rate. The U value is an additional 3-bit value determining that "a TVCLK" (with a = 0,1) is added to each  $T_{bit}$  as explained in [Section 29.7.4.2](#). If the ADAPT bit is set and the LIN slave is in adaptive baud rate mode, then all these divider values are automatically obtained during header reception when the synchronization field is measured.

The LIN protocol defines baud rate boundaries as follows:

$$1\text{kHz} \leq F_{LINCLK} \leq 20\text{kHz}$$

All transmitted bits are shifted in and out at  $T_{bit}$  periods.

#### 29.7.4.1 Fractional Divider

The M field of the BRSR register modifies the integer prescaler P for finer tuning of the baud rate. The M value adds in increments of 1/16 of the P value.

The bit time,  $T_{bit}$  is expressed in terms of the VCLK period  $T_{VCLK}$  as follows:

For all P other than 0, and all M,

$$T_{bit} = 16 \left( P + 1 + \frac{M}{16} \right) T_{VCLK} \quad (48)$$

For P = 0 :  $T_{bit} = 32T_{VCLK}$

Therefore, the LINCLK frequency is given by:

$$F_{LINCLK} = \frac{F_{VCLK}}{16(P + 1 + \frac{M}{16})} \quad \text{For all } P \text{ other than zero}$$

$$F_{LINCLK} = \frac{F_{VCLK}}{32} \quad \text{For } P = 0 \quad (49)$$

### 29.7.4.2 Superfractional Divider

The superfractional divider scheme applies to the following modes:

- LIN master mode (synch field + identifier field + response field + checksum field)
- LIN slave mode (response field + checksum field)

### 29.7.4.3 Superfractional Divider In LIN Mode

Building on the 4-bit fractional divider M (BRSR[27:24], the superfractional divider uses an additional 3-bit modulating value, illustrated in Table 29-7. The sync field (0x55), the identifier field and the response field can all be seen as 8-bit data bytes flanked by a start bit and a stop bit. The bits with a 1 in the table will have an additional VCLK period added to their  $T_{bit}$ .

**Table 29-7. Superfractional Bit Modulation for LIN Master Mode and Slave Mode <sup>(1)</sup>**

| BRS[30:28] | Start Bit | D[0] | D[1] | D[2] | D[3] | D[4] | D[5] | D[6] | D[7] | Stop Bit |
|------------|-----------|------|------|------|------|------|------|------|------|----------|
| 0          | 0         | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0        |
| 1          | 1         | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 1    | 0        |
| 2          | 1         | 0    | 0    | 0    | 1    | 0    | 0    | 0    | 1    | 0        |
| 3          | 1         | 0    | 1    | 0    | 1    | 0    | 0    | 0    | 1    | 0        |
| 4          | 1         | 0    | 1    | 0    | 1    | 0    | 1    | 0    | 1    | 0        |
| 5          | 1         | 1    | 1    | 0    | 1    | 0    | 1    | 0    | 1    | 1        |
| 6          | 1         | 1    | 1    | 0    | 1    | 1    | 1    | 0    | 1    | 1        |
| 7          | 1         | 1    | 1    | 1    | 1    | 1    | 1    | 0    | 1    | 1        |

(1)

1. In LIN master mode bit modulation applies to synch field + identifier field + response field
2. In LIN slave mode bit modulation applies to identifier field + response field

The baud rate will vary over a LIN data field to average according to the BRSR[30:28] value by a  $d$  fraction of the peripheral internal clock:  $0 < d < 1$ .

The instantaneous bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d (0 or 1),

$$T^{i}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK} \quad (50)$$

For P = 0  $T_{bit} = 32T_{VCLK}$

The averaged bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d ( $0 < d < 1$ ),

$$T^{a}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK} \quad (51)$$

For P = 0  $T_{bit} = 32T_{VCLK}$

With the superfractional divider, a LIN baud rate of 20 kbps is achievable with an internal clock VCLK of 726 kHz. Furthermore, a rate of 400 kbps is achievable with an VCLK of 14.6 MHz.

### 29.7.5 Header Generation

Automatic generation of the LIN protocol header data stream is supported without CPU interaction. The CPU or the DMA will trigger a message header generation and the LIN state machine will handle the generation itself. A master node initiates header generation on CPU or DMA writes to the IDBYTE in the LINID register. The header is always sent by the master to initiate a LIN communication and consists of three fields: break field, synchronization field, and identification field, as seen in Figure 29-15.

Figure 29-15. Message Header in Terms of  $T_{bit}$

- The break field consists of two components:
  - The synchronization break (SYNCH BREAK) consists of a minimum of 13 (dominant) low bits to a maximum of 20 dominant bits. The synch break length may be extended from the minimum with the 3-bit SBREAK value in the LINCOMP register.
  - The synchronization break delimiter (SDEL) consists of a minimum of 1 (recessive) high bit to a maximum of 4 recessive bits. The delimiter marks the end of the synchronization break field. The synch break delimiter length depends on the 2-bit SDEL value in the LINCOMP register.
- The synchronization field (SYNCH FIELD) consists of one start bit, byte 0x55, and a stop bit. It is used to convey  $T_{bit}$  information and resynchronize LIN bus nodes.
- The identifier field's ID byte may use six bits as an identifier, with optional length control (see *Note: Optional Control Length Bits*), and two optional bits as parity of the identifier. The identifier parity is used and checked if the PARITY ENA bit is set. If length control bits are not used, then there can be a total of 64 identifiers plus parity. If neither length control or parity are used there can be up to 256 identifiers. See Figure 29-16 for an illustration of the ID field.

Figure 29-16. ID Field

**NOTE: Optional Control Length Bits**

The control length bits only apply to LIN standards prior to LIN 1.3. IDBYTE field conveys response length information if compliant to standards earlier than LIN1.3. The SCIFORMAT register stores the length of the response for later versions of the LIN protocol.

**NOTE:** If the BLIN module, configured as Slave in multibuffer mode, is in the process of transmitting data while a new header comes in, the module might end up in responding with the data from the previous interrupted response (not the data corresponding to the new ID). To avoid this scenario the following procedure could be used:

1. Check for the Bit Error (BE) during the response transmission. If the BE flag is set, this indicates that a collision has happened on the LIN bus (here because of the new Synch Break).
2. In the Bit Error ISR, configure the TD0 and TD1 registers with the next set of data to be transmitted on a TX Match for the incoming ID. Before writing to TD0/TD1 make sure that there was not already an update because of a Bit Error; otherwise TD0/TD1 might be written twice for one ID.
3. Once the complete ID is received, based on the match, the newly configured data will be transmitted by the node.

### 29.7.5.1 Event Triggered Frame Handling Proposal

The LIN 2.0 protocol uses event-triggered frames that may occasionally cause collisions. Event-triggered frames have to be handled in software.

If no slave answers to an event triggered frame header, the master node will set the NRE flag, and a NRE interrupt will occur if enabled. If a collision occurs, a frame error and checksum error may arise before the NRE error. Those errors are flagged and the appropriate interrupts will occur, if enabled.

Frame errors and checksum errors depend on the behavior and synchronization of the responding slaves. If the slaves are totally synchronized and stop transmission once the collision occurred, it is possible that only the NRE error is flagged despite the occurrence of a collision. To detect if there has been a reception of one byte before the NRE error is flagged, the BUS BUSY flag can be used as an indicator.

The bus busy flag is set on the reception of the first bit of the header and remains set until the header reception is complete, and again is set on the reception of the first bit of the response. In the case of a collision the flag is cleared in the same cycle as the NRE flag is set.

Software could implement the following sequence:

- Once the reception of the header is done (poll for RXID flag), wait for the bus busy flag to get set or NRE flag to get set.
- If bus busy flag is not set before NRE flag, then it is a true no response case (no data has been transmitted onto the bus).
- If bus busy flag gets set, then wait for NRE flag to get set or for successful reception. If NRE flag is set, then in this case a collision has occurred on the bus.

Even in the case of a collision, the received (corrupted) data is accessible in the RX buffers; registers LINRD0 and LINRD1.

### 29.7.5.2 Header Reception and Adaptive Baud Rate

A slave node baud rate can optionally be adjusted to the detected bit rate as an option to the LIN module. The adaptive baud rate option is enabled by setting the ADAPT bit. During header reception, a slave measures the baud rate during detection of the synch field. If ADAPT bit is set, then the measured baud rate is compared to the slave node's programmed baud rate and adjusted to the LIN bus baud rate if necessary.

The LIN synchronizer determines two measurements: BRK\_count and BAUD\_count (Figure 29-17). These values are always calculated during the Header reception for synch field validation (Figure 29-18).

