| 30  | PBE   | <p>0</p> <p>1</p> | <p>Physical bus error flag. This bit is effective in LIN mode only. This bit is set when a physical bus error has been detected by the bit monitor in TED. See <a href="#">Section 29.7.8</a> for more information. The physical bus error flag is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>On reception of a new synch break</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p><b>Note: The PBE will only be flagged, if no Synch Break can be generated (for example, because of a bus shortage to VBAT) or if no Synch Break Delimiter can be generated (for example, because of a bus shortage to GND).</b></p> <p><i>Read:</i> No error has been detected since this bit was last cleared.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> An error has been detected since this bit was last cleared.</p> <p><i>Write:</i> The bit is cleared to 0.</p> |

**Table 29-19. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit | Field | Value                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----|-------|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 29  | CE    | <div>0</div> <div>1</div> | <p>Checksum error flag. This bit is effective in LIN mode only. This bit is set when a checksum error has been detected by a receiving node. This error is detected by the TED logic. See <a href="#">Section 29.7.8</a> for more information. The type of checksum to be used depends on the CTYPE bit in SCIGCR1. The checksum error flag is cleared by the following:</p> <ul style="list-style-type: none"><li>• Setting of the SW nRST bit</li><li>• Setting of the RESET bit</li><li>• A system reset</li><li>• Writing a 1 to this bit</li><li>• Reception of a new synch break</li><li>• Reading the corresponding interrupt offset in SCIINTVECT0/1</li></ul> <p><i>Read:</i> No error has been detected since this bit was last cleared.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> An error has been detected since this bit was last cleared.<br/><i>Write:</i> The bit is cleared to 0.</p>                         |
| 28  | ISFE  | <div>0</div> <div>1</div> | <p>Inconsistent synch field error flag. This bit is effective in LIN mode only. This bit is set when an inconsistent synch field error has been detected by the synchronizer during header reception. See <a href="#">Section 29.7.5.2</a> for more information. The inconsistent synch field error flag is cleared by the following:</p> <ul style="list-style-type: none"><li>• Setting of the SW nRST bit</li><li>• Setting of the RESET bit</li><li>• A system reset</li><li>• Writing a 1 to this bit</li><li>• Reception of a new synch break</li><li>• Reading the corresponding interrupt offset in SCIINTVECT0/1</li></ul> <p><i>Read:</i> No inconsistent synch field error has been detected.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> An inconsistent synch field error has been detected.<br/><i>Write:</i> The bit is cleared to 0.</p>                                                                          |
| 27  | NRE   | <div>0</div> <div>1</div> | <p>No-response error flag. This bit is effective in LIN mode only. This bit is set when there is no response to a master's header completed within TFRAME_MAX. This timeout period is applied for message frames of known length (identifiers 0 to 61). This error is detected by the synchronizer. See <a href="#">Section 29.7.7</a> for more information. The no-response error flag is cleared by the following:</p> <ul style="list-style-type: none"><li>• Setting of the SW nRST bit</li><li>• Setting of the RESET bit</li><li>• A system reset</li><li>• Writing a 1 to this bit</li><li>• Reception of a new synch break</li><li>• Reading the corresponding interrupt offset in SCIINTVECT0/1</li></ul> <p><i>Read:</i> No no-response error has been detected since the last clear.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> A no-response error has been detected.<br/><i>Write:</i> The bit is cleared to 0.</p> |

**Table 29-19. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit   | Field    | Value                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|----------|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26    | FE       | <div>0</div> <div>1</div> | <p>Framing error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when an expected stop bit is not found. In SCI compatibility mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI/LIN to generate an error interrupt if the SET FE INT bit is set in the register SCISSETINT. The framing error flag is cleared by the following:</p> <ul style="list-style-type: none"><li>Setting of the SW nRST bit</li><li>Setting of the RESET bit</li><li>A system reset</li><li>Writing a 1 to this bit</li><li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li><li>Reception of a new character/frame, depending on whether the module is in SCI compatible or LIN mode</li></ul> <p>In multibuffer mode the frame is defined in the SCIFORMAT register.</p> <p><i>Read:</i> No framing error has been detected since the last clear.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> A framing error has been detected since the last clear.</p> <p><i>Write:</i> The bit is cleared to 0.</p>                                                                |
| 25    | OE       | <div>0</div> <div>1</div> | <p>Overrun error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD or the RDy buffers in LINRD0 and LINRD1. Detection of an overrun error causes the LIN to generate an error interrupt if the SET OE INT bit = 1. The OE flag is reset by the following:</p> <ul style="list-style-type: none"><li>Setting of the SW nRST bit</li><li>Setting of the RESET bit</li><li>A system reset</li><li>Writing a 1 to this bit</li><li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li></ul> <p><i>Read:</i> No overrun error has been detected since the last clear.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> An overrun error has been detected.</p> <p><i>Write:</i> The bit is cleared to 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 24    | PE       | <div>0</div> <div>1</div> | <p>Parity error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. If the parity function is disabled (SCIGCR[2] = 0), the PE flag is disabled and read as 0. Detection of a parity error causes the LIN to generate an error interrupt if the SET PE INT bit = 1. The PE bit is reset by the following:</p> <ul style="list-style-type: none"><li>Setting of the SW nRST bit</li><li>Setting of the RESET bit</li><li>A system reset</li><li>Writing a 1 to this bit</li><li>Reception of a new character or frame, depending on whether the module is in SCI compatible or LIN mode, respectively.</li><li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li></ul> <p><i>Read:</i> No parity error has been detected since the last clear.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> A parity error has been detected.</p> <p><i>Write:</i> The bit is cleared to 0.</p> |
| 23-15 | Reserved | 0                         | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 29-19. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit | Field      | Value                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|------------|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14  | ID RX FLAG | <p>0</p> <p>1</p>                   | <p>Identifier on receive flag. This bit is effective in LIN mode only. This flag is set once an identifier is received with an receive match and no ID-parity error. See <a href="#">Section 29.7.9</a> for more details. This flag indicates that a new valid identifier has been received on an RX match. This bit is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the LINID register</li> <li>Reception of a new synch break</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p><i>Read:</i> No valid ID has been received since the last clear.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> A valid ID RX has been received in LINID[23:16] on an RX match.</p> <p><i>Write:</i> The bit is cleared to 0.</p> |
| 13  | ID TX FLAG | <p>0</p> <p>1</p>                   | <p>Identifier on transmit flag. This bit is effective in LIN mode only. This flag is set when an identifier is received with a transmit match and no ID-parity error. See <a href="#">Section 29.7.9</a> for more details. This flag indicates that a new valid identifier has been received on a TX match. This bit is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the LINID register</li> <li>Receiving a new synch break</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p><i>Read:</i> No valid ID has been received since the last clear.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> A valid ID TX has been received in LINID[23:16] on an TX match.</p> <p><i>Write:</i> The bit is cleared to 0.</p>       |
| 12  | RXWAKE     | <p>0</p> <p>1</p>                   | <p>Receiver wakeup detect flag. This bit is effective in SCI-compatible mode only. The SCI sets this bit to indicate that the data currently in SCIRD is an address. RXWAKE is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Upon receipt of a data frame.</li> </ul> <p><i>0</i> The data in SCIRD is not an address.</p> <p><i>1</i> The data in SCIRD is an address.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 11  | TX EMPTY   | <p>0</p> <p>1</p> <p>0</p> <p>1</p> | <p>Transmitter empty flag. This flag indicates the transmitter's buffer register(s) (SCITD/TDy) and shift register (SCITXSHF) are empty. In multibuffer mode, this flag indicates the TDx registers and shift register (SCITXSHF) are empty. In non-multibuffer mode, this flag indicates the LINTD0 byte and the shift register (SCITXSHF) are empty.</p> <p><b>Note: The RESET bit, an active SW nRESET (SCIGCR1[7]) or a system reset sets this bit. This bit does not cause an interrupt request.</b></p> <p><i>SCI mode or LIN non-multibuffer mode</i></p> <p><i>0</i> Transmitter buffer or shift register (or both) are loaded with data.</p> <p><i>1</i> Transmitter buffer and shift registers are both empty.</p> <p><i>In LIN mode using multibuffer mode</i></p> <p><i>0</i> Multibuffer or shift register (or all) are loaded with data</p> <p><i>1</i> Multibuffer and shift registers are all empty.</p>                             |

**Table 29-19. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit | Field  | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----|--------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10  | TXWAKE |       | <p>Transmitter wakeup method select. This bit is effective in SCI mode only. The TXWAKE bit controls whether the data in SCITD should be sent as an address or data frame using multiprocessor communication format. This bit is set to 1 or 0 by software before a byte is written to SCITD and is cleared by the SCI when data is transferred from SCITD to SCITXSHF or by a system reset.</p> <p><b>Note: TXWAKE is not cleared by the SW nRESET bit.</b></p> <p><i>Address-bit mode</i></p> <p>0 Frame to be transmitted will be data (address bit = 0).</p> <p>1 Frame to be transmitted will be an address (address bit = 1).</p> <p><i>Idle-line mode</i></p> <p>0 The frame to be transmitted will be data.</p> <p>1 The following frame to be transmitted will be an address (writing a 1 to this bit followed by writing dummy data to the SCITD will result in a idle period of 11 bit periods before the next frame is transmitted).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 9   | RXRDY  |       | <p>Receiver ready flag. In SCI-compatible mode, the receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU. In <i>LIN mode</i>, RXRDY is set once a valid frame is received in multibuffer mode, a valid frame being a message frame received with no errors. In <i>non-multibuffer mode</i>, RXRDY is set for each received byte and will be set for the last byte of the frame if there are no errors. The SCI/LIN generates a receive interrupt when RXRDY flag bit is set if the interrupt-enable bit is set (SCISSETINT[9]); RXRDY is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the SCIRD register in compatibility mode</li> <li>Reading the last data byte RDY of the response in LIN mode</li> </ul> <p><b>Note: The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</b></p> <p>0 <i>Read:</i> No new data is in SCIRD.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p>1 <i>Read:</i> New data is ready to be read from SCIRD.<br/><i>Write:</i> The bit is cleared to 0.</p>                                                                                                                                                                                                                                                                                          |
| 8   | TXRDY  |       | <p>Transmitter buffer register ready flag. When set, this bit indicates that the transmit buffer(s) register(s) (SCITD in compatibility mode and LINTD0/LINTD1 in multibuffer mode) are ready to get another character from a CPU write.</p> <p><i>In SCI</i>, writing data to SCITD automatically clears this bit. <i>In LIN mode</i>, this bit is cleared once byte 0 (TD0) is written to LINTD0. This bit is set after the data of the TX buffer is shifted into the SCITXSHF register. This event can trigger a transmit interrupt after data is copied to the TX shift register SCITXSHF, if the interrupt enable bit TXINT is set.</p> <p><b>Note:</b></p> <p>1) TXRDY is also set to 1 either by setting of the RESET bit, enabling SW nRST or by a system reset.</p> <p>2) The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</p> <p>3) The transmit interrupt request can be eliminated until the next series of data written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt via the SCICLEARINT register or by disabling the transmitter via the TXENA bit.</p> <p><i>SCI mode</i></p> <p>0 SCITD is full.</p> <p>1 SCITD is ready to receive the next character.</p> <p><i>LIN mode</i></p> <p>0 The multibuffers are full.</p> <p>1 The multibuffers are ready to receive the next character(s).</p> <p>For more information on transmit interrupt handling, see the SCI document for compatibility mode and <a href="#">Section 29.7.9</a> for LIN mode.</p> |

**Table 29-19. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit | Field    | Value             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|----------|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | TOA3WUS  | <p>0</p> <p>1</p> | <p>Timeout after three wakeup signals flag. This bit is effective in LIN mode only. This flag is set if there is no synch break received after three wakeup signals and a period of 1.5 seconds has passed. Such expiration time is used before issuing another round of wakeup signals. This bit is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p>See <a href="#">Section 29.11.3</a> for more information.</p> <p><i>Read:</i> No timeout occurred after three wakeup signals.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> Timeout occurred after three wakeup signals and 1.5 seconds time.</p> <p><i>Write:</i> The bit is cleared to 0.</p> |
| 6   | TOAWUS   | <p>0</p> <p>1</p> | <p>Timeout after wakeup signal flag. This bit is effective in LIN mode only. This bit is set if there is no synch break received after a wakeup signal has been sent. A minimum of 150 ms expiration time is used before issuing another wakeup signal. This bit is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset occurring</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p>See <a href="#">Section 29.11.3s</a> for more information.</p> <p><i>Read:</i> No timeout occurred after one wakeup signal (150ms).</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> Timeout occurred after one wakeup signal.</p> <p><i>Write:</i> The bit is cleared to 0.</p>                                             |
| 5   | Reserved | 0                 | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 4   | TIMEOUT  | <p>0</p> <p>1</p> | <p>LIN bus idle timeout flag. This bit is effective in LIN mode only. This bit is set earliest after at least four seconds of bus inactivity. Bus inactivity is defined as no transactions between recessive and dominant (and vice versa). This bit is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset occurring</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p>See <a href="#">Section 29.7.7</a> for more information.</p> <p><i>Read:</i> No bus idle has been detected since this bit was last cleared.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> A LIN bus idle has been detected.</p> <p><i>Write:</i> The bit is cleared to 0.</p>                                                         |
| 3   | BUSY     | <p>0</p> <p>1</p> | <p>Bus busy flag. This bit is effective in LIN mode and SCI-compatible mode. This bit indicates whether the receiver is in the process of receiving a frame. As soon as the receiver detects the beginning of a start bit, the BUSY bit is set to 1. When the reception of a frame is complete, the SCI/LIN clears the BUSY bit. If SET WAKEUP INT is set and power down is requested while this bit is set, the SCI/LIN automatically prevents low-power mode from being entered and generates wakeup interrupt. The BUSY bit is controlled directly by the SCI/LIN receiver, but this bit can also be cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset occurring</li> </ul> <p><i>0</i> The receiver is not currently receiving a frame.</p> <p><i>1</i> The receiver is currently receiving a frame.</p>    |

**Table 29-19. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit | Field  | Value                                                                                                                                                                                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | IDLE   | <p>0 The idle period has been detected; the SCI is ready to receive.</p> <p>1 The idle period has not been detected; the SCI will not receive any data.</p>                                                                                     | <p>SCI receiver in idle state. This bit is effective in SCI-compatible mode only. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters the idle state if one of the following events occurs:</p> <ul style="list-style-type: none"> <li>• A system reset</li> <li>• An SCI software reset</li> <li>• A power down</li> <li>• The RX pin is configured as a general I/O pin</li> </ul>                                                                                                                                                      |
| 1   | WAKEUP | <p>0 <i>Read:</i> The module will not wake up from power-down mode.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p>1 <i>Read:</i> Wake up from power-down mode.<br/><i>Write:</i> The bit is cleared to 0.</p>                 | <p>Wakeup flag. This bit is effective in LIN mode only. This bit is set by the SCI/LIN when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit (SCISSETINT[2]) is set. It is cleared by the following:</p> <ul style="list-style-type: none"> <li>• Setting of the SW nRST bit</li> <li>• Setting of the RESET bit</li> <li>• A system reset</li> <li>• Writing a 1 to this bit</li> <li>• Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p>For compatibility mode, see the SCI document for more information on low-power mode.</p>                                                                                      |
| 0   | BRKDT  | <p>0 <i>Read:</i> No break condition has been detected since the last clear.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p>1 <i>Read:</i> A break condition has been detected.<br/><i>Write:</i> The bit is cleared to 0.</p> | <p>SCI break-detect flag. This bit is effective in SCI-compatible mode only. This bit is set when the SCI detects a break condition on the LINRX pin. A break condition occurs when the LINRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the BRKDT INT ENA bit is set. The BRKDT bit is reset by the following:</p> <ul style="list-style-type: none"> <li>• Setting of the SW nRST bit</li> <li>• Setting of the RESET bit</li> <li>• A system reset</li> <li>• Writing a 1 to this bit</li> <li>• Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> |

### 29.13.9 SCI Interrupt Vector Offset 0 (SCIINTVECT0)

Figure 29-35 and Table 29-20 illustrate this register.

**Figure 29-35. SCI Interrupt Vector Offset 0 (SCIINTVECT0) [offset = 20h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 29-20. SCI Interrupt Vector Offset 0 (SCIINTVECT0) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|       |          | 5h    | The character is 6 bits long.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|       |          | 6h    | The character is 7 bits long.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|       |          | 7h    | The character is 8 bits long.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### 29.13.12 Baud Rate Selection Register (BRS)

This section describes the baud rate selection register. [Figure 29-38](#) and [Table 29-23](#) illustrate this register.

**Figure 29-38. Baud Rate Selection Register (BRS) [offset = 2Ch]**

| 30-28 | U           | 0-2h       | SCI/LIN super fractional divider selection. These bits are effective in LIN or SCI asynchronous mode. These bits are an additional fractional part for the baud rate specification. These bits allow a super-fine tuning of the fractional baud rate with seven more intermediate values for each of the M fractional divider values. See <a href="#">Section 29.7.4.1</a> for more details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 27-24 | M           | 0-3h       | SCI/LIN 4-bit fractional divider selection. These bits are effective in LIN or SCI asynchronous mode. These bits are used to select a baud rate for the SCI/LIN module, and they are a fractional part for the baud rate specification. The M divider allows fine-tuning of the baud rate over the P prescaler with 15 additional intermediate values for each of the P integer values. See <a href="#">Section 29.7.4.1</a> for more details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 23-0  | PRESCALER P | 0-FF FFFFh | <p>These bits are used to select a baud rate for the SCI/LIN module. These bits are effective in LIN mode and SCI compatibility..</p> <p>The SCI/LIN has an internally generated serial clock determined by the VCLK and the prescalers P and M in this register. The LIN uses the 24-bit integer prescaler P value of this register to select one of over 16,700,000. The additional 4-bit fractional divider M refines the baudrate selection PRESCALER[27:24].</p> <p><b>NOTE: In LIN mode, ONLY the asynchronous mode and baudrate values are used.</b></p> <p>The baud rate can be calculated using the following formulas:</p> $\text{Asynchronous baud value} = \left( \frac{\text{VCLK Frequency}}{16 \left( P + 1 + \frac{M}{16} \right)} \right) \quad (55)$ $\text{Isosynchronous baud value} = \left( \frac{\text{VCLK Frequency}}{P + 1} \right) \quad (56)$ <p>For P = 0,</p> $\text{Asynchronous baud value} = \left( \frac{\text{VCLK Frequency}}{32} \right) \quad (57)$ $\text{Isosynchronous baud value} = \left( \frac{\text{VCLK Frequency}}{2} \right) \quad (58)$ <p><a href="#">Table 29-24</a> contains comparative baud values for different P values, with VCLK = 50 MHz, for asynchronous mode.</p> |

**Table 29-24. Comparative Baud Values for Different P Values, Asynchronous Mode<sup>(1)(2)</sup>**

| 24-Bit Register Value |        | Baud Selected |        | PercentError |
|-----------------------|--------|---------------|--------|--------------|
| Decimal               | Hex    | Ideal         | Actual |              |
| 26                    | 00001A | 115200        | 115740 | 0.47         |
| 53                    | 000035 | 57600         | 57870  | 0.47         |
| 80                    | 000050 | 38400         | 38580  | 0.47         |
| 162                   | 0000A2 | 19200         | 19172  | -0.15        |
| 299                   | 00012B | 10400         | 10417  | 0.16         |
| 325                   | 000145 | 9600          | 9586   | -0.15        |
| 399                   | 00018F | 7812.5        | 7812.5 | 0.00         |
| 650                   | 00028A | 4800          | 4800   | 0.00         |
| 15624                 | 003BA0 | 200           | 200    | 0.00         |
| 624999                | 098967 | 5             | 5      | 0.00         |

<sup>(1)</sup> VCLK = 50 MHz

<sup>(2)</sup> Values are in decimal except for column 2.

### 29.13.13 SCI Data Buffers (SCIED, SCIRD, SCITD)

The SCI has three addressable registers in which transmit and receive data is stored. These three registers are available in SCI mode only.

#### 29.13.13.1 Receiver Emulation Data Buffer (SCIED)

The SCIED register is addressed at a location different from SCIRD, but is physically the same register. [Figure 29-39](#) and [Table 29-25](#) illustrate this register.

**Figure 29-39. Receiver Emulation Data Buffer (SCIED) [offset = 30h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 29-25. Receiver Emulation Data Buffer (SCIED) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                             |
|------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                  |
| 7-0  | ED       | 0-FFh | Emulator data. This bit is effective in SCI-compatible mode only. Reading SCIED[7:0] does not clear the RXRDY flag, unlike reading SCIRD. This register should be used only by an emulator that must continually read the data buffer without affecting the RXRDY flag. |

### 29.13.13.2 Receiver Data Buffer (SCIRD)

This register provides a location for the receiver data. [Figure 29-40](#) and [Table 29-26](#) illustrate this register.

**Figure 29-40. Receiver Data Buffer (SCIRD) [offset = 34h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 29-26. Receiver Data Buffer (SCIRD) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|------|----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                             |
| 7-0  | RD       | 0-FFh | Receiver data. This bit is effective in SCI-compatible mode only. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag is set and a receive interrupt is generated if SET RX INT is set.<br><b>Note: When the data is read from SCIRD, the RXRDY flag is automatically cleared.</b> |

**NOTE:** When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left justified format padded with trailing zeros. Therefore, the user software should perform a logical shift on the data by the correct number of positions to make it right justified.

### 29.13.13.3 Transmit Data Buffer Register (SCITD)

Data to be transmitted is written to the SCITD register. [Figure 29-41](#) and [Table 29-27](#) illustrate this register.

**Figure 29-41. Transmit Data Buffer Register (SCITD) [offset = 38h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 29-27. Transmit Data Buffer Register (SCITD) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                    |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                         |
| 7-0  | TD       | 0-FFh | Transmit data. This bit is effective in SCI-compatible mode only. Data to be transmitted is written to the SCITD register. The transfer of data from this register to the transmit shift register SCITXSHF sets the TXRDY flag, which indicates that SCITD is ready to be loaded with another byte of data.<br><b>Note: If TX INT ENA is set, this data transfer also causes an interrupt.</b> |

**NOTE:** Data written to the SCITD register that is fewer than eight bits long must be right justified, but it does not need to be padded with leading zeros.

### 29.13.14 SCI Pin I/O Control Register 0 (SCIPIO0)

[Figure 29-42](#) and [Table 29-28](#) illustrate this register.

**Figure 29-42. SCI Pin I/O Control Register 0 (SCIPIO0) [offset = 3Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 29-28. SCI Pin I/O Control Register 0 (SCIPIO0) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                                                                   |
|------|----------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0      | Read returns 0. Writes have no effect.                                                                                                                                                        |
| 2    | TX FUNC  | 0<br>1 | Transfer function. This bit is effective in LIN or SCI mode. This bit defines the function of pin LINTX.<br>LINTX is a general-purpose digital I/O pin.<br>LINTX is the SCI/LIN transmit pin. |
| 1    | RX FUNC  | 0<br>1 | Receive function. This bit is effective in LIN or SCI mode. This bit defines the function of pin LINRX.<br>LINRX is a general-purpose digital I/O pin.<br>LINRX is the SCI/LIN receive pin.   |
| 0    | Reserved | 0      | Read returns 0. Writes have no effect.                                                                                                                                                        |

### 29.13.15 SCI Pin I/O Control Register 1 (SCIPIO1)

Figure 29-43 and Table 29-29 illustrate this register.

**Figure 29-43. SCI Pin I/O Control Register 1 (SCIPIO1) [offset = 40h]**

|          |  |  |  |  |  |  |        |   |        |   |          |  |   |

Writes have no effect.                                                                                                                                                                                                                                                                                                                                     |
| 2    | TX DIR   | 0<br>1 | Transmit pin direction. This bit is effective in LIN or SCI mode. This bit determines the data direction on the LINTX pin if it is configured with general-purpose I/O functionality (TX FUNC = 0). See <a href="#">Table 29-30</a> for the LINTX pin control with this bit and others.<br>LINTX is a general-purpose input pin.<br>LINTX is a general-purpose output pin. |
| 1    | RX DIR   | 0<br>1 | Receive pin direction. This bit is effective in LIN or SCI mode. This bit determines the data direction on the LINRX pin if it is configured with general-purpose I/O functionality (RX FUNC = 0). See <a href="#">Table 29-31</a> for the LINRX pin control with this bit and others.<br>LINRX is a general-purpose input pin.<br>LINRX is a general-purpose output pin.  |
| 0    | Reserved | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                     |

**Table 29-30. LINTX Pin Control**

| Function                     | TX IN <sup>(1)</sup> | TX OUT | TX FUNC | TX DIR |
|------------------------------|----------------------|--------|---------|--------|
| LINTX                        | X                    | X      | 1       | X      |
| General purpose input        | X                    | X      | 0       | 0      |
| General purpose output, high | X                    | 1      | 0       | 1      |
| General purpose output, low  | X                    | 0      | 0       | 1      |

<sup>(1)</sup> TX IN is a read-only bit. Its value always reflects the level of the SCITX pin.

**Table 29-31. LINRX Pin Control**

| Function                     | RX IN <sup>(1)</sup> | RX OUT | RX FUNC | RX DIR |
|------------------------------|----------------------|--------|---------|--------|
| LINRX                        | X                    | X      | 1       | X      |
| General purpose input        | X                    | X      | 0       | 0      |
| General purpose output, high | X                    | 1      | 0       | 1      |
| General purpose output, low  | X                    | 0      | 0       | 1      |

<sup>(1)</sup> RX IN is a read-only bit. Its value always reflects the level of the SCIRX pin.

### 29.13.16 SCI Pin I/O Control Register 2 (SCIPIO2)

Figure 29-44 and Table 29-32 illustrate this register.

**Figure 29-44. SCI Pin I/O Control Register 2 (SCIPIO2) [offset = 44h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; -x = Indeterminate

**Table 29-32. SCI Pin I/O Control Register 2 (SCIPIO2) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                            |

Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 2    | TX SET   | 0<br>1 | Transmit pin set. This bit is effective in LIN or SCI mode. This bit sets the logic to be output on pin LINTX if the following conditions are met: <ul style="list-style-type: none"> <li>TX FUNC = 0 (LINTX pin is a general-purpose I/O.)</li> <li>TX DIR = 1 (LINTX pin is a general-purpose output.)</li> </ul> See Table 29-30 for an explanation of this bit's effect in combination with other bits. <p><i>Read:</i> The output on LINTX is at logic low (0).<br/> <i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read and write:</i> The output on LINTX is at logic high (1).</p>   |
| 1    | RX SET   | 0<br>1 | Receive pin set. This bit is effective in LIN or SCI mode. This bit sets the data to be output on pin LINRX if the following conditions are met: <ul style="list-style-type: none"> <li>RX FUNC = 0 (LINRX pin is a general-purpose I/O.)</li> <li>RX DIR = 1 (LINRX pin is a general-purpose output.)</li> </ul> See Table 29-31 for an explanation of this bit's effect in combination with the other bits. <p><i>Read:</i> The output on LINRX is at logic low (0).<br/> <i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read and write:</i> The output on LINRX is at logic high (1).</p> |
| 0    | Reserved | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 29.13.19 SCI Pin I/O Control Register 5 (SCIPIO5)

Figure 29-47 and Table 29-35 illustrate this register.

**Figure 29-47. SCI Pin I/O Control Register 5 (SCIPIO5) [offset = 50h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 29-35. SCI Pin I/O Control Register 5 (SCIPIO5) Field Descriptions**

| Bit  | Field    | Value                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------|----------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0                         | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 2    | TX CLR   | <div>0</div> <div>1</div> | <p>Transmit pin clear. This bit is effective in LIN or SCI mode. This bit clears the logic to be output on pin LINTX if the following conditions are met:</p> <ul style="list-style-type: none"> <li>TX FUNC = 0 (LINTX pin is a general-purpose I/O.)</li> <li>TX DIR = 1 (LINTX pin is a general-purpose output.)</li> </ul> <p><b>0</b><br/>Read: The output on LINTX is at logic low (0).<br/>Write: Writing a 0 to this bit has no effect.</p> <p><b>1</b><br/>Read: The output on LINTX is at logic high (1).<br/>Write: The output on LINTX is at logic low (0).</p> |
| 1    | RX CLR   | <div>0</div> <div>1</div> | <p>Receive pin clear. This bit is effective in LIN or SCI mode. This bit clears the logic to be output on pin LINRX if the following conditions are met:</p> <ul style="list-style-type: none"> <li>RX FUNC = 0 (LINRX pin is a general-purpose I/O.)</li> <li>RX DIR = 1 (LINRX pin is a general-purpose output.)</li> </ul> <p><b>0</b><br/>Read: The output on LINRX is at logic low (0).<br/>Write: Writing a 0 to this bit has no effect.</p> <p><b>1</b><br/>Read: The output on LINRX is at logic high (1).<br/>Write: The output on LINRX is at logic low (0).</p>  |
| 0    | Reserved | 0                         | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### 29.13.20 SCI Pin I/O Control Register 6 (SCIPIO6)

Figure 29-48 and Table 29-36 illustrate this register.

**Table 29-42. LIN Mask Register (LINMASK) Field Descriptions**

| Bit   | Field      | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | Reserved   | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 23-16 | RX ID MASK | 0-FFh | Receive ID mask. These bits are effective in LIN mode only. This 8-bit mask is used for filtering an incoming ID message and comparing it to the ID-byte. A compare match of the received ID with the RX ID mask will set the ID RX flag and trigger an ID interrupt if enabled (SET ID INT in SCISSETINT). A 0 bit in the mask indicates that bit is compared to the ID-byte. A 1 bit in the mask indicates that bit is filtered and therefore is not used in the compare.   |
| 15-8  | Reserved   | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 7-0   | TX ID MASK | 0-FFh | Transmit ID mask. These bits are effective in LIN mode only. This 8-bit mask is used for filtering an incoming ID message and comparing it to the ID-byte. A compare match of the received ID with the TX ID mask will set the ID TX flag and trigger an ID interrupt if enabled (SET ID INT in SCISSETINT). A 0 bit in the mask indicates that bit is compared to the ID-byte. A 1 bit in the mask indicates that bit is filtered and therefore is not used for the compare. |

### 29.13.27 LIN Identification Register (LINID)

Figure 29-55 and Table 29-43 illustrate this register.

**Figure 29-55. LIN Identification Register (LINID) [offset = 70h]**

|                   |  |    |    |             |    |

LEGEND: R/W = Read/Write; R = Read only; WL = Write in LIN mode only; -n = value after reset

**Table 29-43. LIN Identification Register (LINID) Field Descriptions**

| Bit   | Field             | Value | Description                                                                                                                                                                                                                                                                                                                       |
|-------|-------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | Reserved          | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                            |
| 23-16 | RECEIVED ID       | 0-FFh | Received identification. These bits are effective in LIN mode only. This byte contains the current message identifier. During header reception the received ID is copied from the SCIRXSHF register to this byte if there is no ID-parity error and there has been an RX/TX match.                                                |
| 15-8  | ID-SLAVETASK BYTE | 0-FFh | ID-SlaveTask Byte. These bits are effective in LIN mode only. This field contains the identifier to which the received ID of an incoming header will be compared to decide whether a receive response, a transmit response, or no action needs to be performed by the LIN node when a header with that particular ID is received. |
| 7-0   | ID BYTE           | 0-FFh | ID byte. This field is effective in LIN mode only. This byte is the LIN mode message ID. On a master node, a write to this register by the CPU initiates a header transmission. For a slave task, this byte is used for message filtering when HGENCTRL = 0.                                                                      |

**NOTE:** For software compatibility with future LIN modules the HGEN CTRL bit must be set to 1, the RX ID MASK must be set to FFh and the TX ID MASK must be set to FFh.

### 29.13.28 LIN Transmit Buffer 0 Register(LINTD0)

Figure 29-56 and Table 29-44 illustrate this register.

**Figure 29-56. LIN Transmit Buffer 0 Register (LINTD0) [offset = 74h]**

**Table 29-45. LIN Transmit Buffer 1 Register (LINTD1) Field Descriptions**

| Bit   | Field | Value | Description                                                                                                                                                                                                        |
|-------|-------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | TD4   | 0-FFh | 8-Bit transmit buffer 4. Byte 4 to be transmitted is written into this register and then copied to SCITXSHF for transmission.<br><b>Note: TD&lt;x-1&gt; is equivalent to data byte &lt;x&gt; of the LIN frame.</b> |
| 23-16 | TD5   | 0-FFh | 8-Bit transmit buffer 5. Byte 5 to be transmitted is written into this register and then copied to SCITXSHF for transmission.                                                                                      |
| 15-8  | TD6   | 0-FFh | 8-Bit transmit buffer 6. Byte 6 to be transmitted is written into this register and then copied to SCITXSHF for transmission.                                                                                      |
| 7-0   | TD7   | 0-FFh | 8-Bit transmit buffer 7. Byte 7 to be transmitted is written into this register and then copied to SCITXSHF for transmission.                                                                                      |

### 29.13.30 Maximum Baud Rate Selection Register (MBRS)

Figure 29-58 and Table 29-46 illustrate this register.

**Figure 29-58. Maximum Baud Rate Selection Register (MBRS) [offset = 7Ch]**

LEGEND: R/W = Read/Write; R = Read only; WL = Write in LIN mode only; -n = value after reset

**Table 29-46. Maximum Baud Rate Selection Register (MBRS) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|----------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-13 | Reserved | 0       | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 12-0  | MBR      | 0-1FFFh | <p>Maximum baud rate prescaler. This bit is effective in LIN mode only. This 13-bit prescaler is used during the synchronization phase (see <a href="#">Section 29.7.5.2</a>) of a slave module if the ADAPT bit is set. In this way, a SCI/LIN slave using an automatic or select bit rate modes detects any LIN bus legal rate automatically.</p> <p>The MBR value should be programmed to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise, a 0x00 data byte could mistakenly be detected as a sync break.</p> <p>The default value for a 70Mhz VCLK is 0xDAC.</p> <p>This MBR prescaler is used by the wake-up and idle time counters for a constant expiration time relative to a 20 kHz rate.</p> <p style="text-align: center;"><math>MBR = \frac{0.9 \times VCLK}{maxbaudrate}</math></p> |

### 29.13.31 Input/Output Error Enable (IODFTCTRL) Register

All the bits in the IODFTCTRL register are used in IODFT (I/O design for test) mode only. [Figure 29-59](#) and [Table 29-47](#) illustrate this register. After the basic SCI/LIN module configuration, enable the required Error mode to be created followed by IODFT Key enable.

**Figure 29-59. Input/Output Error Enable Register (IODFTCTRL) [offset = 90h]**

LEGEND: R/W = Read/Write; R = Read only; WL = Write in LIN mode only; WC = Write in SCI-compatible mode only; WP = Write in privilege mode only; -n = value after reset

- NOTE:**
- 1) All the bits are used in IODFT mode only.
  - 2) Each IODFT are expected to be checked individually.
  - 3) ISFE Error will not be Flagged during IODFT mode.

**Table 29-47. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions**

| Bit | Field    | Value | Description                                                                                                                                        |
|-----|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 31  | BEN      | 0     | Bit error enable. This bit is effective in LIN mode only. This bit is used to create a bit error. No bit error is created.                         |
|     |          | 1     | The bit received is ORed with 1 and passed to the bit monitor circuitry.                                                                           |
| 30  | PBEN     | 0     | Physical bus error enable. This bit is effective in LIN mode only. This bit is used to create a physical bus error. No error is created.           |
|     |          | 1     | The bit received during synch break field transmission is ORed with 1 and passed to the bit monitor circuitry.                                     |
| 29  | CEN      | 0     | Checksum error enable. This bit is effective in LIN mode only. This bit is used to create a checksum error. No error is created.                   |
|     |          | 1     | The polarity of the CTYPE (checksum type) in the receive checksum calculator is changed so that a checksum error is occurred.                      |
| 28  | ISFE     | 0     | Inconsistent synch field (ISF) error enable. This bit is effective in LIN mode only. This bit is used to create an ISF error. No error is created. |
|     |          | 1     | The bit widths in the synch field are varied so that the ISF check fails and the error flag is set.                                                |
| 27  | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                             |
| 26  | FEN      | 0     | Frame error enable. This bit is used to create a frame error. No error is created.                                                                 |
|     |          | 1     | The stop bit received is ANDed with 0 and passed to the stop bit check circuitry.                                                                  |

**Table 29-47. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions (continued)**

| Bit   | Field           | Value                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|-----------------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 25    | PEN             | 0<br>1                                      | Parity error enable. This bit is effective in SCI-compatible mode only. This bit is used to create a parity error.<br>No parity error occurs.<br>The parity bit received is toggled so that a parity error occurs.                                                                                                                                                                                                                                                                           |
| 24    | BRKD TENA       | 0<br>1                                      | Break detect error enable. This bit is effective in SCI-compatible mode only. This bit is used to create a BRKDT error.<br>No error is created.<br>The stop bit of the frame is ANDed with 0 and passed to the RSM so that a frame error occurs. Then the RX pin is forced to continuous low for 10 T <sub>BITS</sub> so that a BRKDT error occurs.                                                                                                                                          |
| 32-21 | Reserved        | 0                                           | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 20-19 | PIN SAMPLE MASK | 0<br>1h<br>2h<br>3h                         | Pin sample mask. These bits define the sample number at which the TX pin value that is being transmitted will be inverted to verify the receive pin samples majority detection circuitry.<br><b>Note: In IODFT mode testing for pin_sample mask must be done with prescaler P programmed greater than 2 (P &gt; 2).</b><br>No mask is used.<br>Invert the TX Pin value at TBIT_CENTER.<br>Invert the TX Pin value at TBIT_CENTER + SCLK.<br>Invert the TX Pin value at TBIT_CENTER + 2 SCLK. |
| 18-16 | TX SHIFT        | 0<br>1h<br>2h<br>3h<br>4h<br>5h<br>6h<br>7h | Transmit shift. These bits define the amount by which the value on TX pin is delayed so that the value on the RX pin is asynchronous. This feature is not applicable to the start bit.<br>No delay occurs.<br>The value is delayed by 1 SCLK.<br>The value is delayed by 2 SCLK.<br>The value is delayed by 3 SCLK.<br>The value is delayed by 4 SCLK.<br>The value is delayed by 5 SCLK.<br>The value is delayed by 6 SCLK.<br>The value is delayed by 7 SCLK.                              |
| 15-12 | Reserved        | 0                                           | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 11-8  | IODFTENA        | Ah<br>All Others                            | IODFT enable key. This bit defines whether the I/O buffers for the transmit or the receive pin are included in the communication path (in analog loopback mode).<br>Analog loopback through the transmit pin is enabled.<br>Analog loopback through the receive pin is enabled.                                                                                                                              |

## 29.14 GPIO Functionality

The following sections apply to all device pins that can be configured as functional or general-purpose I/O pins.

### 29.14.1 GPIO Functionality

Figure 29-60 illustrates the GPIO functionality.

**Figure 29-60. GPIO Functionality**

### 29.14.2 Under Reset

The following apply if a device is under reset:

- Pull control. The reset pull control on the pins is enabled or disabled depending on a device-specific option. This feature is configurable for each module separately.
- Input buffer. The input buffer is enabled.
- Output buffer. The output buffer is disabled.

### 29.14.3 Out of Reset

The following apply if the device is out of reset:

- Pull control. The pull control is enabled by clearing the PD (pull control disable) bit in the SCIPIO7 register (Section 29.13.21). In this case, if the PSL (pull select) bit in the SCIPIO8 register (Section 29.13.22) is set, the pin will have a pull-up. If the PSL bit is cleared, the pin will have a pull-down. If the PD bit is set in the control register, there is no pull-up or pull-down on the pin.
- Input buffer. The input buffer is permanently enabled in this device.

---

**NOTE:** The pull-disable logic depends on the pin direction. It is independent of whether the device is in I/O or functional mode. If the pin is configured as output or transmit, then the pulls are disabled automatically.

---

- Output buffer. A pin can be driven as an output pin if the TX DIR bit is set in the pin direction control register (SCIPIO1; Section 29.13.15) AND the open-drain feature is not enabled in the SCIPIO6 register (Section 29.13.20).

### 29.14.4 Open-Drain Feature Enabled on a Pin

The following apply if the open-drain feature is enabled on a pin:

- The output buffer is enabled if a low signal is being driven on to the pin.
- The output buffer is disabled (the direction control signal DIR is internally forced low) if a high signal is being driven on to the pin.

---

**NOTE:** The open-drain feature is available only in I/O mode (SCIPIO0; Section 29.13.14).

---

### 29.14.5 Summary

The behavior of the input buffer, output buffer, and the pull control is summarized in Table 29-48.

**Table 29-48. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins <sup>(1)</sup>**

| Device under Reset? | Pin Direction (DIR) <sup>(2)</sup> | Pull Disable (PULDIS) <sup>(3)</sup> | Pull Select (PULSEL) <sup>(4)</sup> | Pull Control                | Output Buffer | Input Buffer |
|---------------------|------------------------------------|--------------------------------------|-------------------------------------|-----------------------------|---------------|--------------|
| Yes                 | X                                  | X                                    | X                                   | Device- and module-specific | Disabled      | Enabled      |
| No                  | 0                                  | 0                                    | 0                                   | Pull down                   | Disabled      | Enabled      |
| No                  | 0                                  | 0                                    | 1                                   | Pull up                     | Disabled      | Enabled      |
| No                  | 0                                  | 1                                    | 0                                   | Disabled                    | Disabled      | Enabled      |

## 30.1 Introduction

The SCI module is a universal asynchronous receiver-transmitter that implements the standard nonreturn to zero format. The SCI can be used to communicate, for example, through an RS-232 port or over a K-line.

### 30.1.1 SCI Features

The following are the features of the SCI module:

- Standard universal asynchronous receiver-transmitter (UART) communication
- Supports full- or half-duplex operation
- Standard nonreturn to zero (NRZ) format
- Double-buffered receive and transmit functions
- Supports two individually enabled interrupt lines: level 0 and level 1
- Configurable frame format of 3 to 13 bits per character based on the following:
  - Data word length programmable from one to eight bits
  - Additional address bit in address-bit mode
  - Parity programmable for zero or one parity bit, odd or even parity
  - Stop programmable for one or two stop bits
- Asynchronous or isosynchronous communication modes with no CLK pin
- Two multiprocessor communication formats allow communication between more than two devices
- Sleep mode is available to free CPU resources during multiprocessor communication and then wake up to receive an incoming message
- The 24-bit programmable baud rate supports  $2^{24}$  different baud rates provide high accuracy baud rate selection
- Capability to use Direct Memory Access (DMA) for transmit and receive data
- Four error flags and Five status flags provide detailed information regarding SCI events
- Two external pins: SCIRX and SCITX

---

**NOTE:** SCI module does not support UART Hardware Flow Control. This feature can be implemented in Software using a General Purpose I/O pin.

---

### 30.1.2 Block Diagram

Three Major components of the SCI Module are:

- Transmitter
- Baud Clock Generator
- Receiver

**Transmitter (TX)** contains two major registers to perform double buffering:

- The transmitter data buffer register (SCITD) contains data loaded by the CPU to be transferred to the shift register for transmission.
- The transmitter shift register (SCITXSHF) loads data from the data buffer (SCITD) and shifts data onto the SCITX pin, one bit at a time.

#### Baud Clock Generator

- A programmable baud generator produces a baud clock scaled from VBUSP CLK.

**Receiver (RX)** contains two major registers to perform double buffering:

- The receiver shift register (SCIRXSHF) shifts data in from the SCIRX pin one bit at a time and transfers completed data into the receive data buffer.
- The receiver data buffer register (SCIRD) contains received data transferred from the receiver shift register

The SCI receiver and transmitter are double-buffered, and each has its own separate enable and interrupt bits. The receiver and transmitter may each be operated independently or simultaneously in full duplex mode.

To ensure data integrity, the SCI checks the data it receives for breaks, parity, overrun, and framing errors. The bit rate (baud) is programmable to over 16 million different rates through a 24-bit baud-select register. Figure 30-1 shows the detailed SCI block diagram.

**Figure 30-1. Detailed SCI Block Diagram**

## 30.2 SCI Communication Formats

The SCI module can be configured to meet the requirements of many applications. Because communication formats vary depending on the specific application, many attributes of the SCI are user configurable. The list below describes these configuration options:

- SCI Frame format
- SCI Timing modes
- SCI Baud rate
- SCI Multiprocessor modes

### 30.2.1 SCI Frame Formats

The SCI uses a programmable frame format. All frames consist of the following:

- One start bit
- One to eight data bits
- Zero or one address bit
- Zero or one parity bit
- One or two stop bits

The frame format for both the transmitter and receiver is programmable through the bits in the SCIGCR1 register. Both receive and transmit data is in nonreturn to zero (NRZ) format, which means that the transmit and receive lines are at logic high when idle. Each frame transmission begins with a start bit, in which the transmitter pulls the SCI line low (logic low). Following the start bit, the frame data is sent and received least significant bit first (LSB).

An address bit is present in each frame if the SCI is configured to be in address-bit mode but is not present in any frame if the SCI is configured for idle-line mode. The format of frames with and without the address bit is illustrated in [Figure 30-2](#).

A parity bit is present in every frame when the PARITY ENA bit is set. The value of the parity bit depends on the number of one bits in the frame and whether odd or even parity has been selected via the PARITY ENA bit. Both examples in [Figure 30-2](#) have parity enabled.

All frames include one stop bit, which is always a high level. This high level at the end of each frame is used to indicate the end of a frame to ensure synchronization between communicating devices. Two stop bits are transmitted if the STOP bit in SCIGCR1 register is set. The examples shown in [Figure 30-2](#) use one stop bit per frame.

**Figure 30-2. Typical SCI Data Frame Formats**

### 30.2.2 SCI Timing Mode

The SCI can be configured to use asynchronous or isosynchronous timing using TIMING MODE bit in SCIGCR1 register.

### 30.2.2.1 Asynchronous Timing Mode

The asynchronous timing mode uses only the receive and transmit data lines to interface with devices using the standard universal asynchronous receiver-transmitter (UART) protocol.

In the asynchronous timing mode, each bit in a frame has a duration of 16 SCI baud clock periods. Each bit therefore consists of 16 samples (one for each clock period). When the SCI is using asynchronous mode, the baud rates of all communicating devices must match as closely as possible. Receive errors result from devices communicating at different baud rates.

With the receiver in the asynchronous timing mode, the SCI detects a valid start bit if the first four samples after a falling edge on the SCIRX pin are of logic level 0. As soon as a falling edge is detected on SCIRX, the SCI assumes that a frame is being received and synchronizes itself to the bus.

To prevent interpreting noise as Start bit SCI expects SCIRX line to be low for at least four contiguous SCI baud clock periods to detect a valid start bit. The bus is considered idle if this condition is not met. When a valid start bit is detected, the SCI determines the value of each bit by sampling the SCIRX line value during the seventh, eighth, and ninth SCI baud clock periods. A majority vote of these three samples is used to determine the value stored in the SCI receiver shift register. By sampling in the middle of the bit, the SCI reduces errors caused by propagation delays and rise and fall times and data line noises.

Figure 30-3 illustrates how the receiver samples a start bit and a data bit in asynchronous timing mode.