**Figure 29-17. Measurements for Synchronization**

By measuring the values BRK\_count and BAUD\_count, a valid synch break sequence can be detected as described in Figure 29-18. The four numbered events in Figure 29-17 signal the start/stop of the synchronizer counter. The synchronizer counter uses VCLK as the time base.

The synchronizer counter is used to measure the synch break relative to the detecting node  $T_{bit}$ . For a slave node receiving the synch break, a threshold of  $11 T_{bit}$  is used as required by the LIN protocol. For detection of the dominant data stream of the synch break, the synchronizer counter is started on a falling edge and stopped on a rising edge of the LINRX. On detection of the synch break delimiter, the synchronizer counter value is saved and then reset.

On detection of five consecutive falling edges, the BAUD\_count is measured. Bit timing calculation and consistency to required accuracy is implemented following the recommendations of LIN revision 2.0. A slave node can calculate a single  $T_{bit}$  time by division of BAUD\_count by 8. In addition, for consistency between the detected edges the following is evaluated:

$$BAUD\_count + BAUD\_count \gg 2 + BAUD\_count \gg 3 \leq BRK\_count$$

The BAUD\_count value is shifted 3 times to the right and rounded using the first insignificant bit to obtain a  $T_{bit}$  unit. If the ADAPT bit is set, then the detected baud rate is compared to the programmed baud rate.

During the header reception processing as illustrated in Figure 29-18, if the measured BRK\_count value is less than  $11 T_{bit}$ , the synch break is not valid according to the protocol for a fixed rate. If the ADAPT bit is set, then the MBRS is used for measuring BRK\_count and BAUD\_count values and automatically adjusts to any allowed LIN bus rate (refer to *LIN Specification Package 2.0*).

**NOTE:** In adaptive mode the MBRS divider should be set to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise a 0x00 data byte could mistakenly be detected as a synch break.

The break-threshold relative to the slave node is  $11 T_{bit}$ . The break is  $13 T_{bit}$  as specified in LIN version 1.3.

**Figure 29-18. Synchronization Validation Process and Baud Rate Adjustment**

If the synch field is not detected within the given tolerances, the inconsistent-synch-field-error (ISFE) flag will be set. An ISFE interrupt will be generated, if enabled by its respective bit in the SCISSETINT register. The ID byte should be received after the synch field validation was successful. Any time a valid break (larger than  $11 T_{bit}$ ) is detected, the receiver's state machine should reset to reception of this new frame. This reset condition is only valid during response state, not if an additional synch break occurs during header reception.

---

**NOTE:** When an inconsistent synch field (ISFE) error occurs, suggested action for the application is to Reset the SWnRST bit and Set the SWnRST bit to make sure that the internal state machines are back to their normal states

---

### 29.7.6 Extended Frames Handling

The LIN protocol 2.0 and prior includes two extended frames with identifiers 62 (user defined) and 63 (reserved extended). The response data length of the user-defined frame (ID 62, or 0x3E) is unlimited. The length for this identifier will be set at network configuration time to be shared with the LIN bus nodes.

Extended frame communication is triggered on reception of a header with identifier 0x3E; see [Figure 29-19](#). Once the extended frame communication is triggered, unlike normal frames, this communication needs to be stopped before issuing another header. To stop the extended frame communication the STOP EXT FRAME bit must be set.

**Figure 29-19. Optional Embedded Checksum in Response for Extended Frames**

An ID interrupt will be generated (if enabled and there is a match) on reception of ID 62 (0x3E). This interrupt allows the CPU using a software counter to keep track of the bytes that are being sent out and decides when to calculate and insert a checksum byte (recommended at periodic rates). To handle this procedure, SC bit is used. A write to the send checksum bit SC will initiate an automatic send of the checksum byte. The last data field should always be a checksum in compliance with the LIN protocol.

The periodicity of the checksum insertion, defined at network configuration time, is used by the receiving node to evaluate the checksum of the ongoing message, and has the benefit of enhanced reliability.

For the sending node, the checksum is automatically embedded each time the send checksum bit SC is set. For the receiving node, the checksum is compared each time the compare checksum bit CC is set; see [Figure 29-20](#).

---

**NOTE:** The LIN 2.0 enhanced checksum does not apply to the reserved identifiers. The reserved identifiers always use the classic checksum.

---

**Figure 29-20. Checksum Compare and Send for Extended Frames**

### 29.7.7 Timeout Control

Any LIN node listening to the bus and expecting a response initiated from a master node could flag a no-response error timeout event. The LIN protocol defines four types of timeout events, which are all handled by the hardware of the LIN module. The four LIN protocol events are:

- No-response timeout error
- Bus idle detection
- Timeout after wakeup signal
- Timeout after three wakeup signals

#### 29.7.7.1 No-Response Error (NRE)

The no-response error will occur when any node expecting a response waits for  $T_{\text{FRAME\_MAX}}$  time and the message frame is not fully completed within the maximum length allowed,  $T_{\text{FRAME\_MAX}}$ . After this time a no-response error (NRE) is flagged in the NRE bit of the SCIFLR register. An interrupt is triggered if enabled.

As specified in the LIN 1.3 standard, the minimum time to transmit a frame is:

$$T_{\text{FRAME\_MIN}} = T_{\text{HEADER\_MIN}} + T_{\text{DATA\_FIELD}} + T_{\text{CHECKSUM\_FIELD}}$$

$$= 44 + 10N$$

where  $N$  = number of data fields.

And the maximum time frame is given by:

$$T_{\text{FRAME\_MAX}} = T_{\text{FRAME\_MIN}} * 1.4$$

$$= (44 + 10N) * 1.4$$

The timeout value  $T_{\text{FRAME\_MAX}}$  is derived from the  $N$  number of data fields value. The  $N$  value is either embedded in the header's ID field for messages or is part of the description file. In the latter case, the 3-bit CHAR value in SCIFORMAT register, will indicate the value for  $N$ .

**NOTE:** The length coding of the ID field does not apply to two extended frame identifiers, ID fields of 0x3E (62) and 0x3F (63). In these cases, the ID field can be followed by an arbitrary number of data byte fields. Also, the LIN 2.0 protocol specification mentions that ID field 0x3F (63) cannot be used. For these two cases, the NRE will not be handled by the LIN controller hardware.

**Table 29-8. Timeout Values in  $T_{bit}$  Units**

| N | $T_{DATA\_FIELD}$ | $T_{FRAME\_MIN}$ | $T_{FRAME\_MAX}$ |
|---|-------------------|------------------|------------------|
| 1 | 10                | 54               | 76               |
| 2 | 20                | 64               | 90               |
| 3 | 30                | 74               | 104              |
| 4 | 40                | 84               | 118              |
| 5 | 50                | 94               | 132              |
| 6 | 60                | 104              | 146              |
| 7 | 70                | 114              | 160              |
| 8 | 80                | 124              | 174              |

### 29.7.7.2 Bus Idle Detection

The second type of timeout can occur when a node detects an inactive LIN bus: no transitions between recessive and dominant values are detected on the bus. This happens after a minimum of 4 s (this is 80,000  $F_{LINCLK}$  cycles with the fastest bus rate of 20 kbps). If a node detects no activity in the bus as the TIMEOUT bit is set, then it can be assumed that the LIN bus is in sleep mode. Application software can use the Timeout flag to determine when the LIN bus is inactive and put the LIN into sleep mode by writing the POWERDOWN bit.

---

**NOTE:** After the timeout was flagged, a SW nRESET should be asserted before entering Low Power Mode. This is required to reset the receiver in case that an incomplete frame was on the bus before the idle period.

---

### 29.7.7.3 Timeout after Wakeup Signal and Timeout after Three Wakeup Signals

The third and fourth types of timeout are related to the wakeup signal. A node initiating a wakeup should expect a header from the master within a defined amount of time: timeout after wakeup signal. See [Section 29.11.3](#) for more details.

### 29.7.8 TXRX Error Detector (TED)

The following sources of error are detected by the TXRX error detector logic (TED). The TED logic consists of a bit monitor, an ID parity checker, and a checksum error. The following errors are detected:

- Bit errors (BE)
- Physical bus errors (PBE)
- Identifier parity errors (PE)
- Checksum errors (CE)

All of these errors (BE, PBE, PE, CE) are flagged. An interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame.

### 29.7.8.1 Bit Errors

A bit error (BE) is detected at the bit time when the bit value that is monitored is different from the bit value that is sent. A bit error is indicated by the BE flag in SCIFLR. After signaling a BE, the transmission is aborted no later than the next byte. The bit monitor ensures that the transmitted bit in LINTX is the correct value on the LIN bus by reading back on the LINRX pin as shown in Figure 29-21.

**NOTE:** If BE Occurs due to New Header reception during a Slave Response, NRE/TIMEOUT flag will not be set for the new Frame.

**Figure 29-21. TXRX Error Detector**

### 29.7.8.2 Physical Bus Errors

A Physical Bus Error (PBE) has to be detected by a master if no valid message can be generated on the bus (Bus shorted to GND or VBAT). The bit monitor detects a PBE during the header transmission, if no Synch Break can be generated (for example, because of a bus shortage to VBAT) or if no Synch break Delimiter can be generated (for example, because of a bus shortage to GND). Once the Synch Break Delimiter was validated, all other deviations between the monitored and the sent bit value are flagged as Bit Errors (BE) for this frame.

### 29.7.8.3 ID Parity Errors

If parity is enabled, an ID parity error (PE) is detected if any of the two parity bits of the sent ID byte are not equal to the calculated parity on the receiver node. The two parity bits are generated using the following mixed parity algorithm.

$$P0 = ID0 \oplus ID1 \oplus ID2 \oplus ID4 \text{ (even Parity)}$$

$$P1 = ID1 \oplus ID3 \oplus ID4 \oplus ID5 \text{ (odd Parity)}$$

(52)

If an ID-parity error is detected, the ID-parity error is flagged, and the received ID is not valid. See Section 29.7.9 for details.

#### 29.7.8.4 Checksum Errors

A checksum error (CE) is detected and flagged at the receiving end if the calculated modulo-256 sum over all received data bytes (including the ID byte if it is the enhanced checksum type) plus the checksum byte does not result in 0xFF. The modulo-256 sum is calculated over each byte by adding with carry, where the carry bit of each addition is added to the LSB of its resulting sum.

For the transmitting node, the checksum byte sent at the end of a message is the inverted sum of all the data bytes (see Figure 29-22) for classic checksum implementation. The checksum byte is the inverted sum of the identifier byte and all the data bytes (see Figure 29-23) for the LIN 2.0 compliant enhanced checksum implementation. The classic checksum implementation should always be used for reserved identifiers 60 to 63; therefore, the CTYPE bit will be overridden in this case. For signal-carrying-frame identifiers (0 to 59) the type of checksum used depends on the CTYPE bit.

**Figure 29-22. Classic Checksum Generation at Transmitting Node**

**Figure 29-23. LIN 2.0-Compliant Checksum Generation at Transmitting Node**

### 29.7.9 Message Filtering and Validation

Message filtering uses the entire identifier to determine which nodes will participate in a response, either receiving or transmitting a response. Therefore, two acceptance masks are used, as shown in [Figure 29-24](#). During header reception, all nodes filter the ID-Field (ID-Field is the part of the header explained in [Figure 29-16](#)) to determine whether they transmit a response or receive a response for the current message. There are two masks for message ID filtering: one to accept a response reception, the other to initiate a response transmission. See [Figure 29-24](#). All nodes compare the received ID to the identifier stored in the ID-SlaveTask BYTE of the LINID register and use the RX ID MASK and the TX ID MASK fields in the LINMASK register to filter the bits of the identifier that should not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there will be an ID RX flag and an interrupt will be triggered if enabled. If there is a TX match with no parity error and the TXENA bit is set, there will be an ID TX flag and an interrupt will be triggered if enabled in the SCISSETINT register.

The masked bits become don't cares for the comparison. To build a mask for a set of identifiers, an XOR function could be used.

For example, to build a mask to accept IDs 0x26 and 0x25 using LINID[7:0] = 0x20; that is, compare 5 most significant bits (MSBs) and filter 3 least significant bits (LSBs), the acceptance mask could be:

$$(0x26 + 0x25) \oplus 0x20 = 0x07 \quad (53)$$

A mask of all zeros will compare all bits of the received identifier in the shift register with the ID-BYTE in LINID[7:0]. If HGEN CTRL is set to 1, a mask of 0xFF will always cause a match. A mask of all 1s will filter all bits of the received identifier, and thus there will be an ID match regardless of the content of the ID-SlaveTask BYTE field in the LINID register.

---

**NOTE:** When the HGEN CTRL bit = 0, the LIN nodes compare the received ID to the ID-BYTE field in the LINID register, and use the RX ID MASK and the TX ID MASK in the LINMASK register to filter the bits of the identifier that should not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there will be an ID RX flag and an interrupt will be triggered if enabled. A mask of all 0s will compare all bits of the received identifier in the shift register with the ID-BYTE field in LINID[7:0]. A mask of all 1s will filter all bits of the received identifier and there will be no match.

---

During header reception, the received identifier is copied to the Received ID field LINID[23:16]. If there is no parity error and there is either a TX match or an RX match, then the corresponding TX or RX ID flag is set. If the ID interrupt is enabled, then an ID interrupt is generated.

After the ID interrupt is generated, the CPU may read the Received ID field LINID[23:16] and determine what response to load into the transmit buffers.

---

**NOTE:** When byte 0 is written to TD0 (LINTD0[31:24]), the response transmission is automatically generated.

---

In multibuffer mode, the TXRDY flag will be set when all the response data bytes and checksum byte are copied to the shift register SCITXSHF. In non multibuffer mode, the TXRDY flag is set each time a byte is copied to the SCITXSHF register, and also for the last byte of the frame after the checksum byte is copied to the SCITXSHF register.

In multibuffer mode, the TXEMPTY flag is set when both the transmit buffer(s) TDy and the SCITXSHF shift register are emptied and the checksum has been sent. In non multibuffer mode, TXEMPTY is set each time TD0 and SCITXSHF are emptied, except for the last byte of the frame where the checksum byte must also be transmitted.

If parity is enabled, all slave receiving nodes will validate the identifier using all eight bits of the received ID byte. The SCI/LIN will flag a corrupted identifier if an ID-parity error is detected.

Figure 29-24. ID Reception, Filtering and Validation

### 29.7.10 Receive Buffers

To reduce CPU load when receiving a LIN N-byte (with N = 1–8) response in interrupt mode or DMA mode, the SCI/LIN module has eight receive buffers. These buffers can store an entire LIN response in the RDy receive buffers.

The checksum byte following the data bytes is validated by the internal checksum calculator. The checksum error (CE) flag indicates a checksum error and a CE interrupt will be generated if enabled in the SCISSETINT register.

The multibuffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers if multibuffer mode is enabled, or to RD0 if multibuffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be received. In cases where the ID BYTE field does not convey message length (see *Note:Optional Control Length Bits* in [Section 29.7.5](#)), the LENGTH value, indicates the expected length and is used to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMM MODE bit.

[Figure 29-8](#) illustrates the receive buffers.

A receive interrupt, and a receive ready RXRDY flag set as well as a DMA request (RXDMA) could occur after receiving a response if there are no response receive errors for the frame (such as, there is no checksum error, frame error, and overrun error). The checksum byte will be compared before acknowledging a reception. A DMA request can be generated for each received byte or for the entire response depending on whether the multibuffer mode is enabled or not (MBUF MODE bit).

- 
- NOTE:** In multibuffer mode following are the scenarios associated with clearing the "RXRDY" flag bit:
1. The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.
  2. For LENGTH less than or equal to 4, Read to RD0 register will clear the "RXRDY" flag.
  3. For LENGTH greater than 4, Read to RD1 register will clear the "RXRDY" flag.
- 

### 29.7.11 Transmit Buffers

To reduce the CPU load when transmitting a LIN N-byte (with N = 1–8) response in interrupt mode or DMA mode, the SCI/LIN module has eight transmit buffers, TD0–TD7 in LINTD0 and LINTD1. With these transmit buffers, an entire LIN response field can be preloaded in the TXy transmit buffers. Optionally, a DMA transfer could be done on a byte-per-byte basis when multibuffer mode is not enabled (MBUF MODE bit).

The multibuffer 3-bit counter counts the data bytes transferred from the TDy transmit buffers register if multibuffer mode is enabled, or from TD0 to SCITXSHF if multibuffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be transmitted. If the ID field is not used to convey message length (see *Note:Optional Control Length Bits* in [Section 29.7.5](#)), the LENGTH value indicates the expected length and is used instead to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMM MODE bit.

A transmit interrupt (TX interrupt), and a transmit ready flag (TXRDY flag), and a DMA request (TXDMA) could occur after transmitting a response. A DMA request can be generated for each transmitted byte or for the entire response depending on whether multibuffer mode is enabled or not (MBUF MODE bit).