The transmitter transmits each bit for a duration of 16 SCI baud clock periods. During the first clock period for a bit, the transmitter shifts the value of that bit onto the SCITX pin. The transmitter then holds the current bit value on SCITX for 16 SCI baud clock periods.

**Figure 30-3. Asynchronous Communication Bit Timing**

### 30.2.2.2 Isosynchronous Timing Mode

In isosynchronous timing mode, each bit in a frame has a duration of exactly 1 baud clock period and therefore consists of a single sample. With this timing configuration, the transmitter and receiver are required to make use of the SCICLK pin to synchronize communication with other SCI. **This mode is not fully supported on this device because SCICLK pin is not available.**

### 30.2.3 SCI Baud Rate

The SCI has an internally generated serial clock determined by the peripheral VCLK and the prescalers BAUD. The SCI uses the 24-bit integer prescaler BAUD value of BRSR register to select the required baud rates.

In asynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$\text{Asynchronous baud value} = \frac{\text{VBUSPCLK Frequency}}{16 \text{ BAUD} + 1}$$

For BAUD = 0,

$$\text{Asynchronous baud value} = \frac{\text{VCLK Frequency}}{32} \quad (60)$$

In isosynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$\text{Isosynchronous baud value} = \frac{\text{VBUSPCLK Frequency}}{\text{BAUD} + 1}$$

For BAUD = 0,

$$\text{Isosynchronous baud value} = \frac{\text{VCLK Frequency}}{32} \quad (61)$$

### 30.2.4 SCI Multiprocessor Communication Modes

In some applications, the SCI may be connected to more than one serial communication device. In such a multiprocessor configuration, several frames of data may be sent to all connected devices or to an individual device. In the case of data sent to an individual device, the receiving devices must determine when they are being addressed. When a message is not intended for them, the devices can ignore the following data. When only two devices make up the SCI network, addressing is not needed, so multiprocessor communication schemes are not required.

SCI supports two multiprocessor Communication Modes which can be selected using COMM MODE bit:

- Idle-Line Mode
- Address Bit Mode

When the SCI is not used in a multiprocessor environment, software can consider all frames as data frames. In this case, the only distinction between the idle-line and address-bit modes is the presence of an extra bit (the address bit) in each frame sent with the address-bit protocol.

The SCI allows full-duplex communication where data can be sent and received via the transmit and receive pins simultaneously. However, the protocol used by the SCI assumes that only one device transmits data on the same bus line at any one time. No arbitration is done by the SCI.

---

**NOTE: Avoid Transmitting Simultaneously on the Same Serial Bus**

The system designer must ensure that devices connected to the same serial bus line do not attempt to transmit simultaneously. If two devices are transmitting different data, the resulting bus conflict could damage the device..

---

#### 30.2.4.1 Idle-Line Multiprocessor Modes

In idle-line multiprocessor mode, a frame that is preceded by an idle period (10 or more idle bits) is an address frame. A frame that is preceded by fewer than 10 idle bits is a data frame. [Figure 30-4](#) illustrates the format of several blocks and frames with idle-line mode.

There are two ways to transmit an address frame using idle-line mode:

**Method 1:** In software, deliberately leave an idle period between the transmission of the last data frame of the previous block and the address frame of the new block.

**Method 2:** Configure the SCI to automatically send an idle period between the last data frame of the previous block and the address frame of the new block.

Although Method 1 is only accomplished by a delay loop in software, Method 2 can be implemented by using the transmit buffer and the TXWAKE bit in the following manner:

Step1 : Write a 1 to the TXWAKE bit.

Step2 : Write a dummy data value to the SCITD register. This triggers the SCI to begin the idle period as soon as the transmitter shift register is empty.

Step3 : Wait for the SCI to clear the TXWAKE flag.

Step4 : Write the address value to SCITD.

As indicated by Step 3, software should wait for the SCI to clear the TXWAKE bit. However, the SCI clears the TXWAKE bit at the same time it sets TXRDY (that is, transfers data from SCITD into SCITXSHF). Therefore, if the TX INT ENA bit is set, the transfer of data from SCITD to SCITXSHF causes an interrupt to be generated at the same time that the SCI clears the TXWAKE bit. If this interrupt method is used, software is not required to poll the TXWAKE bit waiting for the SCI to clear it.

When idle-line multiprocessor communications are used, software must ensure that the idle time exceeds 10 bit periods before addresses (using one of the methods mentioned above), and software must also ensure that data frames are written to the transmitter quickly enough to be sent without a delay of 10 bit periods between frames. Failure to comply with these conditions will result in data interpretation errors by other devices receiving the transmission.

**Figure 30-4. Idle-Line Multiprocessor Communication Format**

### 30.2.4.2 Address-Bit Multiprocessor Mode

In the address-bit protocol, each frame has an extra bit immediately following the data field called an address bit. A frame with the address bit set to 1 is an address frame; a frame with the address bit set to 0 is a data frame. The idle period timing is irrelevant in this mode. Figure 30-5 illustrates the format of several blocks and frames with the address-bit mode.

When address-bit mode is used, the value of the TXWAKE bit is the value sent as the address bit. To send an address frame, software must set the TXWAKE bit. This bit is cleared as the contents of the SCITD are shifted from the TXWAKE register so that all frames sent are data except when the TXWAKE bit is written as a 1.

No dummy write to SCITD is required before an address frame is sent in address-bit mode. The first byte written to SCITD after the TXWAKE bit is written to 1 is transmitted with the address bit set when address-bit mode is used.

**Figure 30-5. Address-Bit Multiprocessor Communication Format**

### 30.3 SCI Interrupts

The SCI module has two interrupt lines, level 0 and level 1, to the vectored interrupt manager (VIM) module (see [Figure 30-6](#)). Two offset registers SCIINTVECT0 and SCIINTVECT1 determine which flag triggered the interrupt according to the respective priority encoders. Each interrupt condition has a bit to enable/disable the interrupt in the SCISSETINT and SCICLRINT registers respectively.

Each interrupt also has a bit that can be set as interrupt level 0 (INT0) or as interrupt level 1 (INT1). By default, interrupts are in interrupt level 0. SCISSETINTLVL sets a given interrupt to level1. SCICLEARINTLVL resets a given interrupt level to the default level 0.

The interrupt vector registers SCIINTVECT0 and SCIINTVECT1 return the vector of the pending interrupt line INT0 or INT1. If more than one interrupt is pending, the interrupt vector register holds the highest priority interrupt.

**Figure 30-6. General Interrupt Scheme**

**Figure 30-7. Interrupt Generation for Given Flags**

### 30.3.1 Transmit Interrupt

To use transmit interrupt functionality, SET TX INT bit must be enabled and SET TX DMA bit must be cleared. The transmit ready (TXRDY) flag is set when the SCI transfers the contents of SCITD to the shift register, SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty. If the SET TX INT bit is set, then a transmit interrupt is generated when the TXRDY flag goes high. Transmit Interrupt is not generated immediately after setting the SET TX INT bit unlike transmit DMA request. Transmit Interrupt is generated only after the first transfer from SCITD to SCITXSHF, that is first data has to be written to SCITD by the User before any interrupt gets generated. To transmit further data the user can write data to SCITD in the transmit Interrupt service routine.

Writing data to the SCITD register clears the TXRDY bit. When this data has been moved to the SCITXSHF register, the TXRDY bit is set again. The interrupt request can be suspended by setting the CLR TX INT bit; however, when the SET TX INT bit is again set to 1, the TXRDY interrupt is asserted again. The transmit interrupt request can be eliminated until the next series of values is written to SCITD, by disabling the transmitter via the TXENA bit, by a software reset SWnRST, or by a device hardware reset.

### 30.3.2 Receive Interrupt

The receive ready (RXRDY) flag is set when the SCI transfers newly received data from SCIRXSHF to SCIRD. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive interrupts are enabled by the SET RX INT bit. If the SET RX INT is set when the SCI sets the RXRDY flag, then a receive interrupt is generated. The received data can be read in the Interrupt Service routine.

On a device with both SCI and a DMA controller, the bits SET RX DMA ALL and SET RX DMA must be cleared to select interrupt functionality.

### 30.3.3 WakeUp Interrupt

SCI sets the WAKEUP flag if bus activity on the RX line either prevents power-down mode from being entered, or RX line activity causes an exit from power-down mode. If enabled (SET WAKEUP INT), wakeup interrupt is triggered once WAKEUP flag is set.

### 30.3.4 Error Interrupts

The following error detection features are supported with Interrupt by the SCI module:

- Parity errors (PE)
- Frame errors (FE)
- Break Detect errors (BRKDT)
- Overrun errors (OE)

If all of these errors (PE, FE, BRKDT, OE) are flagged, an interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame. Each of these flags is located in the receiver status (SCIFLR) register. Further details on these flags are explained in SCIFLR register description.

The SCI module supports following 7 interrupts as seen in [Table 30-1](#).

**Table 30-1. SCI Interrupts**

| Offset <sup>(1)</sup> | Interrupt          |
|-----------------------|--------------------|
| 0                     | Reserved           |
| 1                     | Wakeup             |
| 2                     | Reserved           |
| 3                     | Parity error       |
| 4                     | Reserved           |
| 5                     | Reserved           |
| 6                     | Frame error        |
| 7                     | Break detect error |
| 8                     | Reserved           |
| 9                     | Overrun error      |
| 10                    | Reserved           |
| 11                    | Receive            |
| 12                    | Transmit           |
| 13 - 15               | Reserved           |

<sup>(1)</sup> Offset 1 is the highest priority. Offset 16 is the lowest priority.

## 30.4 SCI DMA Interface

DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI module. Refer to the DMA module chapter for DMA module configurations.

### 30.4.1 Receive DMA Requests

This DMA functionality is enabled/disabled by the CPU using the SET RX DMA/CLR RX DMA bits, respectively.

The receiver DMA request is set when a frame is received successfully and DMA functionality has been previously enabled. The RXRDY flag is set when the SCI transfers newly received data from the SCIRXSHF register to the SCIRD buffer. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive DMA requests are enabled by the SET RX INT bit.

Parity, overrun, break detect, wake-up, and framing errors generate an error interrupt request immediately upon detection, if enabled, even if the device is in the process of a DMA data transfer. The DMA transfer is postponed until the error interrupt is served. The error interrupt can delete this particular DMA request by reading the receive buffer.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames. This is controlled by an extra select bit SET RX DMA ALL.

If the SET RX DMA ALL bit is set and the SET RX DMA bit is set when the SCI sets the RXRDY flag, then a receive DMA request is generated for address and data frames.

If the SET RX DMA ALL bit is cleared and the SET RX DMA bit is set when the SCI sets the RXRDY flag upon receipt of a data frame, then a receive DMA request is generated. Receive interrupt requests are generated for address frames.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received. [Table 30-2](#) specifies the bit values for DMA requests in multiprocessor modes.

**Table 30-2. DMA and Interrupt Requests in Multiprocessor Modes**

| SET RX INT | SET RX DMA | SET RX DMA ALL | ADDR FRAME INT | ADDR FRAME DMA | DATA FRAME INT | DATA FRAME DMA |
|------------|------------|----------------|----------------|----------------|----------------|----------------|
| 0          | 0          | x              | N              | N              | N              | N              |
| 0          | 1          | 0              | Y              | N              | N              | Y              |
| 0          | 1          | 1              | N              | Y              | N              | Y              |
| 1          | 0          | x              | Y              | N              | Y              | N              |
| 1          | 1          | 0              | Y              | N              | Y              | Y              |
| 1          | 1          | 1              | Y              | Y              | Y              | Y              |

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames or DMA requests for both. This is controlled by the SET RX DMA ALL bit.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received.

### 30.4.2 Transmit DMA Requests

DMA functionality is enabled/disabled by the CPU with SET TX DMA/CLR TX DMA bits, respectively.

The TXRDY flag is set when the SCI transfers the contents of SCITD to SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty.

Transmit DMA requests are enabled by the setting SET TX DMA and SET TX INT bits.

If the SET TX DMA bit is set, then a TX DMA request is sent to the DMA when data is written to SCITD and TXRDY is set.

The DMA will write the first byte to the transmit buffer.

## 30.5 SCI Configurations

Before the SCI sends or receives data, its registers should be properly configured. Upon power-up or a system-level reset, each bit in the SCI registers is set to a default state. The registers are writable only after the RESET bit is set to 1. Of particular importance is the SWnRST bit. This active-low bit is initialized to 0 and keeps the SCI in a reset state until it is programmed to 1. Therefore, all SCI configuration should be completed before a 1 (one) is written to the SWnRST bit.

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as SWnRST is held low the entire time that the SCI is being configured, the order in which the registers are programmed is not important.

- Enable SCI by setting RESET bit.
- Clear SWnRST to 0 before configuring the SCI.
- Select the desired frame format by programming SCIGCR1.
- Configure the SCIRX and SCITX pins for SCI functionality by setting the RX FUNC and TX FUNC bit.
- Select the baud rate to be used for communication by programming BRSR.
- Select internal clock by programming the CLOCK bit.
- Set the CONT bit to make SCI not to halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set LOOP BACK bit to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Select the receiver enable RXENA bit if data is to be received.
- Select the transmit enable TXENA bit if data is to be transmitted.
- Set SWnRST to 1 after the SCI is configured.
- Perform Receive or Transmit data (see [Section 30.5.1](#) / [Section 30.5.2](#)).

### 30.5.1 Receiving Data

The SCI receiver is enabled to receive messages if the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the SCIRX pin functions as a general purpose I/O pin rather than as an SCI function pin. After a valid idle period is detected, data is automatically received as it arrives on the SCIRX pin.

SCI sets the RXRDY bit when it transfers newly received data from SCIRXSHF to SCIRD. The SCI clears the RXRDY bit after the new data in SCIRD has been read. Also, as data is transferred from SCIRXSHF to SCIRD, the SCI sets FE, OE, or PE if any of these error conditions were detected in the received data. These error conditions are supported with configurable Interrupt capability. The wake-up and break-detect status bits are also set if one of these errors occurs, but they do not necessarily occur at the same time that new data is being loaded into SCIRD.

User can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for RXRDY bit and read the data from SCIRD register once RXRDY is set high. CPU is unnecessarily overloaded by selecting Polling mode. To avoid this user can use either Interrupt or DMA method. To use interrupt method SET RX INT bit should be set and to use DMA SET RX DMA bit should be set. Either an Interrupt or a DMA request is generated the moment RXRDY is set.

### 30.5.2 Transmitting Data

The SCI transmitter is enabled if the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the SCITX pin functions as a general purpose I/O pin rather than as an SCI function pin. Any value written to the SCITD before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

SCI waits for data to be written to SCITD, transfers it to SCITXSHF, and transmits it. The flags TXRDY and TX EMPTY indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to SCITD, the TXRDY bit is set. Additionally, if both SCITD and SCITXSHF are empty, then the TX EMPTY bit is also set.

User can transmit data by:

1. Polling Transmit Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for TXRDY bit to go high before writing the data to SCITD register. CPU is unnecessarily overloaded by doing this Polling method. To avoid this user can use either Interrupt or DMA method. To use interrupt method SET TX INT bit should be set and to use DMA SET TX DMA bit should be set. Either an Interrupt or a DMA request is generated the moment TXRDY is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and SCITD are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can be done by either disabling the transmit interrupt (CLR TX INT) / DMA request (CLR TX DMA bit) or by disabling the transmitter (clear TXENA bit).

---

**NOTE:** The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

---

## 30.6 SCI Low Power Mode

The SCI can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI. During global low-power mode, all clocks to the SCI are turned off so the module is completely inactive.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI internal logic and the module registers. Setting the POWERDOWN bit causes the SCI to enter local low-power mode and clearing the POWERDOWN bit causes SCI to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SCI for that particular access alone.

The wake-up interrupt is used to allow the SCI to exit low-power mode automatically when a low level is detected on the SCIRX pin and also this clears the POWERDOWN bit. If wake-up interrupt is disabled, then the SCI immediately enters low-power mode whenever it is requested and also any activity on the SCIRX pin does not cause the SCI to exit low-power mode.

---

**NOTE:** Enabling Local Low-Power Mode During Receive and Transmit

If the wake-up interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI immediately generates a wake-up interrupt to clear the powerdown bit and prevents the SCI from entering low-power mode and thus completes the current reception. Otherwise, if the wake-up interrupt is disabled, then the SCI completes the current reception and then enters the low-power mode.

---

### 30.6.1 Sleep Mode for Multiprocessor Communication

When the SCI receives data and transfers that data from SCIRXSHF to SCIRD, the RXRDY bit is set and if RX INT ENA is set, the SCI also generates an interrupt. The interrupt triggers the CPU to read the newly received frame before another one is received. In multiprocessor communication modes, this default behavior may be enhanced to provide selective indication of new data. When SCI receives an address frame that does not match its address, the device can ignore the data following this non-matching address until the next address frame by using sleep mode. Sleep mode can be used with both idle-line and address-bit multiprocessor modes.

If sleep mode is enabled by the SLEEP bit, then the SCI transfers data from SCIRXSHF to SCIRD only for address frames. Therefore, in sleep mode, all data frames are assembled in the SCIRXSHF register without being shifted into the SCIRD and without initiating a receive interrupt or DMA request. Upon reception of an address frame, the contents of the SCIRXSHF are moved into SCIRD, and the software must read SCIRD and determine if the SCI is being addressed by comparing the received address against the address previously set in the software and stored somewhere in memory (the SCI does not have hardware available for address comparison). If the SCI is being addressed, the software must clear the SLEEP bit so that the SCI will load SCIRD with the data of the data frames that follow the address frame.

When the SCI has been addressed and sleep mode has been disabled (in software) to allow the receipt of data, the SCI should check the RXWAKE bit (SCIFLR.12) to determine when the next address has been received. This bit is set to 1 if the current value in SCIRD is an address and set to 0 if SCIRD contains data. If the RXWAKE bit is set, then software should check the address in SCIRD against its own address. If it is still being addressed, then sleep mode should remain disabled. Otherwise, the SLEEP bit should be set again.

Following is a sequence of events typical of sleep mode operation:

- The SCI is configured and both sleep mode and receive actions are enabled.
- An address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is not being addressed, so the value of the SLEEP bit is not changed.
- Several data frames are shifted into SCIRXSHF, but no data is moved to SCIRD and no receive interrupts are generated.
- A new address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is being addressed and clears the SLEEP bit.
- Data shifted into SCIRXSHF is transferred to SCIRD, and a receive interrupt is generated after each data frame is received.
- In each interrupt routine, software checks RXWAKE to determine if the current frame is an address frame.
- Another address frame is received, RXWAKE is set, software determines that the SCI is not being addressed and sets the SLEEP bit back to 1. No receive interrupts are generated for the data frames following this address frame.

By ignoring data frames that are not intended for the device, fewer interrupts are generated. These interrupts would otherwise require CPU intervention to read data that is of no significance to this specific device. Using sleep mode can help free some CPU resources.

Except for the RXRDY flag, the SCI continues to update the receiver status flags (see [Table 30-11](#)) while sleep mode is active. In this way, if an error occurs on the receive line, an application can immediately respond to the error and take the appropriate corrective action.

Because the RXRDY bit is not updated for data frames when sleep mode is enabled, the SCI can enable sleep mode and use a polling algorithm if desired. In this case, when RXRDY is set, software knows that a new address has been received. If the SCI is not being addressed, then the software should not change the value of the SLEEP bit and should continue to poll RXRDY.

## 30.7 SCI Control Registers

These registers are accessible in 8-, 16-, and 32-bit reads or writes. The SCI is controlled and accessed through the registers listed in [Table 30-3](#). Among the features that can be programmed are the SCI communication and timing modes, baud rate value, frame format, DMA requests, and interrupt configuration.

**Table 30-3. SCI Control Registers Summary**

| Offset | Acronym        | Register Description               | Section                           |

| <b>Note: Read/Write in privileged mode only.</b> |          |       |                                                            |

### 30.7.2 SCI Global Control Register 1 (SCIGCR1)

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI. Figure 30-9 and Table 30-5 illustrate this register.

**Figure 30-9. SCI Global Control Register 1 (SCIGCR1) [offset = 04h]**

| 9     | POWERDOWN | <p>0 Normal operation.</p> <p>1 Low-power mode is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                            | <p>Power down. When the POWERDOWN bit is set, the SCI attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wake-up interrupt is enabled, then the SCI immediately asserts an error interrupt to prevent low-power mode from being entered. Only Privilege mode writes allowed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 8     | SLEEP     | <p>0 Sleep mode is disabled.</p> <p>1 Sleep mode is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                          | <p>SCI sleep. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI out of sleep mode.</p> <p><b>Note: The receiver still operates when the SLEEP bit is set; however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags (see Table 30-4 ) are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition.</b></p> <p><b>Note: The SLEEP bit is not automatically cleared when an address byte is detected.</b></p> <p>See Section 30.6 for more information on using the SLEEP bit for multiprocessor communication.</p> |
| 7     | SWnRST    | <p>0 The SCI is in its reset state; no data will be transmitted or received. Writing a 0 to this bit initializes the SCI state machines and operating flags as defined in Table 30-11 and Table 30-12. All affected logic is held in the reset state until a 1 is written to this bit.</p> <p>1 The SCI is in its ready state; transmission and reception can be done. After this bit is set to 1, the configuration of the module should not change.</p> | <p>Software reset (active low). This bit is effective in LIN and SCI modes.</p> <p><b>Note: The SCI should only be configured while SWnRESET = 0.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 6     | Reserved  | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 5     | CLOCK     | <p>0 The external SCICLK is the clock source.</p> <p>1 The internal SCICLK is the clock source.</p>                                                                                                                                                                                                                                                                                                                                                       | <p>SCI internal clock enable. The CLOCK bit determines the source of the module clock on the SCICLK pin.</p> <p><b>Note: If an external clock is selected, then the internal baud rate generator and baud rate registers are bypassed. The maximum frequency allowed for an externally sourced SCI clock is VCLK/16.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 4     | STOP      | <p>0 One stop bit is used.</p> <p>1 Two stop bits are used.</p>                                                                                                                                                                                                                                                                                                                                                                                           | <p>SCI number of stop bits per frame.</p> <p><b>Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit (if STOP = 1) to begin checking for an idle period.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Table 30-5. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)**

| Bit | Field       | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----|-------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3   | PARITY      |       | SCI parity odd/even selection. If the PARITY ENA bit is set, PARITY designates odd or even parity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|     |             | 0     | Odd parity is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|     |             | 1     | Even parity is used.<br><br><b>The parity bit is calculated based on the data bits in each frame and the address bit (in address-bit mode). The start and stop fields in the frame are not included in the parity calculation.</b><br><br><b>For odd parity, the SCI transmits and expects to receive a value in the parity bit that makes odd the total number of bits in the frame with the value of 1.</b><br><br><b>For even parity, the SCI transmits and expects to receive a value in the parity bit that makes even the total number of bits in the frame with the value of 1.</b> |
| 2   | PARITY ENA  | 0     | Parity enable. This bit enables or disables the parity function.<br>Parity is disabled; no parity bit is generated during transmission or is expected during reception.                                                                                                                                                                                                                                                                                                                                                                                                                    |
|     |             | 1     | Parity is enabled. ### 30.7.3 SCI Set Interrupt Register (SCISSETINT)

Figure 30-10 and Table 30-6 illustrate this register. SCISSETINT register is used to enable the required interrupts supported by the module.

**Figure 30-10. SCI Set Interrupt Register (SCISSETINT) [offset = 0Ch]**

|       |                | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 23-19 | Reserved       | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 18    | SET RX DMA ALL | 0     | Set receive DMA all. This bit determines if a separate interrupt is generated for the address frames sent in multiprocessor communications. When this bit is 0, RX interrupt requests are generated for address frames and DMA requests are generated for data frames. When this bit is 1, RX DMA requests are generated for both address and data frames.<br><i>Read:</i> The DMA request is disabled for address frames (the receive interrupt request is enabled for address frames).<br><i>Write:</i> Writing a 0 to this bit has no effect. |
|       |                | 1     | <i>Read and write:</i> The DMA request is enabled for address and data frames                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 17    | SET RX DMA     | 0     | Set receiver DMA. To enable receiver DMA requests, this bit must be set. If it is cleared, interrupt requests are generated depending on bit SCISSETINT.<br><i>Read:</i> The DMA request is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                                                                                                    |
|       |                | 1     | <i>Read and write:</i> The DMA request is enabled for address and data frames                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Table 30-6. SCI Set Interrupt Register (SCISSETINT) Field Descriptions (continued)**

| Bit   | Field          | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|----------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16    | SET TX DMA     | 0<br>1 | Set transmit DMA. To enable DMA requests for the transmitter, this bit must be set. If it is cleared, interrupt requests are generated depending on SET TX INT bit (SCISSETINT).<br><i>Read:</i> Transmit DMA request is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read and write:</i> Transmit DMA request is enabled.                                                                                                          |
| 15-10 | Reserved       | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 9     | SET RX INT     | 0<br>1 | Receiver interrupt enable. Setting this bit enables the SCI to generate a receive interrupt after a frame has been completely received and the data is being transferred from SCIRXSHF to SCIRD.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                         |
| 8     | SET TX INT     | 0<br>1 | Set transmitter interrupt. Setting this bit enables the SCI to generate a transmit interrupt as data is being transferred from SCITD to SCITXSHF and the TXRDY bit is being set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                                         |
| 7-2   | Reserved       | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 1     | SET WAKEUP INT | 0<br>1 | Set wakeup interrupt. Setting this bit enables the SCI to generate a wakeup interrupt and thereby exit lowpower mode. If enabled, the wakeup interrupt is asserted when local lowpower mode is requested while the receiver is busy or if a low level is detected on the SCIRX pin during lowpower mode.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled. |
| 0     | SET BRKDT INT  | 0<br>1 | Set breakdetect interrupt. Setting this bit enables the SCI to generate an error interrupt if a break condition is detected on the SCIRX pin.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read or write:</i> The interrupt is enabled.                                                                                                                                                            |

### 30.7.4 SCI Clear Interrupt Register (SCICLEARINT)

Figure 30-11 and Table 30-7 illustrate this register. SCICLEARINT register is used to clear the selected enabled interrupts with out accessing SCISSETINT register.

**Figure 30-11. SCI Clear Interrupt Register (SCICLEARINT) [offset = 10h]**

| 23-19 | Reserved       | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                          |
| 18    | CLR RX DMA ALL | 0     | Clear receive DMA all. This bit clears the receive DMA request for address frames when set. Only receive data frames generate a DMA request.<br><i>Read:</i> Receive DMA request for address frames is disabled; Instead, RX interrupt requests are enabled for address frames. Receive DMA requests are still enabled for data frames.<br><i>Write:</i> Writing a 0 to this bit has no effect. |
|       |                | 1     | <i>Read:</i> The receive DMA request for address and data frames is enabled.<br><i>Write:</i> The receive DMA request for address and data frames is disabled.                                                                                                                                                                                                                                  |
| 17    | CLR RX DMA     | 0     | Clear receive DMA request. This bit disables the receive DMA request when set.<br><i>Read:</i> The DMA request is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                             |
|       |                | 1     | <i>Read:</i> The receive DMA request is enabled.<br><i>Write:</i> The receive DMA request for is disabled.                                                                                                                                                                                                                                                                                      |

**Table 30-7. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions (continued)**

| Bit   | Field          | Value  | Description                                                                                                                                                                                                                                                                                                |
|-------|----------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16    | CLR TX DMA     | 0<br>1 | Clear transmit DMA request. This bit disables the transmit DMA request when set.<br><i>Read:</i> Transmit DMA request is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The transmit DMA request is enabled.<br><i>Write:</i> The transmit DMA request for is disabled. |
| 15-10 | Reserved       | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                     |
| 9     | CLR RX INT     | 0<br>1 | Clear receiver interrupt. This bit disables the receiver interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                      |
| 8     | CLR TX INT     | 0<br>1 | Clear transmitter interrupt. This bit disables the transmitter interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                |
| 7-2   | Reserved       | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                     |
| 1     | CLR WAKEUP INT | 0<br>1 | Clear wakeup interrupt. This bit disables the wakeup interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                          |
| 0     | CLR BRKDT INT  | 0<br>1 | Clear breakdetect interrupt. This bit disables the break-detect interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br><i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                               |

### 30.7.5 SCI Set Interrupt Level Register (SCISSETINTLVL)

Figure 30-12 and Table 30-8 illustrate this register. This register is used to set the interrupt level for the supported interrupts.

**Figure 30-12. SCI Set Interrupt Level Register (SCISSETINTLVL) [offset = 14h]**

Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 26    | FE       | 0     | Framing error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when an expected stop bit is not found. In SCI compatibility mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI/LIN to generate an error interrupt if the SET FE INT bit is set in the register SCISSETINT (SCI Set Interrupt Register (SCISSETINT)). The framing error flag is cleared by the following: <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> <li>Reception of a new character/frame, depending on whether the module is in SCI compatible or LIN mode</li> </ul> In multibuffer mode the frame is defined in the SCIFORMAT register. Read: No framing error has been detected since the last clear. Write: Writing a 0 to this bit has no effect. |
|       |          | 1     | Read: A framing error has been detected since the last clear. Write: The bit is cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 25    | OE       | 0     | Overrun error flag. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD. Detection of an overrun error causes the LIN to generate an error interrupt if the SET OE INT bit = 1. The OE flag is reset by the following: <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> Read: No overrun error has been detected since the last clear. Write: Writing a 0 to this bit has no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|       |          | 1     | Read: An overrun error has been detected since the last clear. Write: The bit is cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| 24    | PE       | <div>0</div> <div>1</div>                           | <p>Parity error flag. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. If the parity function is disabled (SCIGCR[2] = 0), the PE flag is disabled and read as 0. Detection of a parity error causes the LIN to generate an error interrupt if the SET PE INT bit = 1. The PE bit is reset by the following:</p> <ul style="list-style-type: none"><li>Setting of the SW nRST bit</li><li>Setting of the RESET bit</li><li>A system reset</li><li>Writing a 1 to this bit</li><li>Reception of a new character or frame, depending on whether the module is in SCI compatible or LIN mode, respectively.</li><li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li></ul> <p><i>Read:</i> No parity error has been detected since the last clear.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p><i>Read:</i> A parity error has been detected since the last clear.<br/><i>Write:</i> The bit is cleared to 0.</p> |

| 11    | TX EMPTY | <div>0</div> <div>1</div>                           | <p>Transmitter empty flag. This flag indicates the transmitter's buffer register(s) (SCITD/TDy) and shift register (SCITXSHF) are empty.</p> <p><b>Note: The RESET bit, an active SW nRESET (SCIGCR1[7]) or a system reset sets this bit. This bit does not cause an interrupt request.</b></p> <p>Transmitter buffer or shift register (or both) are loaded with data.</p> <p>Transmitter buffer and shift registers are both empty.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 10    | TXWAKE   | <div>0</div> <div>1</div> <div>0</div> <div>1</div> | <p>Transmitter wakeup method select. The TXWAKE bit controls whether the data in SCITD should be sent as an address or data frame using multiprocessor communication format. This bit is set to 1 or 0 by software before a byte is written to SCITD and is cleared by the SCI when data is transferred from SCITD to SCITXSHF or by a system reset.</p> <p><b>Note: TXWAKE is not cleared by the SW nRESET bit.</b></p> <p><i>Address-bit mode</i></p> <p>Frame to be transmitted will be data (address bit = 0).</p> <p>Frame to be transmitted will be an address (address bit = 1).</p> <p><i>Idle-line mode</i></p> <p>The frame to be transmitted will be data.</p> <p>The following frame to be transmitted will be an address (writing a 1 to this bit followed by writing dummy data to the SCITD will result in a idle period of 11 bit periods before the next frame is transmitted).</p>                                                                                                                                                                                                                                                                                                                                                             |

**Table 30-10. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit | Field    | Value                                                                                                                                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9   | RXRDY    | <p>0 Read: No new data is in SCIRD.<br/>Write: Writing a 0 to this bit has no effect.</p> <p>1 Read: New data is ready to be read from SCIRD.<br/>Write: The bit is cleared to 0.</p> | <p>Receiver ready flag. The receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU or DMA. The SCI generates a receive interrupt when RXRDY flag bit is set if the interrupt-enable bit is set (SCISSETINT[9]); RXRDY is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the SCIRD register in compatibility mode</li> <li>Reading the last data byte RDY of the response in LIN mode</li> </ul> <p><b>Note: The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</b></p>                                                                                                                                                                                                                                                         |
| 8   | TXRDY    | <p>0 SCITD is full.</p> <p>1 SCITD is ready to receive the next character.</p>                                                                                                        | <p>Transmitter buffer register ready flag. When set, this bit indicates that the transmit buffer is ready to get another character from a CPU or DMA write.</p> <p>Writing data to SCITD automatically clears this bit. This bit is set after the data of the TX buffer is shifted into the SCITXSHF register. This event can trigger a transmit interrupt after data is copied to the TX shift register SCITXSHF, if the interrupt enable bit TXINT is set.</p> <p><b>Note: 1) TXRDY is also set to 1 either by setting of the RESET bit, enabling SW nRST or by a system reset.</b></p> <p><b>2) The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</b></p> <p><b>3) The transmit interrupt request can be eliminated until the next series of data written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt via the SCICLEARINT register or by disabling the transmitter via the TXENA bit.</b></p> |
| 7-4 | Reserved | 0                                                                                                                                                                                     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 3   | BUSY     | <p>0 The receiver is not currently receiving a frame.</p> <p>1 The receiver is currently receiving a frame.</p>                                                                       | <p>Bus busy flag. This bit indicates whether the receiver is in the process of receiving a frame. As soon as the receiver detects the beginning of a start bit, the BUSY bit is set to 1. When the reception of a frame is complete, the SCI clears the BUSY bit. If SET WAKEUP INT is set and power down is requested while this bit is set, the SCI automatically prevents lowpower mode from being entered and generates wakeup interrupt. The BUSY bit is controlled directly by the SCI receiver, but this bit can also be cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset occurring</li> </ul>                                                                                                                                                                                                                                                                                            |
| 2   | IDLE     | <p>0 The idle period has been detected; the SCI is ready to receive.</p> <p>1 The idle period has not been detected; the SCI will not receive any data.</p>                           | <p>SCI receiver in idle state. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters the idle state if one of the following events occurs:</p> <ul style="list-style-type: none"> <li>A system reset</li> <li>An SCI software reset</li> <li>A power down</li> <li>The RX pin is configured as a general I/O pin</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Table 30-10. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit | Field  | Value                                                                                                                                                                                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | WAKEUP | <p>0 <i>Read:</i> The module will not wake up from power-down mode.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p>1 <i>Read:</i> Wake up from power-down mode.<br/><i>Write:</i> The bit is cleared to 0.</p>                 | <p>Wakeup flag. This bit is set by the SCI when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit (SCISSETINT[2]) is set. It is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p>For compatibility mode, see the SCI document for more information on lowpower mode.</p>                                                                                |
| 0   | BRKDT  | <p>0 <i>Read:</i> No break condition has been detected since the last clear.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p> <p>1 <i>Read:</i> A break condition has been detected.<br/><i>Write:</i> The bit is cleared to 0.</p> | <p>SCI break-detect flag. This bit is set when the SCI detects a break condition on the LINRX pin. A break condition occurs when the SCIRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the BRKDT INT ENA bit is set. The BRKDT bit is reset by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> |

**Table 30-11. SCI Receiver Status Flags**

| SCI Flag | Register | Bit | Value After SW nRESET <sup>(1)</sup> |
|----------|----------|-----|--------------------------------------|
| FE       | SCIFLR   | 26  | 0                                    |
| OE       | SCIFLR   | 25  | 0                                    |
| PE       | SCIFLR   | 24  | 0                                    |
| RXWAKE   | SCIFLR   | 12  | 0                                    |
| RXRDY    | SCIFLR   | 9   | 0                                    |
| BRKDT    | SCIFLR   | 0   | 0                                    |

<sup>(1)</sup> The flags are frozen with their reset value while SW nRESET = 0.

**Table 30-12. SCI Transmitter Status Flags**

| SCI Flag | Register | Bit | Value After SW nRESET <sup>(1)</sup> |
|----------|----------|-----|--------------------------------------|
| TX EMPTY | SCIFLR   | 11  | 1                                    |
| TXRDY    | SCIFLR   | 8   | 1                                    |

<sup>(1)</sup> The flags are frozen with their reset value while SW nRESET = 0.

### 30.7.8 SCI Interrupt Vector Offset 0 (SCIINTVECT0)

Figure 30-15 and Table 30-13 illustrate this register.

**Figure 30-15. SCI Interrupt Vector Offset 0 (SCIINTVECT0) [offset = 20h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 30-13. SCI Interrupt Vector Offset 0 (SCIINTVECT0) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 3-0  | INVECT0  | 0-Fh  | Interrupt vector offset for INT0. This register indicates the offset for interrupt line INT0. A read to this register updates its value to the next highest priority pending interrupt in SCIFLR and clears the flag in SCIFLR corresponding to the offset that was read. See Table 30-1 for a list of the interrupts.<br><br><b>Note: The flags for the receive (SCIFLR[9]) and the transmit (SCIFLR[8]) interrupt cannot be cleared by reading the corresponding offset vector in this register (see detailed description in SCIFLR register).</b> |

### 30.7.9 SCI Interrupt Vector Offset 1 (SCIINTVECT1)

Figure 30-16 and Table 30-14 illustrate this register.

**Figure 30-16. SCI Interrupt Vector Offset 1 (SCIINTVECT1) [offset = 24h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 30-14. SCI Interrupt Vector Offset 1 (SCIINTVECT1) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 3-0  | INVECT1  | 0-Fh  | Interrupt vector offset for INT1. This register indicates the offset for interrupt line INT1. A read to this register updates its value to the next highest priority pending interrupt in SCIFLR and clears the flag in SCIFLR corresponding to the offset that was read. See Table 30-1 for list of interrupts.<br><br><b>Note: The flags for the receive (SCIFLR[9]) and the transmit (SCIFLR[8]) interrupt cannot be cleared by reading the corresponding offset vector in this register (see detailed description in SCIFLR register).</b> |

### 30.7.10 SCI Format Control Register (SCIFORMAT)

Figure 30-17 and Table 30-15 illustrate this register.

**Figure 30-17. SCI Format Control Register (SCIFORMAT) [offset = 28h]**

LEGEND: R/W = Read/Write; R = Read only; WC = Write in SCI-compatible mode only; -n = value after reset

**Table 30-15. SCI Format Control Register (SCIFORMAT) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                        |
| 2-0  | CHAR     | 0-7h  | Character length control bits. These bits set the SCI character length from 1 to 8 bits.<br><b>When data of fewer than eight bits in length is received, it is left justified in SCIRD and padded with trailing zeros. Data read from the SCIRD should be shifted by software to make the received data right justified.</b><br><b>Data written to the SCITD should be right justified but does not need to be padded with leading zeros.</b> |
|      |          | 0     | The character is 1 bit long.                                                                                                                                                                                                                                                                                                                                                                                                                  |
|      |          | 1h    | The character is 2 bits long.                                                                                                                                                                                                                                                                                                                                                                                                                 |
|      |          | 2h    | The character is 3 bits long.                                                                                                                                                                                                                                                                                                                                                                                                                 |
|      |          | 3h    | The character is 4 bits long.                                                                                                                                                                                                                                                                                                                                                                                                                 |
|      |          | 4h    | The character is 5 bits long.                                                                                                                                                                                                                                                                                                                                                                                                                 |
|      |          | 5h    | The character is 6 bits long.                                                                                                                                                                                                                                                                                                                                                                                                                 |
|      |          | 6h    | The character is 7 bits long.                                                                                                                                                                                                                                                                                                                                                                                                                 |
|      |          | 7h    | The character is 8 bits long.                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 30.7.11 Baud Rate Selection Register (BRS)

This section describes the baud rate selection register. [Figure 30-18](#) and [Table 30-16](#) illustrate this register.

**Figure 30-18. Baud Rate Selection Register (BRS) [offset = 2Ch]**

| 15624                 | 003BA0 | 200           | 200    | 0.00          |
| 624999                | 098967 | 5             | 5      | 0.00          |

<sup>(1)</sup> VCLK = 50 MHz

<sup>(2)</sup> Values are in decimal except for column 2.

### 30.7.12 SCI Data Buffers (SCIED, SCIRD, SCITD)

The SCI has three addressable registers in which transmit and receive data is stored.

#### 30.7.12.1 Receiver Emulation Data Buffer (SCIED)

The SCIED register is addressed at a location different from SCIRD, but is physically the same register.

[Figure 30-19](#) and [Table 30-18](#) illustrate this register.

**Figure 30-19. Receiver Emulation Data Buffer (SCIED) [offset = 30h]**

|     |          |  |  |  |  |  |  |  |     |   |    |  |  |  |  |  |    |
|-----|----------|--|--|--|--|--|--|--|-----|---|----|--|--|--|--|--|----|
| 31  | Reserved |  |  |  |  |  |  |  |     |   |    |  |  |  |  |  | 16 |
| R-0 |          |  |  |  |  |  |  |  |     |   |    |  |  |  |  |  |    |
| 15  | Reserved |  |  |  |  |  |  |  | 8   | 7 | ED |  |  |  |  |  | 0  |

**Table 30-18. Receiver Emulation Data Buffer (SCIED) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                          |
|------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                               |
| 7-0  | ED       | 0-FFh | Emulator data. Reading SCIED[7:0] does not clear the RXRDY flag, unlike reading SCIRD. This register should be used only by an emulator that must continually read the data buffer without affecting the RXRDY flag. |

#### 30.7.12.2 Receiver Data Buffer (SCIRD)

This register provides a location for the receiver data. [Figure 30-20](#) and [Table 30-19](#) illustrate this register.

**Figure 30-20. Receiver Data Buffer (SCIRD) [offset = 34h]**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                     |
|------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                          |
| 7-0  | RD       | 0-FFh | Receiver data. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag is set and a receive interrupt is generated if SET RX INT is set.<br><b>Note: When the data is read from SCIRD, the RXRDY flag is automatically cleared.</b> |

**NOTE:** When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left-justified format padded with trailing zeros. Therefore, the user software should perform a logical shift on the data by the correct number of positions to make it right justified.

### 30.7.12.3 Transmit Data Buffer Register (SCITD)

Data to be transmitted is written to the SCITD register. [Figure 30-21](#) and [Table 30-20](#) illustrate this register.

**Figure 30-21. Transmit Data Buffer Register (SCITD) [offset = 38h]**

|          |  |  |  |  |  |  |  |       |   |  |  |  |  |  |  |    |   |

| R-0      |  |  |  |  |  |  |  | R/W-0 |   |  |  |  |  |  |  |    |   |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 30-20. Transmit Data Buffer Register (SCITD) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                 |
|------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                      |
| 7-0  | TD       | 0-FFh | Transmit data. Data to be transmitted is written to the SCITD register. The transfer of data from this register to the transmit shift register SCITXSHF sets the TXRDY flag, which indicates that SCITD is ready to be loaded with another byte of data.<br><b>Note: If TX INT ENA is set, this data transfer also causes an interrupt.</b> |

**NOTE:** Data written to the SCITD register that is fewer than eight bits long must be right justified, but it does not need to be padded with leading zeros.

### 30.7.13 SCI Pin I/O Control Register 0 (SCIPIO0)

[Figure 30-22](#) and [Table 30-21](#) illustrate this register.

LEGEND: R/W = Read/Write; R = Read only; WC = Write in sci-compatible mode only; WP = Write in privilege mode only; -n = value after reset

**NOTE:**

1. All the bits are used in IODFT mode only.
2. Each IODFT are expected to be checked individually.

**Table 30-32. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions**

| Bit   | Field           | Value | Description                                                                                                                                                                                                   |
|-------|-----------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-27 | Reserved        | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                        |
| 26    | FEN             | 0     | Frame error enable. This bit is used to create a frame error.<br>No error is created.                                                                                                                         |
|       |                 | 1     | The stop bit received is ANDed with 0 and passed to the stop bit check circuitry.                                                                                                                             |
| 25    | PEN             | 0     | Parity error enable. This bit is used to create a parity error.<br>No parity error occurs.                                                                                                                    |
|       |                 | 1     | The parity bit received is toggled so that a parity error occurs.                                                                                                                                             |
| 24    | BRKD TENA       | 0     | Break detect error enable. This bit is used to create a BRKDT error.<br>No error is created.                                                                                                                  |
|       |                 | 1     | The stop bit of the frame is ANDed with 0 and passed to the RSM so that a frame error occurs. Then the RX pin is forced to continuous low for 10 T <sub>BITS</sub> so that a BRKDT error occurs.              |
| 32-21 | Reserved        | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                        |
| 20-19 | PIN SAMPLE MASK | 0     | Pin sample mask. These bits define the sample number at which the TX pin value that is being transmitted will be inverted to verify the receive pin samples majority detection circuitry.<br>No mask is used. |
|       |                 | 1h    | Invert the TX Pin value at 7th.SCLK.                                                                                                                                                                          |
|       |                 | 2h    | Invert the TX Pin value at 8th.SCLK.                                                                                                                                                                          |
|       |                 | 3h    | Invert the TX Pin value at 9th.SCLK.                                                                                                                                                                          |

**Table 30-32. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions (continued)**

| Bit   | Field    | Value      | Description                                                                                                                                                                                                                                                  |
|-------|----------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 18-16 | TX SHIFT |            | Transmit shift. These bits define the amount by which the value on TX pin is delayed so that the value on the RX pin is asynchronous. This feature is not applicable to the start bit.                                                                       |
|       |          | 0          | No delay occurs.                                                                                                                                                                                                                                             |
|       |          | 1h         | The value is delayed by 1 SCLK.                                                                                                                                                                                                                              |
|       |          | 2h         | The value is delayed by 2 SCLK.                                                                                                                                                                                                                              |
|       |          | 3h         | The value is delayed by 3 SCLK.                                                                                                                                                                                                                              |
|       |          | 4h         | The value is delayed by 4 SCLK.                                                                                                                                                                                                                              |
|       |          | 5h         | The value is delayed by 5 SCLK.                                                                                                                                                                                                                              |
|       |          | 6h         | The value is delayed by 6 SCLK.                                                                                                                                                                                                                              |
|       |          | 7h         | No delay occurs.                                                                                                                                                                                                                                             |
| 15-12 | Reserved | 0          | Read returns 0. Writes have no effect.                                                                                                                                                                                                                       |
| 11-8  | IODFTENA |            | IODFT enable key. Write access permitted in Privilege mode only.                                                                                                                                                                                             |
|       |          | Ah         | IODFT is enabled.                                                                                                                                                                                                                                            |
|       |          | All Others | IODFT is disabled.                                                                                                                                                                                                                                           |
| 7-2   | Reserved | 0          | Read returns 0. Writes have no effect.                                                                                                                                                                                                                       |
| 1     | LPBENA   |            | Module loopback enable. Write access permitted in Privilege mode only.<br><b>Note: In analog loopback mode the complete communication path through the I/Os can be tested, whereas in digital loopback mode the I/O buffers are excluded from this path.</b> |
|       |          | 0          | Digital loopback is enabled.                                                                                                                                                                                                                                 |
|       |          | 1          | Analog loopback is enabled in module I/O DFT mode when IODFTENA = 1010.                                                                                                                                                                                      |
| 0     | RXPENA   |            | Module analog loopback through receive pin enable. Write access permitted in Privilege mode only.<br>This bit defines whether the I/O buffers for the transmit or the receive pin are included in the communication path (in analog loopback mode)           |
|       |          | 0          | Analog loopback through the transmit pin is enabled.                                                                                                                                                                                                         |
|       |          | 1          | Analog loopback through the receive pin is enabled.                                                                                                                                                                                                          |

## 30.8 GPIO Functionality

The following sections apply to all device pins that can be configured as functional or general-purpose I/O pins.