[Figure 29-9](#) illustrates the transmit buffers.

The checksum byte will be automatically generated by the checksum calculator and sent after the data-fields transmission is finished. The multibuffer 3-bit counter counts the data bytes transferred from the TDy buffers into the SCITXSHF register.

- 
- NOTE:** The transmit interrupt request can be eliminated until the next series of data is written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt via the SCICLRINT register or by disabling the transmitter via the TXENA bit.
-

## 29.8 LIN Interrupts

LIN and SCI mode have a common Interrupt block as explained in [Section 29.3](#). There are 16 interrupt sources in the SCI/LIN module, with 8 of them being LIN mode only, as seen in [Table 29-4](#).

A LIN message frame indicating the timing and sequence of the LIN interrupts that could occur is shown in [Figure 29-25](#).

**Figure 29-25. LIN Message Frame Showing LIN Interrupt Timing and Sequence**

## 29.9 LIN DMA Interface

LIN DMA Interface uses the SCI DMA interface logic. DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. There are two modes for DMA transfers depending on whether multibuffer mode is enabled or not via the multibuffer enable control bit (MBUF MODE).

### 29.9.1 LIN Receive DMA Requests

In LIN mode, when the multibuffer option is enabled, if a received response (up to eight data bytes) is transferred to the receive buffers (RDy), then a DMA request is generated. If the multibuffer option is disabled, then DMA requests will be generated on a byte-per-byte basis until all the expected response data fields are received. This DMA functionality is enabled/disabled by the user using SET RX DMA / CLR RX DMA bits, respectively.

### 29.9.2 LIN Transmit DMA Requests

In LIN mode with the multibuffer option enabled, after a transmission (up to eight data bytes stored in the transmit buffer(s) TDy in the LINTD0 and LINTD1 registers), a DMA request is generated in order to reload the transmit buffer for the next transmission. If the multibuffer option is disabled, then DMA requests will be generated on a byte-per-byte basis until all bytes are transferred. This DMA functionality is enabled/disabled by the user using SET TX DMA / CLR TX DMA bits, respectively.

## 29.10 LIN Configurations

The following list details the configuration steps that software should perform prior to the transmission or reception of data in LIN mode. As long as SWnRST is held low the entire time that the LIN is being configured, the order in which the registers are programmed is not important.

- Enable LIN by setting RESET bit.
- Clear SWnRST to 0 before configuring the LIN.
- Configure the LINRX and LINTX pins as SCI functional by setting the RX FUNC and TX FUNC bit.
- Select LIN mode by programming LIN MODE bit.
- Select Master or Slave mode by programming the CLOCK bit.
- Select the desired frame format (checksum, parity, length control) by programming SCIGCR1.
- Select multi-buffer mode by programming MBUF MODE bit.
- Select the baud rate to be used for communication by programming BRSR.
- Set the Maximum baud rate to be used for communication by programming BRSR.
- Set the CONT bit to make LIN not to halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set LOOP BACK bit to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Select the receiver enable RXENA bit if data is to be received.
- Select the transmit enable TXENA bit if data is to be transmitted.
- Select the RX ID MASK and the TX ID MASK fields in the LINMASK register.
- Set SWnRST to 1 after the SCI is configured.
- Perform Receive or Transmit data (see [Section 29.7.9](#), [Section 29.7.10](#), or [Section 29.10.2](#)).

### 29.10.1 Receiving Data

The LIN receiver is enabled to receive messages if the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the LINRX pin functions as a general purpose I/O pin rather than as an SCI/LIN function pin.

ID RX flag is set after a valid LIN ID is received with RX Match, generated ID interrupt if enabled.

#### 29.10.1.1 Receiving Data in Single-Buffer Mode

Single Buffer Mode is selected when MBUF MODE bit is 0. In this mode SCI/LIN sets the RXRDY bit when it transfers newly received data from SCIRXSHF to RD0. The SCI clears the RXRDY bit after the new data in RD0 has been read. Also, as data is transferred from SCIRXSHF to RD0, the LIN sets FE, OE, or PE if any of these error conditions were detected in the received data. These error conditions are supported with configurable Interrupt capability.

User can read the Received data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for RXRDY bit and read the data from RD0 byte of LINRD0 register once RXRDY is set high. CPU is unnecessarily overloaded by selecting Polling mode. To avoid this user can use either Interrupt or DMA method. To use interrupt method SET RX INT bit should be set and to use DMA SET RX DMA bit should be set. Either an Interrupt or a DMA request is generated the moment RXRDY is set. If checksum scheme is used once Compare Checksum CC bit is set, the checksum will be compared on the byte that is currently being received, expected to be the checkbyte be enabled during the last byte of the data. CC bit will be cleared once Checksum is received. A CE will immediately be flagged if there is a checksum error.

### 29.10.1.2 Receiving Data in Multi-Buffer Mode

Multi-Buffer Mode is selected when MBUF MODE bit is 1. In this mode SCI/LIN sets the RXRDY bit after receiving the programmed number of data in the receive buffer and the checksum field, the complete frame. The error condition detection logic is same as Single Buffer mode, except that it monitors for the complete frame. Like Single Buffer mode the user can use either Interrupt, DMA or polling method to read the data. The received data has to be read from the LINRD0 and LINRD1 register, based on the number of bytes. For LENGTH less than or equal to 4, Read to LINRD0 register will clear the “RXRDY” flag. For LENGTH greater than 4, Read to LINRD1 register will clear the “RXRDY” flag. If checksum scheme is enabled by setting CC bit during the reception of the data, then the byte that is received after the reception of the programmed no. of data bytes indicated by LENGTH is treated as a checksum byte and compared.

### 29.10.2 Transmitting Data

The SCI transmitter is enabled if the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the LINTX pin functions as a general purpose I/O pin rather than as an SCI function pin. Any value written to the TD0 before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

ID TX flag is set after a valid LIN ID is received with TX Match, generated ID interrupt if enabled.

#### 29.10.2.1 Transmitting Data in Single-Buffer Mode

Single Buffer Mode is selected when MBUF MODE bit is 0. In this mode LIN waits for data to be written to TD0, transfers it to SCITXSHF, and transmits it. The flags TXRDY and TX EMPTY indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to TD0, the TXRDY bit is set. Additionally, if both TD0 and SCITXSHF are empty, then the TX EMPTY bit is also set.

User can transmit data by:

1. Polling Transmit Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for TXRDY bit to go high before writing the data to TD0 register. CPU is unnecessarily overloaded by doing this Polling method. To avoid this user can use either Interrupt or DMA method. To use interrupt method SET TX INT bit should be set and to use DMA SET TX DMA bit should be set. Either an Interrupt or a DMA request is generated the moment TXRDY is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and TD0 are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can be done by either disabling the transmit interrupt (CLR TX INT) / DMA request (CLR TX DMA bit) or by disabling the transmitter (clear TXENA bit). In checksum scheme once Send Checksum SC bit is set, the checksum will be sent after the current transmission.

---

**NOTE:** The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

---

#### 29.10.2.2 Transmitting Data in Multi-Buffer Mode

Multi-Buffer Mode is selected when MBUF MODE bit is 1. Similar to Single Buffer mode the software can use polling, Interrupt or DMA method to write the data to be transmitted. The data to be transmitted has to be written to LINTD0 and LINTD1 register, based on the number of bytes. SCI/LIN waits for data to be written to Byte 0(TD0) of LINTD0 register and transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically. In checksum scheme once Send Checksum SC bit is set, the checksum will be sent after transmission of programmed no. of data bytes indicated by LENGTH field.

## 29.11 Low-Power Mode

The SCI/LIN module can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN module. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive. If global low-power mode is requested while the receiver is receiving data, then the SCI/LIN completes the current reception and then enters the low-power mode, that is, module enters low power mode only when Busy bit (SCIFLR.3) is cleared.

The BLIN module may enter low power mode either when there was no activity on the LINRX pin for more than 4s (this can be either a constant recessive or dominant level) or when a Sleep Command frame was received. Once the Timeout flag (SCIFLR.4) was set or once a Sleep Command was received, the POWERDOWN bit (SCIGCR2.0) must be set by the application software to make the module enter local low-power mode. A wakeup signal will terminate the sleep mode of the LIN bus.

---

**NOTE: Enabling Local Low-Power Mode During Receive and Transmit**

If the wakeup interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI/LIN immediately generates a wake-up interrupt to clear the powerdown bit. Thus, the SCI/LIN is prevented from entering low-power mode and completes the current reception. Otherwise, if the wakeup interrupt is disabled, the SCI/LIN completes the current reception and then enters the low-power mode.