### 30.8.1 GPIO Functionality

Figure 30-32 illustrates the GPIO functionality.

**Figure 30-32. GPIO Functionality**

### 30.8.2 Under Reset

The following apply if a device is under reset:

- Pull control. The reset pull control on the pins is enabled or disabled depending on a device-specific option. This feature is configurable for each module separately.
- Input buffer. Input buffer is enabled.
- Output buffer. The output buffer is disabled.

### 30.8.3 Out of Reset

The following apply if the device is out of reset:

- Pull control. The pull control is enabled by clearing the PD (pull control disable) bit in the SCIPIO7 register (Section 30.7.20). In this case, if the PSL (pull select) bit in the SCIPIO8 register (Section 30.7.21) is set, the pin will have a pull-up. If the PSL bit is cleared, the pin will have a pull-down. If the PD bit is set in the control register, there is no pull-up or pull-down on the pin.
- Input buffer. The input buffer is always enabled in functional mode.

---

**NOTE:** The pull-disable logic depends on the pin direction. It is independent of whether the device is in I/O or functional mode. If the pin is configured as output or transmit, then the pulls are disabled automatically. If the pin is configured as input or receive, the pulls are enabled or disabled depending on bit PD in the pull disable register SCIPIO7 (Section 30.7.20).

---

- Output buffer. A pin can be driven as an output pin if the TX DIR bit is set in the pin direction control register (SCIPIO1; Section 30.7.14) AND the open-drain feature is not enabled in the SCIPIO6 register (Section 30.7.19).

### 30.8.4 Open-Drain Feature Enabled on a Pin

The following apply if the open-drain feature is enabled on a pin:

- The output buffer is enabled if a low signal is being driven on to the pin.
- The output buffer is disabled (the direction control signal DIR is internally forced low) if a high signal is being driven on to the pin.

---

**NOTE:** The open-drain feature is available only in I/O mode (SCIPIO0; Section 30.7.13).

---

### 30.8.5 Summary

The behavior of the input buffer, output buffer, and the pull control is summarized in Table 30-33.

**Table 30-33. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins <sup>(1)</sup>**

| Device under Reset? | Pin Direction (DIR) <sup>(2)</sup> | Pull Disable (PULDIS) <sup>(3)</sup> | Pull Select (PULSEL) <sup>(4)</sup> | Pull Control                | Output Buffer | Input Buffer |
|---------------------|------------------------------------|--------------------------------------|-------------------------------------|-----------------------------|---------------|--------------|
| Yes                 | X                                  | X                                    | X                                   | Device- and module-specific | Disabled      | Enabled      |
| No                  | 0                                  | 0                                    | 0                                   | Pull down                   | Disabled      | Enabled      |
| No                  | 0                                  | 0                                    | 1                                   | Pull up                     | Disabled      | Enabled      |
| No                  | 0                                  | 1                                    | 0                                   | Disabled                    | Disabled      | Enabled      |
| No                  | 0                                  | 1                                    | 1                                   | Disabled                    | Disabled      | Enabled      |
| No                  | 1                                  | X                                    | X                                   | Disabled                    | Enabled       | Enabled      |

<sup>(1)</sup> X = Don't care

<sup>(2)</sup> DIR = 0 for input, 1 for output

<sup>(3)</sup> PULDIS = 0 for enabling pull control  
= 1 for disabling pull control

<sup>(4)</sup> PULSEL = 0 for pull-down functionality  
= 1 for pull-up functionality

## ***Inter-Integrated Circuit (I2C) Module***

This chapter describes the inter-integrated circuit (I2C or I<sup>2</sup>C) module. The I2C is a multi-master communication module providing an interface between the Texas Instruments (TI) microcontroller and devices compliant with Philips Semiconductor I<sup>2</sup>C-bus specification version 2.1 and connected by an I2C-bus. This module will support any slave or master I2C compatible device.

## 31.1 Overview

The I2C has the following features:

- Compliance to the Philips I<sup>2</sup>C bus specification, v2.1 (*The I2C Specification*, Philips document number 9398 393 40011)
  - Bit/Byte format transfer
  - 7-bit and 10-bit device addressing modes
  - General call
  - START byte
  - Multi-master transmitter/ slave receiver mode
  - Multi-master receiver/ slave transmitter mode
  - Combined master transmit/receive and receive/transmit mode
  - Transfer rates of 10 kbps up to 400 kbps (Phillips fast-mode rate)
- Free data format
- Two DMA events (transmit and receive)
- DMA event enable/disable capability
- Seven interrupts that can be used by the CPU
- Operates with VBUS frequency from 6.7 MHz up
- Operates with module frequency between 6.7 MHz to 13.3 MHz
- Module enable/disable capability
- The SDA and SCL are optionally configurable as general purpose I/O
- Slew rate control of the outputs
- Open drain control of the outputs
- Programmable pullup/pulldown capability on the inputs
- Supports Ignore NACK mode

**NOTE:** This I2C module does **not** support:

- High-speed (HS) mode
- C-bus compatibility mode
- The combined format in 10-bit address mode (the I2C sends the slave address second byte every time it sends the slave address first byte)

### 31.1.1 Introduction to the I2C Module

The I2C module supports any slave or master I2C-compatible device. [Figure 31-1](#) shows an example of multiple I2C serial ports connected for a two-way transfer from one device to another device.

**Figure 31-1. Multiple I2C Modules Connection Diagram**

### 31.1.2 Functional Overview

The I2C module is a serial bus that supports multiple master devices. In multimaster mode, one or more devices can be connected to the same bus and are capable of controlling the bus. Each I2C device on the bus is recognized by a unique address and can operate as either a transmitter or a receiver, depending on the function of the device. In addition to being a transmitter or receiver, a device connected to the I2C bus can also be considered a master or a slave when performing data transfers.

---

**NOTE:** A master device is the device that initiates the data transfer on a bus and generates the clock signal that permits the transfer. During the transmission, any device addressed by the master is considered the slave.

---

Data is communicated to devices interfacing to the I2C module using the serial data pin (SDA) and the serial clock pin (SCL) as shown in [Figure 31-2](#). These two wires carry information between the device and the other devices connected to the I2C bus. Both SDA and SCL pins on the device are bidirectional. They must be connected to a positive supply voltage through a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the wired-AND function.

The device has a special mode that can be entered to ignore a NACK generated from non-compliant I2C devices that are incapable of generating an ACK.

The I2C module consists of the following primary blocks:

- A serial Interface: one data pin (SDA) and one clock pin (SCL)
- The device register interface
  - Data registers to temporarily hold received data and transmitted data traveling between the SDA pin and the CPU or the DMA
  - Control and status registers
- A prescaler to divide down the input clock that is driven to the I2C module
- A peripheral bus interface to enable the CPU and DMA to access the I2C module registers
- An arbitrator to handle arbitration between the I2C module (when configured as a master) and another master
- Interrupt generation logic (interrupts can be sent to the CPU)
- A clock synchronizer that synchronizes the I2C input clock (from the system module) and the clock on the SCL pin, and synchronizes data transfers with masters of different clock speeds.
- A noise filter on each of the two serial pins
- DMA event generation logic that synchronizes data reception and data transmission in the I2C module for DMA transmission

In [Figure 31-2](#), the CPU or the DMA writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

When the I2C function is not needed, the pins may be controlled as general-purpose input/output (GPIO) pins. The I/O structure of each pin includes:

- programmable slew rate control of the outputs
- open drain mode
- programmable pull enable/disable on the input
- programmable pull up/pull down function on the input

**Figure 31-2. Simple I2C Block Diagram**

### 31.1.3 Clock Generation

As shown in [Figure 31-3](#), the I2C module uses the input clock generated from the device clock generator to generate the module clock and master clock. The I2C input clock is the device peripheral clock (VBUS\_CLK). The clock is then divided twice more inside the I2C module to produce the module clock and the master clock.

**Figure 31-3. Clocking Diagram for the I2C Module**

The module clock determines the frequency at which the I2C module operates. A programmable prescaler in the I2C module divides down the input clock to produce the module clock. To specify the divide-down value, initialize the I2CPSC field of the prescaler register, I2CPSC. The resulting frequency is:

$$\text{ModuleClockFrequency} = \frac{\text{I2CInputClockFrequency}}{(\text{I2CPSC} + 1)} \quad (66)$$

The module clock frequency must be between 6.7MHz and 13.3MHz. The prescaler can only be initialized while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the I2CPSC value while IRS = 1 has no effect.

The master clock appears on the SCL pin when the I2C module is configured to be a master on the I2C bus. This clock controls the timing of the communication between the I2C module and a slave. As shown in [Figure 31-3](#), a second clock divider in the I2C module divides down the module clock to produce the master clock. The clock divider uses the I2CCKL to divide down the low portion of the module clock signal and uses the I2CCKH to divide down the high portion of the module clock signal.

The resulting frequency is:

$$\text{MasterClockFrequency} = \frac{\text{ModuleClockFrequency}}{(\text{I2CCKL} + d) + (\text{I2CCKH} + d)} \quad (67)$$

$$\text{MasterClockFrequency} = \frac{\text{I2CInputClockFrequency}}{(\text{I2CPSC} + 1)((\text{I2CCKL} + d) + (\text{I2CCKH} + d))} \quad (68)$$

where  $d$  depends on the value of I2CPSC:

| I2CPSC         | d |
|----------------|---|
| 0              | 7 |
| 1              | 6 |
| Greater than 1 | 5 |

---

**NOTE:** The master clock frequency defined above does not include rise/fall time and latency of the synchronizer inside the module. The actual transfer rate will be slower than the value calculated from the formula above. Also, due to the nature of SCL synchronization, the SCL clock period could change if SCL synchronization is taking place.

---

## 31.2 I2C Module Operation

The following section discusses how the I2C module operates.

### 31.2.1 Input and Output Voltage Levels

One clock pulse is generated by the master device for each data bit transferred. Because of a variety of different technology devices that can be connected to the I2C-bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of  $V_{CCIO}$ . For details, see the device specific data sheet.

### 31.2.2 I2C Module Reset Conditions

The I2C module can be reset in the following two ways:

- Through the global peripheral reset. A device reset causes a global peripheral reset.
- By clearing the  $\overline{IRS}$  bit in the I2C mode register (I2CMODR). When the global peripheral reset is removed, the  $\overline{IRS}$  bit is cleared to 0, keeping the I2C module in the reset state.

### 31.2.3 I2C Module Data Validity

The data on the SDA must be stable during the high period of the clock. See [Figure 31-4](#). The high and low state of the data line, the SDA, can only change when the clock signal is low.

**Figure 31-4. Bit Transfer on the I2C Bus**

### 31.2.4 I2C Module Start and Stop Conditions

START and STOP conditions are generated by a master I2C module.

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A master drives this condition to indicate the start of data transfer. The bus is considered to be busy after the START condition, and the bus busy bit (BB) in I2CSR is set to 1.
- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A master drives this condition to indicate the end of data transfer. The bus is considered to be free after the STOP condition, therefore the BB bit in I2CSR is cleared to 0.

Figure 31-5. I2C Module START and STOP Conditions

For the I2C module to start a data transfer with a START condition, the master mode bit (MST) and the START condition bit (STT) in the I2CMDR must both be set to 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated.

### 31.2.5 Serial Data Formats

The I2C module operates in byte data format. Each message put on the SDA line is 2 to 8-bits long. The number of messages that can be transmitted or received is unrestricted. The data is transferred with the most significant bit (MSB) first (Figure 31-6). Each message is followed by an acknowledge bit from the I2C if it is in receiver mode. The I2C module does not support little endian systems.

Figure 31-6. I2C Module Data Transfer

The first byte after a START condition (S) always consists of 8 bits that comprise either a 7-bit address plus the R/W bit, or 8 data bits. The eighth bit, R/W, in the first byte determines the direction of the data. When the R/W bit is 0, the master writes (transmits) data to a selected slave device; when the R/W bit is 1, the master reads (receives) data from the slave device. In acknowledge mode, an extra bit dedicated for the acknowledgement (ACK) bit is inserted after each message.

The I2C module supports the following formats:

- 7-bit addressing format (Figure 31-7)
- 10-bit addressing format (Figure 31-8)
- 7-bit/10-bit addressing format with repeated START condition (Figure 31-9)
- Free-data format (Figure 31-10)

### 31.2.5.1 7-Bit Addressing Format

In the 7-bit addressing format (Figure 31-7), the first byte after the START condition consists of a 7-bit slave address followed by the  $R/\overline{W}$  bit (in the LSB). The  $R/\overline{W}$  bit determines the direction of the data transfer:

- $R/\overline{W} = 0$ : The master writes (transmits) data to the addressed slave.
- $R/\overline{W} = 1$ : The master reads (receives) data from the slave.

An extra clock cycle dedicated for acknowledgement (ACK) is inserted after each byte. If the ACK is inserted by the slave after the first byte from the master, it is followed by n bits of data from the transmitter (master or slave, depending on the  $R/\overline{W}$  bit). The device I2C allows n to be a number between 2 to 8, programmable by the bit count (BC) field of I2CMDR. After the data bits have been transferred, the receiver inserts an ACK bit.

To select the 7-bit addressing format, write 0 to the expanded address enable (XA) bit of I2CMDR and make sure the free data format mode is off (FDF = 0 in I2CMDR).

**Figure 31-7. I2C Module 7-Bit Addressing Format**

### 31.2.5.2 10-Bit Addressing Format

The 10-bit addressing format is similar to the 7-bit addressing format, but the master sends the slave address in two separate byte transfers. In the 10-bit addressing format (Figure 31-8), the first byte is 11110b, the two MSBs of the 10-bit slave address, and the  $R/\overline{W}$  bit. The ACK bit is inserted after each byte. The second byte is the remaining 8 bits of the 10-bit slave address. The slave must send an acknowledgement after each of the two byte transfers. Once the master has written the second byte to the slave, the master can either write data or use repeated a START condition to change the data direction.

To select the 10-bit addressing format, write 1 to the expanded address enable (XA) bit of I2CMDR and make sure the free data format mode is off (FDF = 0 in I2CMDR).

**Figure 31-8. I2C Module 10-bit Addressing Format**

### 31.2.5.3 Using the Repeated START Condition

At the end of each byte, the master can drive another START condition (Figure 31-9). Using this capability, a master can transmit/receive any number of data bytes before generating a STOP condition. The length of a data byte can be from 2 to 8 bits. The repeated START condition can be used with the 7-bit addressing, 10-bit addressing, or the free data formats.

**Figure 31-9. I2C Module 7-Bit Addressing Format with Repeated START**

### 31.2.5.4 Free Data Format

In this format (Figure 31-10), the first byte after a START condition is a data byte. The ACK bit is inserted after each byte, followed by another 8 bits of data. No address or data direction bit is sent. Therefore, the transmitter and receiver must both support the free data format. The direction of data transmission (transmit or receive) remains constant throughout the transfer.

To select the free data format, write a 1 to the free data format (FDF) bit of the I2CMDR. The free data format is not supported in the digital loop back mode.

**Figure 31-10. I2C Module in Free Data Format**

### 31.2.6 NACK Bit Generation

When the I2C module is a receiver (master or slave), it can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. Table 31-1 summarizes the various ways a NACK can be generated.

**Table 31-1. Ways to Generate a NACK Bit**

| I2C Module Condition                               | Basic NACK Bit Generation Options                                                                                                                                               | Additional Option                                                                      |
|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Slave receiver mode                                | Disable data transfers (STT = 0)Allow an overrun condition (RSFULL = 1)Reset the module (IRS = 0)                                                                               | Set the NACKMOD bit before the rising edge of the last data bit you intend to receive. |
| Master receiver mode and repeat mode (RM = 1)      | Generate a STOP condition (STP = 1)Reset the module (IRS = 0)                                                                                                                   | Set the NACKMOD bit before the rising edge of the last data bit you intend to receive. |
| Master receiver mode with non-repeat mode (RM = 0) | If STP = 1, allow the internal data counter to count down to 0 and thus force a STOP condition.If STP = 0, make STP = 1 to generate a STOP condition.Reset the module (IRS = 0) | Set the NACKMOD bit before the rising edge of the last data bit you intend to receive. |

In some applications, the slave cannot generate the ACK signal. If the IGNACK bit is set in the I2CEMDR register, the resulting NACK will be ignored and the I2C block will continue the data transfer.

## 31.3 I2C Operation Modes

### 31.3.1 Master Transmitter Mode

All masters begin in this mode. The I2C module is a master and transmits control information and data to a slave. In this mode, data assembled in any of the addressing formats shown in [Figure 31-7](#), [Figure 31-8](#), or [Figure 31-9](#) is shifted out onto the SDA pin and synchronized with the self-generated clock pulses on the SCL pin. The clock pulses are inhibited and the SCL pin is held low when the intervention of the device is required ( $\overline{XSMT} = 0$ ) after a byte has been transmitted.

---

**NOTE:** If the I2C is configured for two simultaneous master transmissions, wait until the MST and BB have been reset before performing the second master transmission.

---

Failure to wait for the MST and BB to reset will prevent the start condition on the second transfer from being issued and the bus BB will not be set. Typically the end of the first transfer is handled by polling BB. However, the MST bit is not reset at the same instant as the BB bit. As a result, when the second master transmission is initiated before the resetting of the MST, the MST bit for the second transfer is reset. This prevents the I2C from recognizing itself as the master, thus failing to occupy the bus.

### 31.3.2 Master Receiver Mode

In this mode, the I2C module is a master and receives data from a slave. This mode can only be entered from the master transmitter mode (the I2C module must first transmit a command to the slave). In any of the addressing formats shown in [Figure 31-7](#), [Figure 31-8](#), or [Figure 31-9](#), the master receiver mode is entered after the slave address byte and the R/W bit have been transmitted (if the R/W bit is 1). Serial data bits received on the SDA pin are shifted in with the self-generated clock pulses on the SCL pin. The clock pulses are inhibited and the SCL is held low when the intervention of the device is required ( $RSFULL = 1$ ) after a byte has been received. At the end of the transfer, the master-receiver signals the end of data to the slave-transmitter by not generating an acknowledge on the last byte that was clocked out of the slave. The slave-transmitter then releases the data line allowing the master-receiver to generate a STOP condition or a repeated START condition.

In many applications, the size of the message is in the initial bytes of the message itself. Since the size of the message is not known to the master before the transmission/reception starts, the master must use the repeat mode in order to force the stop condition when the reception is completed. The repeat mode is enabled by setting the RM bit to 1. Due to the double buffer implementation on the receive side, the master must generate the stop condition ( $STP = 1$ ) after reading the (message size - 1)<sup>th</sup> data.

### 31.3.3 Slave Transmitter Mode

In this mode, the I2C module is a slave and transmits data to a master. This mode can only be entered from the slave receiver mode (The I2C module must first receive a command from the master). In any of the addressing formats shown in [Figure 31-7](#), [Figure 31-8](#), or [Figure 31-9](#), the slave transmitter mode is entered if the slave address byte is the same as its own address and the R/W bit has been transmitted (if the R/W bit is set to 1). The slave transmitter shifts the serial data out on the SDA pin with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it can hold the SCL pin low when intervention of the device is required ( $\overline{XSMT} = 0$ ) after a byte has been transmitted.

### 31.3.4 Slave Receiver Mode

In this mode, the I2C module is a slave and receives data from a master. All slaves begin in this mode. Serial data bits received on the SDA pin are shifted in with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it can hold the SCL pin low while intervention of the device is required ( $RSFULL = 1$ ) after a byte has been received.

### 31.3.5 Low Power Mode

The I2C module can be placed in low-power mode by a global low-power mode initiated by the system (by writing to the Peripheral Power-Down Set Register in the Peripheral Central Resource (PCR) module.

In effect, low-power mode shuts down all the clocks to the module. In global low-power mode, no registers are visible to the software; nothing can be written to or read from any register.

### 31.3.6 Free Run Mode

The I2C module can be placed in free run mode when the FREE bit (I2CMDR.14) is set to 1. This bit is primarily used on an emulator when encountering a breakpoint while debugging software. When the FREE bit is set to 0, the I2C responds differently depending on whether the SCL is high or low. If the SCL is low, the I2C stops immediately and keeps driving the SCL low whether the I2C is the master transmitter or receiver. If the SCL is high, the I2C waits until the SCL becomes a low and then stops. If the I2C is a slave, it stops when the transmission/reception completes.

### 31.3.7 Ignore NACK Mode

The I2C module can be placed in the ignore NACK mode by setting the IGNACK bit in the I2CEMDR register. This mode allows an I2C module that is configured as a master transmitter to ignore a NACK from a slave device that is not capable of generating a proper ACK signal.

## 31.4 I2C Module Integrity

The following section discusses how the I2C module maintains priorities and order among signals and commands.

### 31.4.1 Arbitration

If two or more master transmitters simultaneously start a transmission on the same bus, an arbitration procedure is invoked. [Figure 31-11](#) illustrates the arbitration procedure between two devices. The arbitration procedure uses the data presented on the SDA bus by the competing transmitters. The first master transmitter that generates a high is overruled by the other master that generates a low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. The master transmitter that loses the arbitration switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration-lost interrupt. The data transmitted by the other master module is salvaged, and the I2C continues to receive data from the master module. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If, during a serial transfer, the arbitration procedure is still in progress when a repeated START condition or STOP condition is transmitted to I2C bus, the master transmitters involved must send the repeated START condition or STOP condition at the same position in the format frame. In other words, arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

Slaves are not involved in the arbitration procedure.

**Figure 31-11. Arbitration Procedure Between Two Master Transmitters**

### 31.4.2 I2C Clock Generation and Synchronization

Under normal conditions only one master device generates the clock signal; the SCL. During the arbitration procedure, however, there are two or more master devices and the clock must be synchronized so that the data output can be compared. Figure 31-12 illustrates clock synchronization. The wired-AND property of the SCL line means that a device that first generates a low period on the SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start their own low period. The SCL line is held low by the device with the longest low period. The other devices that finish their low periods must wait for the SCL line to be released before starting their high periods. A synchronized signal on the SCL is obtained where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a slave slows down a fast master and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

#### NOTE: I2C Protocol Fault

The following conditions violate the clock spec as defined in the Philips I<sup>2</sup>C bus specification, v2.1 (*The I2C Specification*, Philips document number 9398 393 40011), and will result in an I2C protocol fault:  $I2CCLKH = 2$   $I2CCLKL = 2I2CPSC = 2$  This will cause the SDA data transition to occur while the SCL is high.

**Figure 31-12. Synchronization of Two I2C Clock Generators During Arbitration**

### 31.4.3 Prescaler

The I2C module is operated by the module clock. This clock is generated by way of the I2C prescaler block. The prescaler block consists of a 8-bit register, I2CPSC, used for dividing down the device peripheral clock (VBUS\_CLK) to obtain a module clock between 6.7 MHz and 13.3 MHz.

### 31.4.4 Noise Filter

The noise filter is used to suppress any noises that are 50ns or less. It is designed to suppress noise with one module clock, assuming the lower and upper limits of the module clock are 6.7MHz and 13.3MHz, respectively.

## 31.5 Operational Information

The following section provides specific information about how the I2C module operates.

### 31.5.1 I2C Module Interrupts

The I2C module generates seven types of interrupts. These seven interrupts are accompanied with seven interrupt mask bits in the interrupt mask register (I2CIMR) and with seven interrupt flag bits in the status register (I2CSR).

#### 31.5.1.1 I2C Interrupt Requests

The I2C module generates the interrupt requests described below. All requests are multiplexed through an arbiter into a single I2C interrupt request to the CPU. Each interrupt request has a flag bit and an enable bit. Interrupts must be enabled prior to the occurrence of the expected interrupt condition. When one of the specified events occurs, the flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the interrupt request is forwarded to the CPU as an I2C interrupt request. As an alternative, the CPU can poll all of the bits shown in [Table 31-2](#).

**Table 31-2. Interrupt Requests Generated by I2C Module**

| Flag  | Name                            | Generated                                                                                                                                                                                                                                    |
|-------|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AL    | Arbitration-lost interrupt      | Generated when the I2C module has lost an arbitration contest with another master-transmitter                                                                                                                                                |
| NACK  | No-acknowledge interrupt        | Generated when the master I2C does not receive an acknowledge from the receiver                                                                                                                                                              |
| ARDY  | Register-access-ready interrupt | Generated when the previously programmed address, data and command have been performed and the status bits have been updated. The interrupt is used to notify the device that the I2C registers are ready to be accessed.                    |
| RXRDY | Receive-data-ready interrupt    | Generated when the received data in the receive-shift register (I2CSR) has been copied into the data receive register (I2CDRR). The RXRDY bit can also be polled by the device to determine when to read the received data in the I2CDRR.    |
| TXRDY | Transmit-data-ready interrupt   | Generated when the transmitted data has been copied from the data transmit register (I2CDXR) into the transmit-shift register (I2CXSR). The TXRDY bit can also be polled by the device to determine when to write the next data into I2CDXR. |
| SCD   | Stop-condition-detect interrupt | Generated when a STOP condition has been detected.                                                                                                                                                                                           |
| AAS   | Address-as-slave interrupt      | Generated when the I2C has recognized its own slave address or an address of all zeroes.                                                                                                                                                     |

The interrupt vector register (I2CIVR) contains the binary-coded-interrupt vector that indicates the highest priority interrupt that is pending and enabled. When I2CIVR is read, the corresponding interrupt flags for AL, NACK and SCD are automatically cleared, if their interrupts are enabled. Reading the I2CIVR will not clear the AAS, ARDY, RXRDY, or TXRDY interrupt pending flags. Please see section [Section 31.6.3, I2C Status Register \(I2CSTR\)](#) for the method to clear these four flags.

If more than one interrupt is pending, a new interrupt will be generated for the next highest priority pending interrupt when you re-enable the I2C interrupt.

A transmit interrupt is generated just after the START condition in master transmitter mode. This ensures that the CPU will get an interrupt even if no slave returns an ACK to the slave address following the START condition.

It is important to note that when the I2C is configured to generate interrupts as a slave transmitter and the backward compatibility mode (BCM) bit is set to 1, an extra transmit interrupt occurs. The application should monitor the ACK from the master to determine whether to load another byte into I2CDXR. See Appendix A: Backward Compatibility Mode, for more information.

### 31.5.2 DMA Controller Events

The I2C module has two events that use the DMA controller to synchronously read received data (I2CREVNT) from I2CDRR, and synchronously write data (I2CWEVNT) to the transmit buffer, I2CDXR. The read and write events have the same timing as I2CRRDY (I2CRINT) and I2CXRDY (I2CXINT), respectively.

The CPU or the DMA controller reads the received data from I2CDRR and writes the data to be transmitted to I2CDXR. The RXRDY bit is automatically cleared when the DMA controller reads the I2CDRR register, and the TXRDY bit is automatically cleared when the DMA controller writes to the I2CDXR register.

Data written to I2CDXR is copied to I2CXSR and shifted out from the SDA pin when the I2C module is configured as a transmitter. When the I2C module is configured as a receiver, received data is shifted into ICRSR and copied to I2CDRR, which can be read by the CPU or the DMA controller.

A transmit event (I2CWEVNT) is generated after a START condition in master transmitter mode. This ensures that the DMA gets an event even if no slave returns an ACK to the slave address following the START condition.

---

**NOTE: Unexpected DMA transmit and receive event**

An unexpected DMA transmit event (ICXEVT) and a DMA receive event (ICXRDY) are generated in 10-bit, master transmit, repeat mode. This event occurs soon after the start condition but before the first bit of the address is transmitted. In this event, no DMA activity should be initiated without the slave ACK being received.

---

### 31.5.3 I2C Enable/Disable

The I2C module can be enabled or disabled with the I2C reset enable bit (IRS) in the I2C module register (I2CMMDR). This occurs in one of two ways:

- Write 0 to the I2C reset bit (IRS) in I2CMMDR. All status bits are forced to the default values and the I2C mode remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high impedance state.
- Initiate a device reset by driving the  $\overline{\text{PORRST}}$  pin low. The entire device is reset and is held in the reset state until the pin is released and is driven high. When  $\overline{\text{PORRST}}$  is released, all I2C module registers are reset to their default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until a 1 is written to the IRS bit.

IRS must be 0 while the I2C module is being configured. Forcing IRS to 0 can be used to save power and also clear error conditions.

### 31.5.4 General Purpose I/O

Both of the I2C pins can be programmed to be general-purpose I/O pins via the I2C pin control registers (I2CPFNC, I2CDIR, I2CDOOUT, and I2CDIN).

When the I2C module is not used, the I2C pins may be programmed to be either general purpose input or general-purpose output pins. This function is controlled in the I2CDIR and I2CPFNC registers. Note that each pin can be programmed to be either an I2C pin or a GIO pin.

If the I2C function is to be used, the application software must ensure that each pin is configured as an I2C pin and not a GIO pin, or else unexpected behavior may result.

### 31.5.5 Pull Up/Pull Down Function

I2C module pins can have either an active pull up or active pull down that makes it possible to leave the pins unconnected externally. The pins can be programmed to have the active pull function enabled or disabled by writing to the corresponding bit in the I2CPDIS register. Please see the device-specific data sheet for the default internal pull (pull-up, pull-down or no pull) on the pins.

The pull on the pins is programmable to a setting other than the default internal pull as specified in the data sheet. The pins can be programmed to have either an active pull up or an active pull down function by writing to the corresponding bit in I2CPSEL register. The pull up/pull down function is active on the pin only when the pull enabled is programmed in the I2CPDIS register.

The pull up/pull down functions are deactivated when a bidirectional pin is configured as an output. At system reset, the pull up function of all the pins is disabled. Please see the device-specific data sheet for the current supplied by the pull up/pull down.

### 31.5.6 Open Drain Function

The I2C pins can be programmed to include an open drain function when they are configured as output pins. This is done by writing to the corresponding bit of the I2CPDR register. When the open drain function is enabled, a low value (0) written to the data output register forces the pin to a low output voltage ( $V_{OL}$  or lower), whereas a high value (1) written to the data output register forces the pin to a high impedance state. The open drain function is disabled when the pin is configured as an input pin.

## 31.6 I2C Registers

[Table 31-3](#) provides a summary of the registers.

The upper word (upper 16 bits) of the below registers are all read as 0s. Writes have no effect on these bits. For a more detailed description of the individual bits, see the following sections.

**Table 31-3. I2C Control Register Summary**

| Offset  | Acronym  | Register Description               | Section                         |
|---------|----------|------------------------------------|---------------------------------|

| 15-10 | Reserved | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 9-0   | OA       | 0-3FFh | Own address<br>These bits reflect the bus address of the I2C module. When the expand address (XA) bit I2CMDR.8 is set to 1, the I2C is in expand address mode (10-bit addressing mode). In either 7 or 10-bit address mode, all 10-bits are both readable and writable. Bits 7, 8, and 9 should only be used in 10-bit address mode. <a href="#">Table 31-5</a> provides the correct modes for these bits. Note that the user can program the I2C own address to any value as long as it does not conflict with other components in the system. |

**Table 31-5. Correct Mode for Bits OA.9:0**

| Bits Used | Mode              | Value of XA |
|-----------|-------------------|-------------|
| OA.6:0    | 7 Bit Addressing  | 0           |
| OA.9:0    | 10 Bit Addressing | 1           |

### 31.6.2 I2C Interrupt Mask Register (I2CIMR)

The 7-bit memory mapped I2C interrupt mask register is used by the device to enable/disable the interrupts. [Figure 31-14](#) and [Table 31-6](#) describe this register.

**Figure 31-14. I2C Interrupt Mask Register (I2CIMR) [Offset = 04h]**

### 31.6.3 I2C Status Register (I2CSTR)

Figure 31-15 and Table 31-7 describe this register.

| 14  | SDIR     | 0     | Slave direction<br>Setting this bit to 1 indicates that the I2C slave is a transmitter. Clearing this bit to 0 indicates that the I2C is a master transmitter/receiver or a slave receiver. This bit is also cleared by the STOP or START conditions. In DLB mode (in which the configuration should be master-transmitter slave-receiver), this bit is cleared to 0.<br><b>Writing a 1 to this bit will clear it.</b><br>The I2C is a master transmitter/receiver or a slave receiver.                                                                                                                                                                                                                                                              |
|     |          | 1     | The I2C is a slave transmitter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 13  | NACKSNT  | 0     | No acknowledge sent<br>This bit is set to 1 to indicate that a no acknowledgement (NACK) has been sent because the NACKMOD bit was set to 1.<br><b>Writing a 1 to this bit will clear it.</b><br>A NACK has not been sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|     |          | 1     | A NACK was sent because the NACKMOD was set to 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 12  | BB       | 0     | Bus busy<br>This bit indicates the state of the serial bus.<br>On reception of a START condition or if the I2C detects a low state on I2CSCL, the device sets BB = 1. If the nIRS is set to 1 during transaction between other I2C devices, the BB bit is set at the first falling edge of SCL or START condition.<br>BB is cleared to 0 after the reception of a STOP condition. BB is kept to 0 regardless of the SCL state when the I2C is in reset (nIRS = 0).<br>The bus is free.                                                                                                                                                                                                                                                               |
|     |          | 1     | The bus is busy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 11  | RSFULL   | 0     | Receiver shift full<br>This bit is set to 1 to indicate that the receiver has experienced overrun. Overrun occurs when the receive shift register is full and I2CDRR has not been read since the receive shift register to I2CDRR transfer. The contents of I2CDRR are not lost. The I2C core logic is holding for I2CDRR read access. This bit is also set when, in master-repeat-mode, the I2C receives a byte of data. There is no difference between RXRDY and RSFULL in this case. The I2C master will not continue the transfer as long as the received data is in the I2CDRR or receive shift register.<br><b>RSFULL is cleared when reading the I2CDRR, resetting the I2C (IRS_=0), or resetting the device.</b><br>No overrun has occurred. |
|     |          | 1     | An overrun has occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 31-7. I2C Status Register (I2CSTR) Field Descriptions (continued)**

| Bit | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|----------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10  | XSMT     | 0<br>1 | <p>Transmit shift empty</p> <p>This bit is cleared to 0 to indicate that the transmitter has experienced underflow. Underflow occurs when the transmit shift register is empty and I2CDXR has not been loaded since the last I2CDXR to transmit shift register transfer. The I2C core logic is waiting for I2CDXR write access.</p> <p><b>XMSTn is set to 1 as a result of writing to I2CDXR, by resetting the I2C block(IRS=0), or by resetting the device.</b></p> <p>In repeat mode, if the I2C in master transmitter mode is holding transfer with XSMTn = 0 (that is, waiting for further action) and the STT or STP bit is set, XSMTn is set to 1 by hardware.</p> <p>An underflow has occurred.</p> <p>No underflow has occurred.</p> |

| Bit | Field | Value             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----|-------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | ARDY  | <p>0</p> <p>1</p> | <p>Register access ready interrupt flag</p> <p>This bit is set to 1 when the previously programmed address, data and command has been performed and the status bit has been updated. The flag is used by the device to indicate that the I2C registers are ready to be accessed again.</p> <p><b>This bit is automatically cleared by hardware when writing data to I2CDXR in transmit mode, reading data from I2CDRR in receive mode, or setting STT or STP bit. Writing a 1 to this bit will clear this bit. This bit cannot be cleared by reading the I2CIVR register.</b></p> <p>When RM=0, ARDY is set when I2CCNT is passed 0 if STP register bit has not been set. When RM=1, ARDY is set at each byte end.</p> <p>When FDF is 0, ARDY is asserted after the ACK for the slave address. When FDF is 1, there is no slave address. Therefore, ARDY is asserted after sending the start condition.</p> <p><i>Nonrepeat mode, (RM = 0):</i> I2C registers are not ready to be accessed.<br/> <i>Repeat mode (RM = 1):</i> I2C registers are not ready to be accessed.</p> <p><i>Nonrepeat mode, (RM = 0):</i> ICCNT passes 0 (if STP bit has not been set).<br/> <i>Repeat mode (RM = 1):</i> The end of each byte was transmitted from I2CDXR.</p> |
| 1   | NACK  | <p>0</p> <p>1</p> | <p>No acknowledgement interrupt</p> <p>This bit is set to 1 when the master I2C does not receive an acknowledgement from the receiver. This bit is set only when the I2C has received a no-acknowledge in master mode. This bit is NOT set by no-acknowledgement after Start byte. In master start byte mode, the first byte (address of all zeroes) receives a NACK but does not clear the stop bit.</p> <p><b>Writing a 1 to this bit or reading the value 0x0002 from I2CIVR will clear this bit.</b></p> <p>An acknowledge was detected.</p> <p>No acknowledge was detected or the I2C is operating in the general call, even though an acknowledgement was received. This value clears the STP bit.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 0   | AL    | <p>0</p> <p>1</p> | <p>Arbitration lost interrupt flag</p> <p>This bit is set to 1 when arbitration has been lost.</p> <p><b>Writing a 1 to this bit or reading the value 0x0001 from I2CIVR will clear this bit.</b></p> <p>No loss of arbitration has been detected.</p> <p>The device in the master transmitter mode senses it has lost an arbitration. This occurs when two or more transmitters start a transmission almost simultaneously or when the I2C attempts to start a transfer while BB=1. When this is set to 1 due to arbitration lost, the device becomes a slave receiver and the MST, STT and STP bits in I2CMDR are cleared to 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### 31.6.4 I2C Clock Divider Low Register (I2CCKL)

The I2C clock divider low register is a 16-bit memory mapped register used to divide the master clock down to obtain the I2C serial clock low time. [Figure 31-16](#) and [Table 31-8](#) describe this register.

**Figure 31-16. I2C Clock Divider Low Register (I2CCKL) [Offset = 0Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 31-8. I2C Clock Divider Low Register (I2CCKL) Field Descriptions**

| Bit  | Field | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | CLKL  | 0-FFFFh | <p>Low time clock division factor</p> <p>Used to divide down the module clock to create the low time portion of the master clock signal that will appear on the SCL pin.:</p> $LowTime = \left( \frac{I2CCKL + d}{ModuleClockFrequency} \right) \quad (69)$ <p>where <i>d</i> is the value that depends on the I2CPSC (see <a href="#">Section 31.1.3</a>).</p> <p>This register must be configured while the I2C is still in reset (nIRS = 0).</p> |

### 31.6.5 I2C Clock Control High Register (I2CCKH)

The I2C clock divider high register is a 16-bit memory mapped register used to divide the master clock down to obtain the I2C serial clock high time. [Figure 31-17](#) and [Table 31-9](#) describe this register.

**Figure 31-17. I2C Clock Control High Register (I2CCKH) [Offset = 10h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 31-9. I2C Clock Control High Register (I2CCKH) Field Descriptions**

| Bit  | Field | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------|-------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | CLKH  | 0-FFFFh | <p>High time clock division factor</p> <p>Used to divide down the module clock to create the high time portion of the master clock signal that will appear on the SCL pin:</p> $HighTime = \left( \frac{I2CCKH + d}{ModuleClockFrequency} \right) \quad (70)$ <p>where <i>d</i> is the value that depends on the I2CPSC (see <a href="#">Section 31.1.3</a>).</p> <p>This register must be configured while the I2C is still in reset (nIRS = 0).</p> |

### 31.6.6 I2C Data Count Register (I2CCNT)

The I2C data count register is a 16-bit memory mapped register used to count received or transmitted data bytes. This register is also used to generate the STOP condition which terminates the transfer after the counter reaches zero. [Figure 31-18](#) and [Table 31-10](#) describe this register.

**Figure 31-18. I2C Data Count Register (I2CCNT) [Offset = 14h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 31-10. I2C Data Count Register (I2CCNT) Field Descriptions**

| Bit  | Field | Value   | Description                                                                                                                                                                    |
|------|-------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|      |       | 0       | The data counter is 65536.                                                                                                                                                     |
|      |       | 1       | The data counter is 1.                                                                                                                                                         |

### 31.6.7 I2C Data Receive Register (I2CDRR)

The I2C data receive register is a 16-bit memory mapped register used by the device to read the received data. [Figure 31-19](#) and [Table 31-11](#) describe this register.

**Figure 31-19. I2C Data Receive Register (I2CDRR) [Offset = 18h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 31-11. I2C Data Receive Register (I2CDRR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                 |
|------|----------|-------|-------------------------------------------------------------------------------------------------------------|
| 15-8 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                      |
| 7-0  | DATARX   | 0-FFh | Receive data<br>A read from this register clears the RXRDY bit and clears code 4h from the I2CIVR register. |

### 31.6.8 I2C Slave Address Register (I2CSAR)

The I2C slave address register is a 16-bit memory-mapped register used to specify the address of the slave device to communicate to on the I2C bus. [Figure 31-20](#) and [Table 31-12](#) describe this register.

**Figure 31-20. I2C Slave Address Register (I2CSAR) [Offset = 1Ch]**

|-----|----------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15  | NACKMOD  | 0<br>1 | No-acknowledge (NACK) mode<br>This bit is used to send an acknowledge (ACK) or a no-acknowledge (NACK) to the transmitter. This bit is only applicable when the I2C is in receiver mode. In master receiver mode, when the internal data counter decrements to zero, the I2C sends a NACK. The master receiver I2C finishes a transfer when it sends a NACK. The I2C ignores ICCNT when NACKMOD is 1. The NACKMOD bit should be set before the rising edge of the last data bit if a NACK must be sent, and this bit is cleared once a NACK has been sent.<br>The I2C sends an ACK to the transmitter during the acknowledge cycle.<br>The I2C sends a NACK to the transmitter during the acknowledge cycle. |
| 14  | FREE     | 0<br>1 | Free running bit<br>This bit is used to determine the state of the I2C when a breakpoint is encountered in the high level language (HLL) debugger.<br>The I2C stops immediately if SCL is low and keeps driving SCL low if the I2C master is a transmitter/receiver. If SCL is high, I2C waits until SCL becomes low and then stops. If the I2C is a slave, it will stop when the transmission/reception completes.<br>The I2C runs free.                                                                                                                                                                                                                                                                    |
| 13  | STT      | 0<br>1 | Start condition<br>The start condition bit works with the STP bit (master only mode). The STT and STP bits are configured to generate different transfer formats (see Table 31-16). The STT and STP bits can be used to terminate the repeat mode. This bit takes one I2C module clock cycle to set.<br>The STT is reset to 0 by the hardware after the START condition has been generated.<br>STT is set to 1 by the device to generate a START condition. In master mode, setting STT to 1 generates a START condition.                                                                                                                                                                                    |
| 12  | Reserved | 0      | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 11  | STP      | 0<br>1 | Stop condition<br>1(Master mode only) This bit can be set to a 1 by the CPU to generate a stop condition. It is reset to 0 by the hardware after the stop condition has been generated. The stop condition is generated when ICCNT passes 0 when the I2C is in non-repeat mode (RM=0). In repeat mode (RM=1), the stop condition is generated if STP bit is 1. In transmitter mode, I2CTXRDY needs to be 1 (i.e. you have to set STP bit unless you write data into I2CDXR).<br>STP is reset to 0 by the hardware after the STOP condition has been generated.<br>STP is set to 1 by the device to generate a STOP condition.                                                                                |
| 10  | MST      | 0<br>1 | Master/slave mode bit<br>This bit determines whether the module will operate in master or slave mode; see Table 31-17. This bit is cleared after generating a STOP condition. The BB bit is cleared first, and MST bit is cleared second. Before starting the next transaction in master mode, this bit must be confirmed to be cleared.<br>The module is in the slave mode and the clock is received from the master device.<br>The module is in the master mode and it generates the clock. This bit is cleared when the transfer has completed.                                                                                                                                                           |

**Table 31-15. I2C Mode Register (I2CMDR) Field Descriptions (continued)**

| Bit | Field | Value             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|-------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9   | TRX   | <p>0</p> <p>1</p> | <p>Transmit/receive bit</p> <p>This bit determines the direction of data transmission of the I2C module. See <a href="#">Table 31-17</a>.</p> <p>The module is in the receive mode and data on the SDA line is shifted into the data register I2CDRR.</p> <p>The module is in the transmit mode and the data in the I2CDXR is shifted out on the SDA line.</p>                                                                                                                                                                                                                                                                                                                                               |
| 8   | XA    | <p>0</p> <p>1</p> | <p>Expand address enable bit</p> <p>This bit controls the addressing mode. When XA is set to 1, the I2C does not support the combined format in master mode operations. However, the I2C will acknowledge and support the formats when configured as a slave. This bit needs to be configured even if the I2C is in slave mode.</p> <p>The mode is set to 7-bit addressing mode (normal address mode).</p> <p>The mode is set to 10-bit addressing mode (expanded address mode).</p>                                                                                                                                                                                                                         |
| 7   | RM    | <p>0</p> <p>1</p> | <p>Repeat mode enable bit (Master mode only)</p> <p>This bit is a 'don't care' if the module is configured in slave mode (MST = 0); see <a href="#">Table 31-16</a>. Each time a byte of data is received, the user should decide whether or not to continue receiving more data. See <a href="#">Figure 31-23</a> for a diagram of this function.</p> <p>The mode is not in repeat mode.</p> <p>In repeat mode, data is continuously transmitted out of the ICDXR or received into the ICDRR until the STP bit is set to 1 regardless of ICCNT value. See <a href="#">Table 31-16</a> for module conditions.</p>                                                                                            |
| 6   | DLB   | <p>0</p> <p>1</p> | <p>Digital loop back enable bit</p> <p>This bit disables or enables the digital loopback mode of the I2C. This bit only applies in Master transmitter mode.</p> <p>Digital loop back mode is disabled.</p> <p>Digital loop back mode is enabled. In digital loop back mode, data transmitted out of the I2CDXR will be received in the I2CDRR. The address of the I2COAR is output on SDA.</p>                                                                                                                                                                                                                                                                                                               |
| 5   | nIRS  | <p>0</p> <p>1</p> | <p>I2C reset enable bit</p> <p>When set to 0, this bit will place all status registers in this module to their default state. Resetting nIRS during a data transfer can hang the I2C bus.</p> <p>I2C is in reset.</p> <p>I2C is out of reset.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 4   | STB   | <p>0</p> <p>1</p> | <p>Start byte mode enable bit (Master mode only)</p> <p>The Start byte mode bit is set to 1 by the CPU to configure the I2C in Start byte mode. The I2C sends "00000001" regardless of the I2CSAR value. Refer to the Philips I2C specification for more details.</p> <p>The module is not in START byte mode.</p> <p>The module is in START byte mode.</p>                                                                                                                                                                                                                                                                                                                                                  |
| 3   | FDF   | <p>0</p> <p>1</p> | <p>Free data format enable bit</p> <p>This bit configures the module to operate in free data format mode (see <a href="#">Table 31-17</a>) in both master and slave modes. When FDF is 0, ARDY is asserted after ACK for the slave address. When FDF is 1, there is no slave address. Therefore, ARDY is asserted after sending the start condition. FDF mode is not supported in digital loop back mode.</p> <p>The module is not in free data format mode.</p> <p>The module is in free data format mode.</p>                                                                                                                                                                                              |
| 2-0 | BC    |                   | <p>Bit count</p> <p>This bit defines the number of bits starting from the LSB (excluding the acknowledge bit) that are sent on the bus when data is written to the data transmit register.</p> <p>If the bits BC0, BC1, and BC2 are all 0, then the number of bits sent on the bus is 8. If the bit count bits are a non-zero value, then the number of bits sent on the bus is that value. The value "001" is reserved. When performing a transfer using the bit count of, for example, n (where n is nonzero), only the n least significant bits in the data receive register are valid and correct. The rest of the bits should be disregarded. See <a href="#">Table 31-18</a> for more information.</p> |

### 31.6.11 I2C Interrupt Vector Register (I2CIVR)

The I2C interrupt vector register is a 16-bit memory-mapped register used to indicate the occurrence of an interrupt. [Figure 31-24](#) and [Table 31-19](#) describe this register.