---

### 29.11.1 Entering Sleep Mode

In LIN protocol, a sleep command is used to broadcast the sleep mode to all nodes. The sleep command consists of a diagnostic master request frame with identifier 0x3C (60), with the first data field as 0x00. There should be no activity in the bus once all nodes receive the sleep command: the bus is in sleep mode.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and registers. Clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode. If a register is accessed in low-power mode, this access results in enabling the clock to the module for that particular access alone.

### 29.11.2 Wakeup

The wakeup interrupt is used to allow the SCI/LIN module to automatically exit low-power mode. A SCI/LIN wakeup is triggered when a low level is detected on the receive RX pin, and this clears the POWERDOWN bit.

**NOTE:** If the wakeup interrupt is disabled then the SCI/LIN enters low-power mode whenever it is requested to do so, but a low level on the receive RX pin does NOT cause the SCI/LIN to exit low-power mode.

In LIN mode, any node can terminate sleep mode by sending a wakeup signal; see Figure 29-26. A slave node that detects the bus in sleep mode, and with a wakeup request pending, will send a wakeup signal. The wakeup signal is a dominant value on the LIN bus for  $T_{WUSIG}$ ; this is at least  $5 T_{bits}$  for the LIN bus baud rates. The wakeup signal is generated by sending an 0xF0 byte containing 5 dominant  $T_{bits}$  and 5 recessive  $T_{bits}$ .

Figure 29-26. Wakeup Signal Generation

$$0.25\text{ms} \leq T_{WUSIG} \leq 5\text{ms}$$

(54)

Assuming a perfect bus with no noise or loading effects, a write of 0xF0 to TD0 will load the transmitter to meet the wakeup signal timing requirement for  $T_{WUSIG}$ . Then, setting the GENWU bit will transmit the preloaded value in TD0 for a wakeup signal transmission.

**NOTE:** The GENWU bit can be set/reset only when SWnRST is set to '1' and the node is in power down mode. The bit will be cleared on a valid synch break detection. A master sending a wakeup request, will exit power down mode upon reception of the wakeup pulse. The bit will be cleared on a SWnRST. This can be used to stop a master from sending further wakeup requests.

The TI TPIC1021 LIN transceiver, upon receiving a wakeup signal, will translate it to the microcontroller for wakeup with a dominant level on the RX pin, or a signal to the voltage regulator. While the POWERDOWN bit is set, if the LIN module detects a recessive-to-dominant edge (falling edge) on the RX pin, it will generate a wakeup interrupt if enabled in the SCISSETINT register.

According to LIN protocol 2.0, the TI TPIC1021 LIN transceiver detecting a dominant level on the bus longer than 150 ms will detect it as a wakeup request. The LIN controller's slave is ready to listen to the bus in less than 100 ms ( $T_{INITIALIZE} < 100\text{ms}$ ) after a dominant-to-recessive edge (end-of-wakeup signal).

### 29.11.3 Wakeup Timeouts

The LIN protocol defines the following timeouts for a wakeup sequence. After a wakeup signal has been sent to the bus, all nodes wait for the master to send a header. If no synch field is detected before 150 ms (3,000 cycles at 20 kHz) after wakeup signal is transmitted, a new wakeup is sent by the same node that requested the first wakeup. This sequence is not repeated more than two times. After three attempts to wake up the LIN bus, wakeup signal generation is suspended for a 1.5 s (30,000 cycles at 20 kHz) period after three breaks.

---

**NOTE:** To achieve compatibility to LIN1.3 timeout conditions, the MBRS register must be set to assure that the LIN 2.0 (real-time-based) timings meet the LIN 1.3 bit time base. A node triggering the wakeup should set the MBRS register accordingly to meet the targeted time as  $128 \text{ Tbits} \times \text{programmed prescaler}$ .

The LIN controller handles the wakeup expiration times defined by the LIN protocol with a hardware implementation.

---

### 29.12 Emulation Mode

In emulation mode, the CONT bit determines how the SCI/LIN operates when the program is suspended. The SCI/LIN counters are affected by this bit during debug mode. When set, the counters are not stopped and when cleared, the counters are stopped debug mode.

Any reads in emulation mode to a SCI/LIN register will not have any effect on the flags in the SCIFLR register.

---

**NOTE:** When emulation mode is entered during the Frame transmission or reception of the frame and CONT bit is not set, Communication is not expected to be successful. The suggested usage is to set CONT bit during emulation mode for successful communication.

---

## 29.13 SCI/LIN Control Registers

The SCI/LIN module registers are based on the SCI registers, with added functionality registers enabled by the LIN MODE bit in the SCIGCR1 register.

These registers are accessible in 8-, 16-, and 32-bit reads or writes. The SCI/LIN is controlled and accessed through the registers listed in [Table 29-9](#). Among the features that can be programmed are the LIN protocol mode, communication and timing modes, baud rate value, frame format, DMA requests, and interrupt configuration.

**Table 29-9. SCI/LIN Control Registers**

| Offset | Acronym        | Register Description                 | Section                            |

### 29.13.2 SCI Global Control Register 1 (SCIGCR1)

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI. Figure 29-28 and Table 29-11 illustrate this register.

**Figure 29-28. SCI Global Control Register 1 (SCIGCR1) [offset = 04h]**

| 25    | TXENA    | 0<br>1 | Transmit enable. This bit is effective in LIN and SCI modes. Data is transferred from SCITD, or the TDy (with y=0, 1,...7) buffers in LIN mode to the SCITXSHF shift out register only when the TXENA bit is set.<br>0 Transfers from SCITD or TDy to SCITXSHF are disabled.<br>1 Transfers from SCITD or TDy to SCITXSHF are enabled.<br><b>Note: Data written to SCITD or the transmit multi-buffer before TXENA is set is not transmitted. If TXENA is cleared while transmission is ongoing, the data previously written to SCITD is sent (including the checksum byte in LIN mode).</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 24    | RXENA    | 0<br>1 | Receive enable. This bit is effective in LIN and SCI modes. RXENA allows or prevents the transfer of data from SCIRXSHF to SCIRD or the receive multibuffers.<br>0 The receiver will not transfer data from the shift buffer to the receive buffer or multi-buffers.<br>1 The receiver will transfer data from the shift buffer to the receive buffer or multi-buffers.<br><b>Note: Clearing RXENA stops received characters from being transferred into the receive buffer or multi-buffers, prevents the RX status flags (see Table 29-10) from being updated by receive data, and inhibits both receive and error interrupts. However, the shift register continues to assemble data regardless of the state of RXENA.</b><br><b>Note: If RXENA is cleared before a frame is completely received, the data from the frame is not transferred into the receive buffer.</b><br><b>Note: If RXENA is set before a frame is completely received, the data from the frame is transferred into the receive buffer. If RXENA is set while SCIRXSHF is in the process of assembling a frame, the status flags are not guaranteed to be accurate for that frame. To ensure that the status flags correctly reflect what was detected on the bus during a particular frame, RXENA should be set before the detection of that frame.</b> |
| 23-18 | Reserved | 0      | Read returns 0. This bit is effective in LIN and SCI modes. The self-checking option for the SCI/LIN can be selected with this bit. If the LINITX and LINRX pins are configured with SCI/LIN functionality, then the LINITX pin is internally connected to the LINRX pin. Externally, during loop back operation, the LINITX pin outputs a high value and the LINRX pin is in a high-impedance state. If this bit value is changed while the SCI/LIN is transmitting or receiving data, errors may result.</p>                                                                                                                                                                                                               |
| 15-14 | Reserved       | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Read returns 0. This bit is effective in LIN and SCI modes. This bit controls receive/transmit buffer usage, that is, whether the RX/TX multibuffers are used or a single register, RD0/TD0, is used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 9     | ADAPT          | <p>0 Automatic baud rate adjustment is disabled.</p> <p>1 Automatic baud rate adjustment is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <p>Adapt. This mode is effective in LIN mode only. This bit has an effect during the detection of the synch field. Two LIN protocol bit rate modes could be enabled with this bit according to the node capability file definition: automatic or select. The software and network configuration will decide which of these two modes are enabled. When this bit is cleared, the LIN 2.0 protocol fixed bit rate should be used. If the ADAPT bit is set, a SCI/LIN slave node detecting the baud rate will compare it to the prescalers in BRS register and update it if they are different. The BRS register will be updated with the new value. If this bit is not set there will be no adjustment to the BRS register.</p> |
| 8     | SLEEP          | <p>0 Sleep mode is disabled.</p> <p>1 Sleep mode is enabled.</p> <p><b>Note: The receiver still operates when the SLEEP bit is set; however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags (see Table 29-10 ) are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition.</b></p> <p><b>Note: The SLEEP bit is not automatically cleared when an address byte is detected.</b></p> <p>See Section 29.6.1 for more information on using the SLEEP bit for multiprocessor communication.</p> | <p>SCI sleep. This bit is effective in SCI mode only. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI/LIN out of sleep mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Table 29-11. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)**