**Figure 31-24. I2C Interrupt Vector Register (I2CIVR) [Offset = 28h]**

|          |    |        |   |          |   |         |   |
|----------|----|--------|---|----------|---|---------|---|

| 2-0   | INTCODE  | 0-3h  | <p>Interrupt Code Bits</p> <p>This binary coded interrupt vector indicates which interrupt has occurred. If there is more than one interrupt pending, reading I2CIVR provides the vector for the highest priority interrupt that is pending.</p> <p>Reading the I2CIVR will clear the corresponding flags in I2CSTR for AL, NACK and SCD as long as those interrupts are enabled. A new interrupt will be generated for each pending source.</p> <p>Reading I2CIVR will clear the INTCODE for AL, NACK, SCD, AAS, RXRDY and TXRDY. Reading I2CIVR <b>will not</b> clear the INTCODE for ARDY.</p> <p>The INTCODE for certain codes can also be cleared by either writing a 1 to the corresponding interrupt flag bits in I2CSTR, or by reading and writing to the receive or transmit registers. See <a href="#">Section 31.6.3</a> for more details.</p> <p>Users must read (clear) the I2CIVR before doing another start otherwise the I2CIVR could contain incorrect (old interrupt flag) value.</p> |

**Table 31-20. Interrupt Codes for INTCODE Bit**

| Code | INTCODE(2-0)           | Interrupt Occurred             |
|------|------------------------|--------------------------------|
| 00   | 000                    | none                           |
| 01h  | 001 (highest priority) | Arbitration lost (AL)          |
| 02h  | 010                    | No acknowledgement (NACK)      |
| 03h  | 011                    | Receive access ready (ARDY)    |
| 04h  | 100                    | Receive data ready (RXRDY)     |
| 05h  | 101                    | Transmit data ready (TXRDY)    |
| 06h  | 110                    | Stop condition detection (SCD) |
| 07h  | 111 (lowest priority)  | Address as slave (AAS)         |

### 31.6.12 I2C Extended Mode Register (I2CEMDR)

The I2C extended mode register is a 16-bit memory-mapped register that contains additional mode select bits. [Figure 31-25](#) and [Table 31-21](#) describe this register.

**Figure 31-25. I2C Extended Mode Register (I2CEMDR) [Offset = 2Ch]**

| 15-2 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 1    | IGNACK   | 0     | Ignore NACK mode<br>The master transmitter will operate normally, discontinue the data transfer, and set the ARDY and NACK status bits when a NACK signal is received from the slave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|      |          | 1     | The master transmitter will ignore a NACK received from the slave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 0    | BCM      |       | Backwards compatibility mode<br>When set to 1, the I2C is compatible with previous versions of the I2C. This means the TXRDY interrupt is generated in slave-transmit mode when TXRDY is set and the I2C needs more data to transmit. This behavior causes an extra TXRDY interrupt to be generated because the I2C recognizes the end of transfer after generating an interrupt for the next byte of data.<br>When BCM is 0, the TXRDY interrupt in slave-transmit mode is generated when XSMT = 1. In this case, the I2C generates an interrupt for the next byte after receiving the ACK from previous data. The setting of this bit only applies to slave transmit mode. |
|      |          | 0     | The I2C is <b>not</b> in compatibility mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|      |          | 1     | The I2C is in compatibility mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### 31.6.13 I2C Prescale Register (I2CPSC)

The I2C prescaler register is a 16-bit memory-mapped register used for dividing down the VBUS\_CLK to obtain a module clock frequency between 6.7 MHz and 13.3 MHz. [Figure 31-26](#) and [Table 31-22](#) describe this register.

**Figure 31-26. I2C Prescale Register (I2CPSC) [Offset = 30h]**

|          |  |   |   |       |
|----------|--|---|---|-------|

### 31.6.21 I2C Data Set Register (I2CDSET)

The I2CDSET register is an alias of the I2CDOUT register. When written to at this address, writing a 1 to a bit sets the corresponding bit in I2CDOUT to a 1, while writing a 0 leaves it unchanged. [Figure 31-34](#) and [Table 31-30](#) describe this register.

**Figure 31-34. I2C Data Set Register (I2CDSET) [Offset = 58h]**

|          |  |   |        |        |

### 31.6.23 I2C Pin Open Drain Register (I2CPDR)

A value of 1 in the I2CPDR register configures the corresponding pin for open drain capability. A value of 0 disables this open drain capability of the pin. [Figure 31-36](#) and [Table 31-32](#) describe this register.

**Figure 31-36. I2C Pin Open Drain Register (I2CPDR) [Offset = 60h]**

### 31.6.24 I2C Pull Disable Register (I2CPDIS)

Values in the I2CPDIS register enable or disable the pull control capability of the pins. A 0 in the I2CPDIS register enables the pull function of the corresponding pin, while a 1 disables the pull function. [Figure 31-37](#) and [Table 31-33](#) describe this register.

**Figure 31-37. I2C Pull Disable Register (I2CPDIS) [Offset = 64h]**

### 31.6.25 I2C Pull Select Register (I2CPSEL)

Values in the I2CPSEL register select the pull up or pull down functions of the corresponding pins. A 0 in the I2CPSEL register enables the pull down function of the corresponding pin, while a 1 enables the pull up function of the corresponding pin. [Figure 31-38](#) and [Table 31-34](#) describe this register.

**Figure 31-38. I2C Pull Select Register (I2CPSEL) [Offset = 68h]**

## 32.1 Introduction

This document provides a functional description of the Ethernet Media Access Controller (EMAC) and physical layer (PHY) device Management Data Input/Output (MDIO) module integrated in the microcontroller. Included are the features of the EMAC and MDIO modules, a discussion of their architecture and operation, how these modules connect to the outside world, and a description of the registers for each module.

The EMAC controls the flow of packet data from the system to the PHY. The MDIO module controls PHY configuration and status monitoring.

Both the EMAC and the MDIO modules interface to the system core through a custom interface that allows efficient data transmission and reception. This custom interface is referred to as the EMAC control module and is considered integral to the EMAC/MDIO peripheral.

### 32.1.1 Purpose of the Peripheral

The EMAC module is used to move data between the device and another host connected to the same network, in compliance with the Ethernet protocol.

### 32.1.2 Features

The EMAC/MDIO has the following features:

- Synchronous 10/100 Mbps operation.
- Standard Media Independent Interface (MII) and/or Reduced Media Independent Interface (RMII) to physical layer device (PHY).
- EMAC acts as DMA master to either internal or external device memory space.
- Eight receive channels with VLAN tag discrimination for receive quality-of-service (QOS) support.
- Eight transmit channels with round-robin or fixed priority for transmit quality-of-service (QOS) support.
- Ether-Stats and 802.3-Stats statistics gathering.
- Transmit CRC generation selectable on a per channel basis.
- Broadcast frames selection for reception on a single channel.
- Multicast frames selection for reception on a single channel.
- Promiscuous receive mode frames selection for reception on a single channel (all frames, all good frames, short frames, error frames).
- Hardware flow control.
- 8k-byte local EMAC descriptor memory that allows the peripheral to operate on descriptors without affecting the CPU. The descriptor memory holds enough information to transfer up to 512 Ethernet packets without CPU intervention. (This memory is also known as CPPI RAM.)
- Programmable interrupt logic permits the software driver to restrict the generation of back-to-back interrupts, which allows more work to be performed in a single call to the interrupt service routine.

### 32.1.3 Functional Block Diagram

Figure 32-1 shows the three main functional modules of the EMAC/MDIO peripheral:

- EMAC control module
- EMAC module
- MDIO module

The EMAC control module is the main interface between the device core processor to the EMAC and MDIO modules. The EMAC control module controls device interrupts and incorporates an 8k-byte internal RAM to hold EMAC buffer descriptors (also known as CPPI RAM).

The MDIO module implements the 802.3 serial management interface to interrogate and control up to 32 Ethernet PHYs connected to the device by using a shared two-wire bus. Host software uses the MDIO module to configure the autonegotiation parameters of each PHY attached to the EMAC, retrieve the negotiation results, and configure required parameters in the EMAC module for correct operation. The module is designed to allow almost transparent operation of the MDIO interface, with very little maintenance from the core processor.

The EMAC module provides an efficient interface between the processor and the network. The EMAC on this device supports 10Base-T (10 Mbits/sec) and 100BaseTX (100 Mbits/sec), half-duplex and full-duplex mode, and hardware flow control and quality-of-service (QOS) support.

Figure 32-1 shows the main interface between the EMAC control module and the CPU. The following connections are made to the device core:

- The DMA bus connection from the EMAC control module allows the EMAC module to read and write both internal and external memory through the DMA memory transfer controller.
- The EMAC control, EMAC, and MDIO modules all have control registers. These registers are memory-mapped into device memory space. Along with these registers, the control module's internal CPPI RAM is mapped into this same range.
- The EMAC and MDIO interrupts are combined into four interrupt signals within the control module. The Vectored Interrupt Manager (VIM) receives all four interrupt signals from the combiner and submits these interrupt requests to the CPU.

Figure 32-1. EMAC and MDIO Block Diagram

### **32.1.4 Industry Standard(s) Compliance Statement**

The EMAC peripheral conforms to the IEEE 802.3 standard, describing the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer specifications. The IEEE 802.3 standard has also been adopted by ISO/IEC and re-designated as ISO/IEC 8802-3:2000(E).

However, the EMAC deviates from the standard in the way it handles transmit underflow errors. The EMAC MII interface does not use the Transmit Coding Error signal MTXER. Instead of driving the error pin when an underflow condition occurs on a transmitted frame, the EMAC intentionally generates an incorrect checksum by inverting the frame CRC, so that the transmitted frame is detected as an error by the network.

## 32.2 Architecture

This section discusses the architecture and basic function of the EMAC peripheral.

### 32.2.1 Clock Control

All internal EMAC logic is clocked synchronously on the VCLKA4 domain. Please refer to the "Architecture" chapter of the technical reference manual for more details.

The MDIO clock is based on a divide-down of the VCLK3 peripheral bus clock and is specified to run up to 2.5 MHz (although typical operation would be 1.0 MHz). Because the VCLK3 peripheral clock frequency is configurable, the application software or driver must control the divide-down value.

The transmit and receive clock sources are provided by the external PHY to the MII\_TXCLK and MII\_RXCLK pins or to the RMI reference clock pin. Data is transmitted and received with respect to the reference clocks of the interface pins.

The MII interface frequencies for the transmit and receive clocks are fixed by the IEEE 802.3 specification as:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps

The RMI interface frequency for the transmit and receive clocks are fixed at 50 MHz for both 10 Mbps and 100 Mbps.

### 32.2.2 Memory Map

The EMAC peripheral includes internal memory that is used to hold buffer descriptions of the Ethernet packets to be received and transmitted. This internal RAM is 2K × 32 bits in size. Data can be written to and read from the EMAC internal memory by either the EMAC or the CPU. It is used to store buffer descriptors that are 4-words (16-bytes) deep. This 8K local memory holds enough information to transfer up to 512 Ethernet packets without CPU intervention. This EMAC RAM is also referred to as the CPPI buffer descriptor memory because it complies with the Communications Port Programming Interface (CPPI) v3.0 standard.

The packet buffer descriptors can also be placed in other on- and off-chip memories such as the CPU RAM. There are some tradeoffs in terms of interconnect bandwidth when descriptors are placed in the CPU RAM, versus when they are placed in the EMAC's internal memory. In general, the EMAC throughput is better when the descriptors are placed in the local EMAC CPPI RAM.

### 32.2.3 Signal Descriptions

The microcontrollers support both the MII and the RMI interfaces. Only one of these two interfaces can be used at a time. A separate control register in the I/O Multiplexing Module (IOMM) allows the application to indicate the actual interface being used. This is the bit 24 of the PINMMR29 control register. This bit is set by default and selects the RMI interface. The application can select the MII interface by clearing this bit. Please refer the I/O Multiplexing Module chapter of the technical reference manual for more details on the procedure to configure the PINMMR registers.

Each of the EMAC and MDIO signals for the MII and RMI interfaces are multiplexed with other I/O functions on this microcontroller. Please refer to [Section 32.2.4](#) for information on configuration of the multiplexing control registers to enable the MII / RMI connections to these I/Os.

#### 32.2.3.1 Media Independent Interface (MII) Connections

[Figure 32-2](#) shows a device with integrated EMAC and MDIO interfaced via a MII connection in a typical system. The EMAC module does not include a transmit error (MTXER) pin. In the case of transmit error, CRC inversion is used to negate the validity of the transmitted frame.

The individual EMAC and MDIO signals for the MII interface are summarized in [Table 32-1](#). For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

**Figure 32-2. Ethernet Configuration—MII Connections**

**Table 32-1. EMAC and MDIO Signals for MII Interface**

| Signal       | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MII_TXCLK    | I    | Transmit clock (MII_TXCLK). The transmit clock is a continuous clock that provides the timing reference for transmit operations. The MII_TXD and MII_TXEN signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.                                                                                                                                                                                                                                                                                                                       |
| MII_TXD[3-0] | O    | Transmit data (MII_TXD). The transmit data pins are a collection of 4 data signals comprising 4 bits of data. MTDX0 is the least-significant bit (LSB). The signals are synchronized by MII_TXCLK and valid only when MII_TXEN is asserted.                                                                                                                                                                                                                                                                                                                                                                             |
| MII_TXEN     | O    | Transmit enable (MII_TXEN). The transmit enable signal indicates that the MII_TXD pins are generating nibble data for use by the PHY. It is driven synchronously to MII_TXCLK.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| MII_COL      | I    | Collision detected (MII_COL). In half-duplex operation, the MII_COL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists. This signal is not necessarily synchronous to MII_TXCLK nor MII_RXCLK.<br><br>In full-duplex operation, the MII_COL pin is used for hardware transmit flow control. Asserting the MII_COL pin will stop packet transmissions; packets in the process of being transmitted when MII_COL is asserted will complete transmission. The MII_COL pin should be held low if hardware transmit flow control is not used. |
| MII_CRS      | I    | Carrier sense (MII_CRS). In half-duplex operation, the MII_CRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is deasserted when both transmit and receive are idle. This signal is not necessarily synchronous to MII_TXCLK nor MII_RXCLK.<br><br>In full-duplex operation, the MII_CRS pin should be held low.                                                                                                                                                                                                                                                        |
| MII_RXCLK    | I    | Receive clock (MII_RXCLK). The receive clock is a continuous clock that provides the timing reference for receive operations. The MII_RXD, MII_RXDV, and MII_RXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.                                                                                                                                                                                                                                                                                                               |
| MII_RXD[3-0] | I    | Receive data (MII_RXD). The receive data pins are a collection of 4 data signals comprising 4 bits of data. MRDX0 is the least-significant bit (LSB). The signals are synchronized by MII_RXCLK and valid only when MII_RXDV is asserted.                                                                                                                                                                                                                                                                                                                                                                               |
| MII_RXDV     | I    | Receive data valid (MII_RXDV). The receive data valid signal indicates that the MII_RXD pins are generating nibble data for use by the EMAC. It is driven synchronously to MII_RXCLK.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| MII_RXER     | I    | Receive error (MII_RXER). The receive error signal is asserted for one or more MII_RXCLK periods to indicate that an error was detected in the received frame. This is meaningful only during data reception when MII_RXDV is active.                                                                                                                                                                                                                                                                                                                                                                                   |
| MDIO_CLK     | O    | Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin. The frequency of this clock is controlled by the CLKDIV bits in the MDIO control register (CONTROL).                                                                                                                                                                                                                                                                                                                                     |

**Table 32-1. EMAC and MDIO Signals for MII Interface (continued)**

| Signal | Type | Description                                                                                                                                                                                                                                                                                                                                                       |
|--------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MDIO_D | I/O  | Management data input output (MDIO_D). The MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations. |

### 32.2.3.2 Reduced Media Independent Interface (RMII) Connections

Figure 32-3 shows a device with integrated EMAC and MDIO interfaced via a RMII connection in a typical system.

The individual EMAC and MDIO signals for the RMII interface are summarized in Table 32-2. For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

**Figure 32-3. Ethernet Configuration—RMII Connections**

**Table 32-2. EMAC and MDIO Signals for RMII Interface**

| Signal          | Type | Description                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RMII_TXD[1-0]   | O    | Transmit data (RMII_TXD). The transmit data pins are a collection of 2 bits of data. RMTDX0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_TXEN is asserted.                                                                                                                                        |
| RMII_TXEN       | O    | Transmit enable (RMII_TXEN). The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK.                                                                                                                                                                                     |
| RMII_MHZ_50_CLK | I    | RMII reference clock (RMII_MHZ_50_CLK). The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz.                                                                                                                                                                                                      |
| RMII_RXD[1-0]   | I    | Receive data (RMII_RXD). The receive data pins are a collection of 2 bits of data. RMRDX0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_CRS_DV is asserted and RMII_RXER is deasserted.                                                                                                            |
| RMII_CRS_DV     | I    | Carrier sense/receive data valid (RMII_CRS_DV). Multiplexed signal between carrier sense and receive data valid.                                                                                                                                                                                                                                                  |
| RMII_RXER       | I    | Receive error (RMII_RXER). The receive error signal is asserted to indicate that an error was detected in the received frame.                                                                                                                                                                                                                                     |
| MDIO_CLK        | O    | Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin. The frequency of this clock is controlled by the CLKDIV bits in the MDIO control register (CONTROL).                                                                               |
| MDIO_D          | I/O  | Management data input output (MDIO_D). The MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations. |

### 32.2.4 MII / RMII Signal Multiplexing Control

Each of the MII and RMII interface signals are multiplexed with other functions on this microcontroller. The application must configure the control registers in the I/O multiplexing module in order to enable the MII/RMII functionality on the corresponding I/Os. [Table 32-3](#) shows the byte to be configured to enable the MDIO functions. [Table 32-4](#) shows the byte to be configured to enable the MII or RMII functions. Please refer the I/O Multiplexing Module chapter of the technical reference manual for more details on the procedure to configure the PINMMR registers.

**Table 32-3. MDIO Multiplexing Control**

| MDIO Signal Name | Control for Selecting EMAC / MDIO Signal |
|------------------|------------------------------------------|
| MDIO_CLK         | PINMMR7 [15:8] = 0b00000100              |
| MDIO_D           | PINMMR8 [15:8] = 0b00000100              |

**Table 32-4. MII / RMII Multiplexing Control**

| MII / RMII Signal Name     | Control for Selecting MII Signal | Control for Selecting RMII Signal |
|----------------------------|----------------------------------|-----------------------------------|
| MII_TXCLK                  | PINMMR17 [7:0] = 0b00000010      | -                                 |
| MII_TXD[3]                 | PINMMR14 [7:0] = 0b00000100      | -                                 |
| MII_TXD[2]                 | PINMMR13 [31:24] = 0b00000100    | -                                 |
| MII_TXD[1] / RMII_TXD[1]   | PINMMR13 [15:8] = 0b00000100     | PINMMR13 [15:8] = 0b00001000      |
| MII_TXD[0] / RMII_TXD[0]   | PINMMR13 [7:0] = 0b00000100      | PINMMR13 [7:0] = 0b00001000       |
| MII_TXEN / RMII_TXEN       | PINMMR13 [23:16] = 0b00000100    | PINMMR13 [23:16] = 0b00001000     |
| MII_COL                    | PINMMR20 [23:16] = 0b00000100    | -                                 |
| MII_CRS / RMII_CRSDV       | PINMMR17 [23:16] = 0b00000010    | PINMMR17 [23:16] = 0b00000100     |
| MII_RXCLK / RMII_50MHZ_CLK | PINMMR14 [15:8] = 0b00000010     | PINMMR14 [15:8] = 0b00000100      |
| MII_RXD[3]                 | PINMMR12 [31:24] = 0b00000100    | -                                 |
| MII_RXD[2]                 | PINMMR12 [23:16] = 0b00000100    | -                                 |
| MII_RXD[1] / RMII_RXD[1]   | PINMMR12 [7:0] = 0b00000010      | PINMMR12 [7:0] = 0b00000100       |
| MII_RXD[0] / RMII_RXD[0]   | PINMMR11 [31:24] = 0b00000100    | PINMMR11 [31:24] = 0b00001000     |
| MII_RXDV                   | PINMMR19 [15:8] = 0b00000010     | -                                 |
| MII_RXER / RMII_RXER       | PINMMR10 [7:0] = 0b00000010      | PINMMR10 [7:0] = 0b00000100       |

### 32.2.5 Ethernet Protocol Overview

A brief overview of the Ethernet protocol is given in the following subsections. See the IEEE 802.3 standard document for in-depth information on the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method.

#### 32.2.5.1 Ethernet Frame Format

All the Ethernet technologies use the same frame structure. The format of an Ethernet frame is shown in [Figure 32-4](#) and described in [Table 32-5](#). The Ethernet packet, which is the collection of bytes representing the data portion of a single Ethernet frame on the wire, is shown outlined in bold. The Ethernet frames are of variable lengths, with no frame smaller than 64 bytes or larger than RXMAXLEN bytes (header, data, and CRC).

**Figure 32-4. Ethernet Frame Format**

Legend: SFD=Start Frame Delimeter; FCS=Frame Check Sequence (CRC)

**Table 32-5. Ethernet Frame Description**

| Field       | Bytes                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Preamble    | 7                        | Preamble. These 7 bytes have a fixed value of 55h and serve to wake up the receiving EMAC ports and to synchronize their clocks to that of the sender's clock.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| SFD         | 1                        | Start of Frame Delimiter. This field with a value of 5Dh immediately follows the preamble pattern and indicates the start of important data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Destination | 6                        | Destination address. This field contains the Ethernet MAC address of the EMAC port for which the frame is intended. It may be an individual or multicast (including broadcast) address. When the destination EMAC port receives an Ethernet frame with a destination address that does not match any of its MAC physical addresses, and no promiscuous, multicast or broadcast channel is enabled, it discards the frame.                                                                                                                                                                                                        |
| Source      | 6                        | Source address. This field contains the MAC address of the Ethernet port that transmits the frame to the Local Area Network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Len         | 2                        | Length/Type field. The length field indicates the number of EMAC client data bytes contained in the subsequent data field of the frame. This field can also be used to identify the type of data the frame is carrying.                                                                                                                                                                                                                                                                                                                                                                                                          |
| Data        | 46 to<br>(RXMAXLEN - 18) | Data field. This field carries the datagram containing the upper layer protocol frame, that is, IP layer datagram. The maximum transfer unit (MTU) of Ethernet is (RXMAXLEN - 18) bytes. This means that if the upper layer protocol datagram exceeds (RXMAXLEN - 18) bytes, then the host has to fragment the datagram and send it in multiple Ethernet packets. The minimum size of the data field is 46 bytes. This means that if the upper layer datagram is less than 46 bytes, the data field has to be extended to 46 bytes by appending extra bits after the data field, but prior to calculating and appending the FCS. |
| FCS         | 4                        | Frame Check Sequence. A cyclic redundancy check (CRC) is used by the transmit and receive algorithms to generate a CRC value for the FCS field. The frame check sequence covers the 60 to 1514 bytes of the packet data. Note that this 4-byte field may or may not be included as part of the packet data, depending on how the EMAC is configured.                                                                                                                                                                                                                                                                             |

### 32.2.5.2 Ethernet's Multiple Access Protocol

Nodes in an Ethernet Local Area Network are interconnected by a broadcast channel -- when an EMAC port transmits a frame, all the adapters on the local network receive the frame. Carrier Sense Multiple Access with Collision Detection (CSMA/CD) algorithms are used when the EMAC operates in half-duplex mode. When operating in full-duplex mode, there is no contention for use of a shared medium because there are exactly two ports on the local network.