| Bit | Field       | Value            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----|-------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | SWnRST      | 0<br>1           | <p>Software reset (active low). This bit is effective in LIN and SCI modes.</p> <p>The SCI/LIN is in its reset state; no data will be transmitted or received. Writing a 0 to this bit initializes the SCI/LIN state machines and operating flags as defined in <a href="#">Table 29-12</a> and <a href="#">Table 29-13</a>. All affected logic is held in the reset state until a 1 is written to this bit.</p> <p>The SCI/LIN is in its ready state; transmission and reception can be done. After this bit is set to 1, the configuration of the module should not change.</p> <p><b>Note: The SCI/LIN should only be configured while SW nRESET = 0.</b></p>                                                                                                               |
| 6   | LIN MODE    | 0<br>1           | <p>LIN mode. This bit is effective in LIN and SCI mode. This bit controls the module mode of operation.</p> <p>LIN mode is disabled; SCI mode is enabled.</p> <p>LIN mode is enabled; SCI mode is disabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 5   | CLOCK       | 0<br>1<br>0<br>1 | <p>SCI internal clock enable. The CLOCK bit determines the source of the module clock on the SCICLK pin. It also determines whether a LIN node is a slave or master.</p> <p><i>SCI mode</i></p> <p>The external SCICLK is the clock source.</p> <p><b>Note: If an external clock is selected, then the internal baud rate generator and baud rate registers are bypassed. The maximum frequency allowed for an externally sourced SCI clock is VCLK/16.</b></p> <p>The internal SCICLK is the clock source.</p> <p><i>LIN mode</i></p> <p>The node is in slave mode.</p> <p>The node is in master mode.</p>                                                                                                                                                                    |
| 4   | STOP        | 0<br>1           | <p>SCI number of stop bits per frame. This bit is effective in SCI mode only.</p> <p>One stop bit is used.</p> <p>Two stop bits are used.</p> <p><b>Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit (if STOP = 1) to begin checking for an idle period.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 3   | PARITY      | 0<br>1           | <p>SCI parity odd/even selection. This bit is effective in SCI mode only. If the PARITY ENA bit is set, PARITY designates odd or even parity.</p> <p>Odd parity is used.</p> <p>Even parity is used.</p> <p><b>The parity bit is calculated based on the data bits in each frame and the address bit (in address-bit mode). The start and stop fields in the frame are not included in the parity calculation.</b></p> <p><b>For odd parity, the SCI transmits and expects to receive a value in the parity bit that makes odd the total number of bits in the frame with the value of 1.</b></p> <p><b>For even parity, the SCI transmits and expects to receive a value in the parity bit that makes even the total number of bits in the frame with the value of 1.</b></p> |
| 2   | PARITY ENA  | 0<br>1<br>0<br>1 | <p>Parity enable. This bit enables or disables the parity function.</p> <p><i>SCI or buffered SCI mode</i></p> <p>Parity is disabled; no parity bit is generated during transmission or is expected during reception.</p> <p>Parity is enabled. A parity bit is generated during transmission and is expected during reception.</p> <p><i>LIN mode</i></p> <p>ID field parity verification is disabled.</p> <p>ID field parity verification is enabled.</p>                                                                                                                                                                                                                                                                                                                    |
| 1   | TIMING MODE | 0<br>1           | <p>SCI timing mode bit. This bit is effective in SCI mode only. it selects the SCI timing mode.</p> <p>Synchronous timing is used.</p> <p>Asynchronous timing is used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 29-11. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)**

| Bit | Field     | Value | Description                                                                                                                                                              |
|-----|-----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | COMM MODE |       | SCI/LIN communication mode bit. In compatibility mode it selects the SCI communication mode. In LIN mode it selects length control option for ID-field bits ID4 and ID5. |
|     |           |       | <i>SCI mode</i>                                                                                                                                                          |
|     |           | 0     | Idle-line mode is used.                                                                                                                                                  |
|     |           | 1     | Address-bit mode is used.                                                                                                                                                |
|     |           |       | <i>LIN mode</i>                                                                                                                                                          |
|     |           | 0     | ID4 and ID5 are not used for length control.                                                                                                                             |
|     |           | 1     | ID4 and ID5 are used for length control.                                                                                                                                 |

**Table 29-12. SCI Receiver Status Flags**

| SCI Flag | Register | Bit | Value After SW nRESET <sup>(1)</sup> |
|----------|----------|-----|--------------------------------------|
| CE       | SCIFLR   | 29  | 0                                    |
| ISFE     | SCIFLR   | 28  | 0                                    |
| NRE      | SCIFLR   | 27  | 0                                    |
| FE       | SCIFLR   | 26  | 0                                    |
| OE       | SCIFLR   | 25  | 0                                    |
| PE       | SCIFLR   | 24  | 0                                    |
| RXWAKE   | SCIFLR   | 12  | 0                                    |
| RXRDY    | SCIFLR   | 9   | 0                                    |
| BUSY     | SCIFLR   | 3   | 0                                    |
| IDLE     | SCIFLR   | 2   | 0                                    |
| WAKE UP  | SCIFLR   | 1   | 0                                    |
| BRKDT    | SCIFLR   | 0   | 0                                    |

<sup>(1)</sup> The flags are frozen with their reset value while SW nRESET = 0.

**Table 29-13. SCI Transmitter Status Flags**

| SCI Flag | Register | Bit | Value After SW nRESET <sup>(1)</sup> |
|----------|----------|-----|--------------------------------------|
| BE       | SCIFLR   | 31  | 0                                    |
| PBE      | SCIFLR   | 30  | 0                                    |
| TX WAKE  | SCIFLR   | 10  | 0                                    |
| TX EMPTY | SCIFLR   | 11  | 1                                    |
| TXRDY    | SCIFLR   | 8   | 1                                    |

<sup>(1)</sup> The flags are frozen with their reset value while SW nRESET = 0.

### 29.13.3 SCI Global Control Register 2 (SCIGCR2)

The SCIGCR2 register is used to send or compare a checksum byte during extended frames, to generate a wakeup and for low-power mode control of the LIN module. [Figure 29-29](#) and [Table 29-14](#) illustrate this register.

**Figure 29-29. SCI Global Control Register 2 (SCIGCR2) [offset = 08h]**

|          |  |  |  |  |  |  |  |   |        |   |  |          |  |  |    |    |           |       |
|----------|--|--|--|--|--|--|--|---|--------|---|--|----------|--|--|----|----|-----------|-------|

| 31-18 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 17    | CC       | 0     | Compare checksum. LIN mode only. This bit is used by the receiver for extended frames to trigger a checksum compare. The user will initiate this transaction by writing a one to this bit. CC bit has to be set only after RX_RDY flag is set for the last received data.<br><br>In non-multibuffer mode, when the CC bit is set, the checksum will be compared on the byte that is expected to be the checksum byte.<br><br>During multi-buffer mode, the following scenarios are associated with the CC bit:<br><br>a) If the CC bit is set during the reception of the data, then the byte that is received after the reception of the programmed number of data bytes as indicated by SCIFORMAT[18:16] is treated as a checksum byte.<br><br>b) If the CC bit is set during the idle period (that is, during the inter-frame space), then the immediate next byte will be treated as a checksum byte.<br><br>c) CC bit will be auto cleared after the checkbyte has been received and compared. Checksum reception is not guaranteed if CC bit is write cleared by software during the checksum reception. See <a href="#">Section 29.7.6</a> for more details.           |
|       |          | 1     | No checksum compare will occur.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|       |          | 1     | Compare checksum on expected checksum byte.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 16    | SC       | 0     | Send checksum byte. This bit is effective in LIN mode only. This bit is used by the transmitter with extended frames to send a checksum byte. In non-multibuffer mode, the checksum byte will be sent after the current byte transmission. In multibuffer mode, the checksum byte will be sent after the last byte count, indicated by the SCIFORMAT[18:16]). See <a href="#">Section 29.7.6</a> for more details. This byte will be cleared after the checksum byte has been transmitted.<br><br>In non-multibuffer mode, the checksum byte will be sent after the current byte transmission.<br><br>During multi-buffer mode, the following scenarios are associated with the SC bit:<br><br>a) The checkbyte will be sent after the last byte count, indicated by the SCIFORMAT[18:16]).<br><br>b) Checksum will not be sent if SC is set before transmitting the very first byte(that is, during interframe space).<br><br>c) SC bit will be auto cleared after the checkbyte has been transmitted. Checksum transmission is not guaranteed if SC bit is write cleared by software during the checksum transmission. See <a href="#">Section 29.7.6</a> for more details. |
|       |          | 1     | No checksum byte will be sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|       |          | 1     | A checksum byte will be sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 29-14. SCI Global Control Register 2 (SCIGCR2) Field Descriptions (continued)**

| Bit | Field     | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|-----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | POWERDOWN |       | Power down. This bit is effective in LIN or SCI mode. When this bit is set, the SCI/LIN module attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wakeup interrupt is disabled, then the SCI/LIN will delay entering low-power mode until the reception is completed. In LIN mode, the user may set the POWERDOWN bit after receiving a sleep command or on idle bus detection (more than 4 seconds). See <a href="#">Section 29.11</a> for more information on low-power mode. |
|     |           | 0     | The SCI/LIN module is in normal operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|     |           | 1     | The SCI/LIN module enters local low-power mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### 29.13.4 SCI Set Interrupt Register (SCISSETINT)

[Figure 29-30](#) and [Table 29-15](#) illustrate this register. Refer [Figure 29-30](#) for details on when different interrupt flags get set in a frame during LIN Mode.

LEGEND: R/W = Read/Write; R = Read only; WL = Write in LIN mode only; WC = Write in SCI-compatible mode only; -n = value after reset

**Table 29-15. SCI Set Interrupt Register (SCISSETINT) Field Descriptions**

| Bit | Field       | Value | Description                                                                                                                                                                      |
|-----|-------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31  | SET BE INT  |       | Set bit error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is a bit error.                 |
|     |             | 0     | <i>Read:</i> The interrupt is disabled.                                                                                                                                          |
|     |             |       | <i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                             |
|     |             | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                  |
| 30  | SET PBE INT |       | Set physical bus error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when a physical bus error occurs. |
|     |             | 0     | <i>Read:</i> The interrupt is disabled.                                                                                                                                          |
|     |             |       | <i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                             |
|     |             | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                  |
| 29  | SET CE INT  |       | Set checksum-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is a checksum error.       |
|     |             | 0     | <i>Read:</i> The interrupt is disabled.                                                                                                                                          |
|     |             |       | <i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                             |
|     |             | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                  |

**Table 29-15. SCI Set Interrupt Register (SCISSETINT) Field Descriptions (continued)**

| Bit   | Field          | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|----------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 28    | SET ISFE INT   | 0<br>1 | Set inconsistent-synch-field-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is an inconsistent synch field error.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                     |
| 27    | SET NRE INT    | 0<br>1 | Set no-response-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when a no-response error occurs.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                  |
| 26    | SET FE INT     | 0<br>1 | Set framing-error interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when a framing error occurs.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                             |
| 25    | SET OE INT     | 0<br>1 | Set overrun-error interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when an overrun error occurs.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                            |
| 24    | SET PE INT     | 0<br>1 | Set parity interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when a parity error occurs.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                     |
| 23-19 | Reserved       | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 18    | SET RX DMA ALL | 0<br>1 | Set receive DMA all. This bit is effective in SCI-compatible mode only. This bit determines if a separate interrupt is generated for the address frames sent in multiprocessor communications. When this bit is 0, RX interrupt requests are generated for address frames and DMA requests are generated for data frames. When this bit is 1, RX DMA requests are generated for both address and data frames.<br><i>Read:</i> The DMA request is disabled for address frames (the receive interrupt request is enabled for address frames).<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read and write:</i> The DMA request is enabled for address and data frames. |
| 17    | SET RX DMA     | 0<br>1 | Set receiver DMA. This bit is effective in LIN or SCI-compatible mode. To enable receiver DMA requests, this bit must be set. If it is cleared, interrupt requests are generated depending on bit SCISSETINT.<br><i>Read:</i> The DMA request is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read and write:</i> The DMA request is enabled for address and data frames.                                                                                                                                                                                                                                                                                  |
| 16    | SET TX DMA     | 0<br>1 | Set transmit DMA. This bit is effective in LIN or SCI-compatible mode. To enable DMA requests for the transmitter, this bit must be set. If it is cleared, interrupt requests are generated depending on SET TX INT bit (SCISSETINT).<br><i>Read:</i> Transmit DMA request is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read and write:</i> Transmit DMA request is enabled.                                                                                                                                                                                                                                                                            |
| 15-14 | Reserved       | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table 29-15. SCI Set Interrupt Register (SCISSETINT) Field Descriptions (continued)**

| Bit   | Field           | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------|-----------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 13    | SET ID INT      | 0<br>1 | Set identification interrupt. This bit is effective in LIN mode only. This bit is set to enable an interrupt when a valid matching identifier is received. See <a href="#">Section 29.7.9</a> for more details.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                                                                       |
| 12-10 | Reserved        | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 9     | SET RX INT      | 0<br>1 | Receiver interrupt enable. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN to generate a receive interrupt after a frame has been completely received and the data is being transferred from SCIRXSHF to SCIRD.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                             |
| 8     | SET TX INT      | 0<br>1 | Set transmitter interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN to generate a transmit interrupt as data is being transferred from SCITD to SCITXSHF and the TXRDY bit is being set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                                             |
| 7     | SET TOA3WUS INT | 0<br>1 | Set timeout after three wakeup signals interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when a timeout occurs after three wakeup signals have been sent.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                                                              |
| 6     | SET TOAWUS INT  | 0<br>1 | Set timeout after wakeup signal interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when a timeout occurs after one wakeup signal has been sent.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                                                                         |
| 5     | Reserved        | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 4     | SET TIMEOUT INT | 0<br>1 | Set timeout interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when there is no LIN bus activity (bus idle) for at least four seconds.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                  |
| 3-2   | Reserved        | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 1     | SET WAKEUP INT  | 0<br>1 | Set wake-up interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN to generate a wakeup interrupt and thereby exit low-power mode. If enabled, the wakeup interrupt is asserted when local low-power mode is requested while the receiver is busy or if a low level is detected on the LINRX pin during low-power mode.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled. |
| 0     | SET BRKDT INT   | 0<br>1 | Set break-detect interrupt. This bit is effective in SCI-compatible mode only. Setting this bit enables the SCI/LIN to generate an error interrupt if a break condition is detected on the LINRX pin.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                 |

### 29.13.5 SCI Clear Interrupt Register (SCICLEARINT)

Figure 29-31 and Table 29-16 illustrate this register. SCICLEARINT register is used to clear the enabled interrupts without accessing SCISSETINT register.

**Figure 29-31. SCI Clear Interrupt Register (SCICLEARINT) [offset = 10h]**

LEGEND: R/W = Read/Write; R = Read only; WL = Write in LIN mode only; WC = Write in SCI-compatible mode only; -n = value after reset

**Table 29-16. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions**

| Bit | Field        | Value  | Description                                                                                                                                                                                                                                                                                                                            |
|-----|--------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31  | CLR BE INT   | 0<br>1 | Clear bit error interrupt. This bit is effective in LIN mode only. This bit disables the bit error interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                        |
| 30  | CLR PBE INT  | 0<br>1 | Clear physical bus error interrupt. This bit is effective in LIN mode only. This bit disables the physical-bus error interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.      |
| 29  | CLR CE INT   | 0<br>1 | Clear checksum-error interrupt. This bit is effective in LIN mode only. This bit disables the checksum interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                    |
| 28  | CLR ISFE INT | 0<br>1 | Clear inconsistent-synch-field-error (ISFE) interrupt. This bit is effective in LIN mode only. This bit disables the ISFE interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled. |

**Table 29-16. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions (continued)**

| Bit   | Field          | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|----------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 27    | CLR NRE INT    | 0<br>1 | Clear no-response-error interrupt. This bit is effective in LIN mode only. This bit disables the NRE interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                                                                                                                                                                                                                                                                         |
| 26    | CLR FE INT     | 0<br>1 | Clear framing-error interrupt. This bit is effective in LIN or SCI mode. This bit disables the framing-error interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                                                                                                                                                                                                                                                                 |
| 25    | CLR OE INT     | 0<br>1 | Clear overrun-error interrupt. This bit is effective in LIN or SCI mode. This bit disables the SCI/LIN overrun error interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                                                                                                                                                                                                                                                         |
| 24    | CLR PE INT     | 0<br>1 | Clear parity interrupt. This bit is effective in LIN or SCI mode. This bit disables the parity error interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                                                                                                                                                                                                                                                                         |
| 23-19 | Reserved       | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 18    | CLR RX DMA ALL | 0<br>1 | Clear receive DMA all. This bit is effective in SCI mode only. This bit clears the receive DMA request for address frames when set. Only receive data frames generate a DMA request.<br><i>Read:</i> Receive DMA request for address frames is disabled; Instead, RX interrupt requests are enabled for address frames. Receive DMA requests are still enabled for data frames.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The receive DMA request for address and data frames is enabled.<br><i>Write:</i> The receive DMA request for address and data frames is disabled. |
| 17    | CLR RX DMA     | 0<br>1 | Clear receive DMA request. This bit is effective in LIN or SCI mode. This bit disables the receive DMA request when set.<br><i>Read:</i> The DMA request is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The receive DMA request is enabled.<br><i>Write:</i> The receive DMA request for is disabled.                                                                                                                                                                                                                                                               |
| 16    | CLR TX DMA     | 0<br>1 | Clear transmit DMA request. This bit is effective in LIN or SCI mode. This bit disables the transmit DMA request when set.<br><i>Read:</i> Transmit DMA request is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The transmit DMA request is enabled.<br><i>Write:</i> The transmit DMA request for is disabled.                                                                                                                                                                                                                                                      |
| 15-14 | Reserved       | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Table 29-16. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions (continued)**

| Bit   | Field           | Value  | Description                                                                                                                                                                                                                                                                                                                                                                        |
|-------|-----------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 13    | CLR ID INT      | 0<br>1 | <p>Clear ID interrupt. This bit is effective in LIN mode only. This bit disables the ID interrupt when set.</p> <p><i>Read:</i> The interrupt is disabled.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> The interrupt is enabled.<br/><i>Write:</i> The interrupt is disabled.</p>                                                                 |
| 12-10 | Reserved        | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                             |
| 9     | CLR RX INT      | 0<br>1 | <p>Clear receiver interrupt. This bit is effective in LIN or SCI mode. This bit disables the receiver interrupt when set.</p> <p><i>Read:</i> The interrupt is disabled.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> The interrupt is enabled.<br/><i>Write:</i> The interrupt is disabled.</p>                                                   |
| 8     | CLR TX INT      | 0<br>1 | <p>Clear transmitter interrupt. This bit is effective in LIN or SCI mode. This bit disables the transmitter interrupt when set.</p> <p><i>Read:</i> The interrupt is disabled.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> The interrupt is enabled.<br/><i>Write:</i> The interrupt is disabled.</p>                                             |
| 7     | CLR TOA3WUS INT | 0<br>1 | <p>Clear timeout after three wakeup signals interrupt. This bit is effective in LIN mode only. This bit disables the timeout after three wakeup signals interrupt when set.</p> <p><i>Read:</i> The interrupt is disabled.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> The interrupt is enabled.<br/><i>Write:</i> The interrupt is disabled.</p> |
| 6     | CLR TOAWUS INT  | 0<br>1 | <p>Clear timeout after wakeup signal interrupt. This bit is effective in LIN mode only. This bit disables the timeout after one wakeup signal interrupt when set.</p> <p><i>Read:</i> The interrupt is disabled.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> The interrupt is enabled.<br/><i>Write:</i> The interrupt is disabled.</p>           |
| 5     | Reserved        | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                             |
| 4     | CLR TIMEOUT INT | 0<br>1 | <p>Clear timeout interrupt. This bit is effective in LIN mode only. This bit disables the timeout (LIN bus idle) interrupt when set.</p> <p><i>Read:</i> The interrupt is disabled.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> The interrupt is enabled.<br/><i>Write:</i> The interrupt is disabled.</p>                                        |
| 3-2   | Reserved        | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                             |
| 1     | CLR WAKEUP INT  | 0<br>1 | <p>Clear wake-up interrupt. This bit is effective in LIN or SCI-compatible mode. This bit disables the wakeup interrupt when set.</p> <p><i>Read:</i> The interrupt is disabled.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> The interrupt is enabled.<br/><i>Write:</i> The interrupt is disabled.</p>                                           |

**Table 29-16. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions (continued)**

| Bit | Field         | Value  | Description                                                                                                                                                                                                                                                                                                                      |
|-----|---------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | CLR BRKDT INT | 0<br>1 | Clear break-detect interrupt. This bit is effective in SCI-compatible mode only. This bit disables the break-detect interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled. |

### 29.13.6 SCI Set Interrupt Level Register (SCISSETINTLVL)

Figure 29-32 and Table 29-17 illustrate this register.

**Figure 29-32. SCI Set Interrupt Level Register (SCISSETINTLVL) [offset = 14h]**

**Table 29-17. SCI Set Interrupt Level Register (SCISSETINTLVL) Field Descriptions**

| Bit | Field            | Value  | Description                                                                                                                                                                                                                                                                                  |
|-----|------------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31  | SET BE INT LVL   | 0<br>1 | Set bit error interrupt level. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt level is mapped to the INT1 line.                      |
| 30  | SET PBE INT LVL  | 0<br>1 | Set physical bus error interrupt level. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt level is mapped to the INT1 line.             |
| 29  | SET CE INT LVL   | 0<br>1 | Set checksum-error interrupt level. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt level is mapped to the INT1 line.                 |
| 28  | SET ISFE INT LVL | 0<br>1 | Set inconsistent-synch-field-error interrupt level. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt level is mapped to the INT1 line. |

**Table 29-17. SCI Set Interrupt Level Register (SCISSETINTLVL) Field Descriptions (continued)**

| Bit   | Field               | Value  | Description                                                                                                                                                                                                                                                                                                                              |
|-------|---------------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 27    | SET NRE INT LVL     | 0<br>1 | Set no-response-error interrupt level. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt level is mapped to the INT1 line.                                                          |
| 26    | SET FE INT LVL      | 0<br>1 | Set framing-error interrupt level. This bit is effective in LIN or SCI-compatible mode.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt level is mapped to the INT1 line.                                                 |
| 25    | SET OE INT LVL      | 0<br>1 | Set overrun-error interrupt level. This bit is effective in LIN or SCI-compatible mode.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt level is mapped to the INT1 line.                                                 |
| 24    | SET PE INT LVL      | 0<br>1 | Set parity error interrupt level. This bit is effective in LIN or SCI-compatible mode.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt level is mapped to the INT1 line.                                                  |
| 23-19 | Reserved            | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                   |
| 18    | SET RX DMA ALL LVL  | 0<br>1 | Set receive DMA all interrupt levels. This bit is effective in SCI mode only.<br><i>Read:</i> The receive interrupt request for address frames is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The receive interrupt request for address frames is mapped to the INT1 line. |
| 17-14 | Reserved            | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                   |
| 13    | SET ID INT LVL      | 0<br>1 | Set ID interrupt level. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt level is mapped to the INT1 line.                                                                         |
| 12-10 | Reserved            | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                   |
| 9     | SET RX INT LVL      | 0<br>1 | Set receiver interrupt level. This bit is effective in LIN or SCI-compatible mode.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt level is mapped to the INT1 line.                                                      |
| 8     | SET TX INT LVL      | 0<br>1 | Set transmitter interrupt level. This bit is effective in LIN or SCI-compatible mode.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt level is mapped to the INT1 line.                                                   |
| 7     | SET TOA3WUS INT LVL | 0<br>1 | Set timeout after three wakeup signals interrupt level. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt level is mapped to the INT1 line.                                         |
| 6     | SET TOAWUS INT LVL  | 0<br>1 | Set timeout after wakeup signal interrupt level. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt level is mapped to the INT1 line.                                                |
| 5     | Reserved            | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                   |

| 31  | BE    | <p>0</p> <p>1</p> | <p>Bit error flag. This bit is effective in LIN mode only. This bit is set when a bit error has occurred. This is detected by the internal bit monitor. See <a href="#">Section 29.7.8</a> for more information. The bit error flag is cleared by any of the following:</p> <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>On reception of a new synch break</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p><i>Read:</i> No error has been detected since this bit was last cleared.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> An error has been detected since this bit was last cleared.</p> <p><i>Write:</i> The bit is cleared to 0.</p>                                                                                                                                                                                                                                             |