Each port runs the CSMA/CD protocol without explicit coordination with the other ports on the Ethernet network. Within a specific port, the CSMA/CD protocol works as follows:

1. The port obtains data from upper layer protocols at its node, prepares an Ethernet frame, and puts the frame in a buffer.
2. If the port senses that the medium is idle, it starts to transmit the frame. If the port senses that the transmission medium is busy, it waits until it no longer senses energy (plus an Inter-Packet Gap time) and then starts to transmit the frame.
3. While transmitting, the port monitors for the presence of signal energy coming from other ports. If the port transmits the entire frame without detecting signal energy from other Ethernet devices, the port is done with the frame.
4. If the port detects signal energy from other ports while transmitting, it stops transmitting its frame and instead transmits a 48-bit jam signal.
5. After transmitting the jam signal, the port enters an exponential backoff phase. If a data frame encounters back-to-back collisions, the port chooses a random value that is dependent on the number of collisions. The port then waits an amount of time that is a multiple of this random value and returns to step 2.

### 32.2.6 Programming Interface

#### 32.2.6.1 Packet Buffer Descriptors

The buffer descriptor is a central part of the EMAC module and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data. The basic descriptor format is shown in [Figure 32-5](#) and described in [Table 32-6](#).

For example, consider three packets to be transmitted: Packet A is a single fragment (60 bytes), Packet B is fragmented over three buffers (1514 bytes total), and Packet C is a single fragment (1514 bytes). The linked list of descriptors to describe these three packets is shown in [Figure 32-6](#).

**Figure 32-5. Basic Descriptor Format**

| Word<br>Offset | Bit Fields              |               |
|----------------|-------------------------|---------------|
|                | 31                      | 0             |
| 0              | Next Descriptor Pointer |               |
| 1              | Buffer Pointer          |               |
| 2              | Buffer Offset           | Buffer Length |
| 3              | Flags                   | Packet Length |

**Table 32-6. Basic Descriptor Description**

| Word Offset | Field                   | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | Next Descriptor Pointer | The next descriptor pointer is used to create a single linked list of descriptors. Each descriptor describes a packet or a packet fragment. When a descriptor points to a single buffer packet or the first fragment of a packet, the start of packet (SOP) flag is set in the flags field. When a descriptor points to a single buffer packet or the last fragment of a packet, the end of packet (EOP) flag is set. When a packet is fragmented, each fragment must have its own descriptor and appear sequentially in the descriptor linked list. |
| 1           | Buffer Pointer          | The buffer pointer refers to the actual memory buffer that contains packet data during transmit operations, or is an empty buffer ready to receive packet data during receive operations.                                                                                                                                                                                                                                                                                                                                                            |
| 2           | Buffer Offset           | The buffer offset is the offset from the start of the packet buffer to the first byte of valid data. This field only has meaning when the buffer descriptor points to a buffer that actually contains data.                                                                                                                                                                                                                                                                                                                                          |
|             | Buffer Length           | The buffer length is the actual number of valid packet data bytes stored in the buffer. If the buffer is empty and waiting to receive data, this field represents the size of the empty buffer.                                                                                                                                                                                                                                                                                                                                                      |
| 3           | Flags                   | The flags field contains more information about the buffer, such as, is it the first fragment in a packet (SOP), the last fragment in a packet (EOP), or contains an entire contiguous Ethernet packet (both SOP and EOP). The flags are described in <a href="#">Section 32.2.6.4</a> and <a href="#">Section 32.2.6.5</a> .                                                                                                                                                                                                                        |
|             | Packet Length           | The packet length only has meaning for buffers that both contain data and are the start of a new packet (SOP). In the case of SOP descriptors, the packet length field contains the length of the entire Ethernet packet, regardless if it is contained in a single buffer or fragmented over several buffers.                                                                                                                                                                                                                                       |

**Figure 32-6. Typical Descriptor Linked List**

### 32.2.6.2 Transmit and Receive Descriptor Queues

The EMAC module processes descriptors in linked lists as discussed in [Section 32.2.6.1](#). The lists used by the EMAC are maintained by the application software through the use of the head descriptor pointer registers (HDP). The EMAC supports eight channels for transmit and eight channels for receive. The corresponding head descriptor pointers are:

- TX $n$ HDP - Transmit Channel  $n$  DMA Head Descriptor Pointer Register
- RX $n$ HDP - Receive Channel  $n$  DMA Head Descriptor Pointer Register

After an EMAC reset and before enabling the EMAC for send and receive, all 16 head descriptor pointer registers must be initialized to 0.

The EMAC uses a simple system to determine if a descriptor is currently owned by the EMAC or by the application software. There is a flag in the buffer descriptor flags called OWNER. When this flag is set, the packet that is referenced by the descriptor is considered to be owned by the EMAC. Note that ownership is done on a packet based granularity, not on descriptor granularity, so only SOP descriptors make use of the OWNER flag. As packets are processed, the EMAC patches the SOP descriptor of the corresponding packet and clears the OWNER flag. This is an indication that the EMAC has finished processing all descriptors up to and including the first with the EOP flag set, indicating the end of the packet (note this may only be one descriptor with both the SOP and EOP flags set).

To add a descriptor or a linked list of descriptors to an EMAC descriptor queue for the first time, the software application simply writes the pointer to the descriptor or first descriptor of a list to the corresponding HDP register. Note that the last descriptor in the list must have its "next" pointer cleared to 0. This is the only way the EMAC has of detecting the end of the list. Therefore, in the case where only a single descriptor is added, its "next descriptor" pointer must be initialized to 0.

The HDP must never be written to while a list is active. To add additional descriptors to a descriptor list already owned by the EMAC, the NULL "next" pointer of the last descriptor of the previous list is patched with a pointer to the first descriptor of the new list. The list of new descriptors to be appended to the existing list must itself be NULL terminated before the pointer patch is performed.

There is a potential race condition where the EMAC may read the "next" pointer of a descriptor as NULL in the instant before an application appends additional descriptors to the list by patching the pointer. This case is handled by the software application always examining the buffer descriptor flags of all EOP packets, looking for a special flag called end of queue (EOQ). The EOQ flag is set by the EMAC on the last descriptor of a packet when the descriptor's "next" pointer is NULL. This is the way the EMAC indicates to the software application that it believes it has reached the end of the list. When the software application sees the EOQ flag set, the application may at that time submit the new list, or the portion of the appended list that was missed by writing the new list pointer to the same HDP that started the process.

This process applies when adding packets to a transmit list, and empty buffers to a receive list.

### 32.2.6.3 Transmit and Receive EMAC Interrupts

The EMAC processes descriptors in linked list chains as discussed in [Section 32.2.6.1](#), using the linked list queue mechanism discussed in [Section 32.2.6.2](#).

The EMAC synchronizes descriptor list processing through the use of interrupts to the software application. The interrupts are controlled by the application using the interrupt masks, global interrupt enable, and the completion pointer register (CP). The CP is also called the interrupt acknowledge register.

The EMAC supports eight channels for transmit and eight channels for receive. The corresponding completion pointer registers are:

- TX $n$ CP - Transmit Channel  $n$  Completion Pointer (Interrupt Acknowledge) Register
- RX $n$ CP - Receive Channel  $n$  Completion Pointer (Interrupt Acknowledge) Register

These registers serve two purposes. When read, they return the pointer to the last descriptor that the EMAC has processed. When written by the software application, the value represents the last descriptor processed by the software application. When these two values do not match, the interrupt is active.

Interrupts in the EMAC control module are routed to the Vectored Interrupt Manager (VIM) as four separate interrupt requests. The interrupt configuration determines whether or not an active interrupt request actually interrupts the CPU. In general the following settings are required for basic EMAC transmit and receive interrupts:

1. EMAC transmit and receive interrupts are enabled by setting the mask registers RXINTMASKSET and TXINTMASKSET
2. Global interrupts are set in the EMAC control module: C0RXEN and C0TXEN
3. The VIM is configured to accept C0\_RX\_PULSE and C0\_TX\_PULSE interrupts from the EMAC control module
4. The normal mode (IRQ) interrupts are enabled in the Cortex-R4F CPU

Whether or not the interrupt is enabled, the current state of the receive or transmit channel interrupt can be examined directly by the software application reading the EMAC receive interrupt status (unmasked) register (RXINTSTATRAW) and transmit interrupt status (unmasked) register (TXINTSTATRAW).

After servicing transmit or receive interrupts, the application software must acknowledge both the EMAC and EMAC control module interrupts.

EMAC interrupts are acknowledged when the application software updates the value of TX $n$ CP or RX $n$ CP with a value that matches the internal value kept by the EMAC. This mechanism ensures that the application software never misses an EMAC interrupt because the interrupt acknowledgment is tied directly to the buffer descriptor processing.

EMAC control module interrupts are acknowledged when the application software writes the appropriate C0TX or C0RX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). The MACEOIVECTOR behaves as an interrupt pulse interlock -- once the EMAC control module has issued an interrupt pulse to the CPU, it will not generate further pulses of the same type until the original pulse has been acknowledged.

### 32.2.6.4 Transmit Buffer Descriptor Format

A transmit (TX) buffer descriptor ([Figure 32-7](#)) is a contiguous block of four 32-bit data words aligned on a 32-bit boundary that describes a packet or a packet fragment. [Example 32-1](#) shows the transmit buffer descriptor described by a C structure.

**Figure 32-7. Transmit Buffer Descriptor Format**

**Example 32-1. Transmit Buffer Descriptor in C Structure Format**

```

/*
// EMAC Descriptor
//
// The following is the format of a single buffer descriptor
// on the EMAC.
*/
typedef struct _EMAC_Desc {
    struct _EMAC_Desc *pNext; /* Pointer to next descriptor in chain */
    Uint8 *pBuffer; /* Pointer to data buffer */
    Uint32 BufOffLen; /* Buffer Offset(MSW) and Length(LSW) */
    Uint32 PktFlgLen; /* Packet Flags(MSW) and Length(LSW) */
} EMAC_Desc;

/* Packet Flags */
#define EMAC_DSC_FLAG_SOP 0x80000000u
#define EMAC_DSC_FLAG_EOP 0x40000000u
#define EMAC_DSC_FLAG_OWNER 0x20000000u
#define EMAC_DSC_FLAG_EOQ 0x10000000u
#define EMAC_DSC_FLAG_TDOWNCMPLT 0x08000000u
#define EMAC_DSC_FLAG_PASSCRC 0x04000000u

```

#### **32.2.6.4.1 Next Descriptor Pointer**

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

#### **32.2.6.4.2 Buffer Pointer**

The buffer pointer is the byte-aligned memory address of the memory buffer associated with the buffer descriptor. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

#### **32.2.6.4.3 Buffer Offset**

This 16-bit field indicates how many unused bytes are at the start of the buffer. For example, a value of 0000h indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer, while a value of 000Fh indicates that the first 15 bytes of the buffer are to be ignored by the EMAC and that valid buffer data starts on byte 16 of the buffer. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC.

Note that this value is only checked on the first descriptor of a given packet (where the start of packet (SOP) flag is set). It can not be used to specify the offset of subsequent packet fragments. Also, since the buffer pointer may point to any byte-aligned address, this field may be entirely superfluous, depending on the device driver architecture.

The range of legal values for this field is 0 to (Buffer Length – 1).

#### **32.2.6.4.4 Buffer Length**

This 16-bit field indicates how many valid data bytes are in the buffer. On single fragment packets, this value is also the total length of the packet data to be transmitted. If the buffer offset field is used, the offset bytes are not counted as part of this length. This length counts only valid data bytes. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC.

#### **32.2.6.4.5 Packet Length**

This 16-bit field specifies the number of data bytes in the entire packet. Any leading buffer offset bytes are not included. The sum of the buffer length fields of each of the packet's fragments (if more than one) must be equal to the packet length. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC. This value is only checked on the first descriptor of a given packet (where the start of packet (SOP) flag is set).

#### **32.2.6.4.6 Start of Packet (SOP) Flag**

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

#### **32.2.6.4.7 End of Packet (EOP) Flag**

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

#### **32.2.6.4.8 Ownership (OWNER) Flag**

When set, this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

#### **32.2.6.4.9 End of Queue (EOQ) Flag**

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

#### **32.2.6.4.10 Teardown Complete (TDOWNCMPLT) Flag**

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission.

Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

#### **32.2.6.4.11 Pass CRC (PASSCRC) Flag**

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC.

When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

### 32.2.6.5 Receive Buffer Descriptor Format

A receive (RX) buffer descriptor ([Figure 32-8](#)) is a contiguous block of four 32-bit data words aligned on a 32-bit boundary that describes a packet or a packet fragment. [Example 32-2](#) shows the receive buffer descriptor described by a C structure.

#### 32.2.6.5.1 Next Descriptor Pointer

This pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the receive queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active receive list. This pointer is not altered by the EMAC.

The value of pNext should never be altered once the descriptor is in an active receive queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more empty buffers can be added to the pool, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the receiver will halt the receive channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

#### 32.2.6.5.2 Buffer Pointer

The buffer pointer is the byte-aligned memory address of the memory buffer associated with the buffer descriptor. The software application must set this value prior to adding the descriptor to the active receive list. This pointer is not altered by the EMAC.

**Figure 32-8. Receive Buffer Descriptor Format**

### Example 32-2. Receive Buffer Descriptor in C Structure Format

```

/*
// EMAC Descriptor
//
// The following is the format of a single buffer descriptor
// on the EMAC.
*/
typedef struct _EMAC_Desc {
    struct _EMAC_Desc *pNext; /* Pointer to next descriptor in chain */
    Uint8 *pBuffer; /* Pointer to data buffer */
    Uint32 BufOffLen; /* Buffer Offset(MSW) and Length(LSW) */
    Uint32 PktFlgLen; /* Packet Flags(MSW) and Length(LSW) */
} EMAC_Desc;

/* Packet Flags */
#define EMAC_DSC_FLAG_SOP 0x80000000u
#define EMAC_DSC_FLAG_EOP 0x40000000u
#define EMAC_DSC_FLAG_OWNER 0x20000000u
#define EMAC_DSC_FLAG_EOQ 0x10000000u
#define EMAC_DSC_FLAG_TDOWNCMPLT 0x08000000u
#define EMAC_DSC_FLAG_PASSCRC 0x04000000u
#define EMAC_DSC_FLAG_JABBER 0x02000000u
#define EMAC_DSC_FLAG_OVERSIZE 0x01000000u
#define EMAC_DSC_FLAG_FRAGMENT 0x00800000u
#define EMAC_DSC_FLAG_UNDERSIZED 0x00400000u
#define EMAC_DSC_FLAG_CONTROL 0x00200000u
#define EMAC_DSC_FLAG_OVERRUN 0x00100000u
#define EMAC_DSC_FLAG_CODEERROR 0x00080000u
#define EMAC_DSC_FLAG_ALIGNERROR 0x00040000u
#define EMAC_DSC_FLAG_CRCERROR 0x00020000u
#define EMAC_DSC_FLAG_NOMATCH 0x00010000u

```

#### 32.2.6.5.3 Buffer Offset

This 16-bit field must be initialized to zero by the software application before adding the descriptor to a receive queue.

Whether or not this field is updated depends on the setting of the RXBUFFEROFFSET register. When the offset register is set to a non-zero value, the received packet is written to the packet buffer at an offset given by the value of the register, and this value is also written to the buffer offset field of the descriptor.

When a packet is fragmented over multiple buffers because it does not fit in the first buffer supplied, the buffer offset only applies to the first buffer in the list, which is where the start of packet (SOP) flag is set in the corresponding buffer descriptor. In other words, the buffer offset field is only updated by the EMAC on SOP descriptors.

The range of legal values for the BUFFEROFFSET register is 0 to (Buffer Length – 1) for the smallest value of buffer length for all descriptors in the list.

#### 32.2.6.5.4 Buffer Length

This 16-bit field is used for two purposes:

- Before the descriptor is first placed on the receive queue by the application software, the buffer length field is first initialized by the software to have the physical size of the empty data buffer pointed to by the buffer pointer field.
- After the empty buffer has been processed by the EMAC and filled with received data bytes, the buffer length field is updated by the EMAC to reflect the actual number of valid data bytes written to the buffer.

#### 32.2.6.5.5 Packet Length

This 16-bit field specifies the number of data bytes in the entire packet. This value is initialized to zero by the software application for empty packet buffers. The value is filled in by the EMAC on the first buffer used for a given packet. This is signified by the EMAC setting a start of packet (SOP) flag. The packet length is set by the EMAC on all SOP buffer descriptors.

#### 32.2.6.5.6 Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

#### 32.2.6.5.7 End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

#### 32.2.6.5.8 Ownership (OWNER) Flag

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

#### 32.2.6.5.9 End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

#### 32.2.6.5.10 Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

**32.2.6.5.11 Pass CRC (PASSCRC) Flag**

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

**32.2.6.5.12 Jabber Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

**32.2.6.5.13 Oversize Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an oversized frame and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**32.2.6.5.14 Fragment Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**32.2.6.5.15 Undersized Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is undersized and was not discarded because the RXCSFEN bit was set in the RXMBPENABLE.

**32.2.6.5.16 Control Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RXCMFEN bit was set in the RXMBPENABLE.

**32.2.6.5.17 Overrun Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

**32.2.6.5.18 Code Error (CODEERROR) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained a code error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**32.2.6.5.19 Alignment Error (ALIGNERROR) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained an alignment error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**32.2.6.5.20 CRC Error (CRCERROR) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained a CRC error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**32.2.6.5.21 No Match (NOMATCH) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet did not pass any of the EMAC's address match criteria and was not discarded because the RXCAFEN bit was set in the RXMBPENABLE. Although the packet is a valid Ethernet data packet, it was only received because the EMAC is in promiscuous mode.

### 32.2.7 EMAC Control Module

The EMAC control module (Figure 32-9) interfaces the EMAC and MDIO modules to the rest of the system, and also provides a local memory space to hold EMAC packet buffer descriptors. Local memory is used to help avoid contention with device memory spaces. Other functions include the bus arbiter, and interrupt logic control.

**Figure 32-9. EMAC Control Module Block Diagram**

#### 32.2.7.1 Internal Memory

The EMAC control module includes 8K bytes of internal memory (CPPI buffer descriptor memory). The internal memory block is essential for allowing the EMAC to operate more independently of the CPU. It also prevents memory underflow conditions when the EMAC issues read or write requests to descriptor memory. (Memory accesses to read or write the actual Ethernet packet data are protected by the EMAC's internal FIFOs).

A descriptor is a 16-byte memory structure that holds information about a single Ethernet packet buffer, which may contain a full or partial Ethernet packet. Thus with the 8K memory block provided for descriptor storage, the EMAC module can send and received up to a combined 512 packets before it needs to be serviced by application or driver software.

#### 32.2.7.2 Bus Arbiter

The EMAC control module bus arbiter operates transparently to the rest of the system. It is used:

- To arbitrate between the CPU and EMAC buses for access to internal descriptor memory.
- To arbitrate between internal EMAC buses for access to system memory.

### 32.2.7.3 Interrupt Control

Interrupt conditions generated by the EMAC and MDIO modules are combined into four interrupt signals that are routed to the Vectored Interrupt Manager (VIM); the VIM then relays the interrupt signals to the CPU. The EMAC control module uses two sets of registers to control the interrupt signals to the CPU:

- C0RXTHRESHEN, C0RXEN, C0TXEN, and C0MISCEN registers enable the pulse signals that are mapped to the VIM
- INTCONTROL, C0RXIMAX, and C0TXIMAX registers enable interrupt pacing to limit the number of interrupt pulses generated per millisecond

Interrupts must be acknowledged by writing the appropriate value to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). The MACEOIVECTOR behaves as an interrupt pulse interlock -- once the EMAC control module has issued an interrupt pulse to the CPU, it will not generate further pulses of the same type until the original pulse has been acknowledged.

### 32.2.8 MDIO Module

The MDIO module is used to manage up to 32 physical layer (PHY) devices connected to the Ethernet Media Access Controller (EMAC). The device supports a single PHY being connected to the EMAC at any given time. The MDIO module is designed to allow almost transparent operation of the MDIO interface with little maintenance from the CPU.

The MDIO module continuously polls 32 MDIO addresses in order to enumerate all PHY devices in the system. Once a PHY device has been detected, the MDIO module reads the MDIO PHY link status register (LINK) to monitor the PHY link state. Link change events are stored in the MDIO module, which can interrupt the CPU. This storing of the events allows the CPU to poll the link status of the PHY device without continuously performing MDIO module accesses. However, when the CPU must access the MDIO module for configuration and negotiation, the MDIO module performs the MDIO read or write operation independent of the CPU. This independent operation allows the processor to poll for completion or interrupt the CPU once the operation has completed.

The MDIO module does not support the "Clause 45" interface.

#### 32.2.8.1 MDIO Module Components

The MDIO module ([Figure 32-10](#)) interfaces to the PHY components through two MDIO pins (MDIO\_CLK and MDIO), and to the CPU through the EMAC control module and the configuration bus. The MDIO module consists of the following logical components:

- MDIO clock generator
- Global PHY detection and link state monitoring
- Active PHY monitoring
- PHY register user access

**Figure 32-10. MDIO Module Block Diagram**

### 32.2.8.1.1 MDIO Clock Generator

The MDIO clock generator controls the MDIO clock based on a divide-down of the VCLK3 peripheral clock in the EMAC control module. The MDIO clock is specified to run up to 2.5 MHz, although typical operation would be 1.0 MHz. Since the VCLK3 peripheral clock frequency is configurable, the application software or driver controls the divide-down amount. See the device datasheet for peripheral clock speed specifications.

### 32.2.8.1.2 Global PHY Detection and Link State Monitoring

The MDIO module continuously polls all 32 MDIO addresses in order to enumerate the PHY devices in the system. The module tracks whether or not a PHY on a particular address has responded, and whether or not the PHY currently has a link. Using this information allows the software application to quickly determine which MDIO address the PHY is using.

### 32.2.8.1.3 Active PHY Monitoring

Once a PHY candidate has been selected for use, the MDIO module transparently monitors its link state by reading the MDIO PHY link status register (LINK). Link change events are stored on the MDIO device and can optionally interrupt the CPU. This allows the system to poll the link status of the PHY device without continuously performing costly MDIO accesses.

### 32.2.8.1.4 PHY Register User Access

When the CPU must access MDIO for configuration and negotiation, the PHY access module performs the actual MDIO read or write operation independent of the CPU. This allows the CPU to poll for completion or receive an interrupt when the read or write operation has been performed. The user access registers USERACCESS<sub>n</sub> allows the software to submit the access requests for the PHY connected to the device.

### 32.2.8.2 MDIO Module Operational Overview

The MDIO module implements the 802.3 serial management interface to interrogate and control an Ethernet PHY, using a shared two-wired bus. It separately performs autodetection and records the current link status of up to 32 PHYs, polling all 32 MDIO addresses.

Application software uses the MDIO module to configure the autonegotiation parameters of the PHY attached to the EMAC, retrieve the negotiation results, and configure required parameters in the EMAC.

In this device, the Ethernet PHY attached to the system can be directly controlled and queried. The Media Independent Interface (MII) address of this PHY device is specified in one of the PHYADRMON bits in the MDIO user PHY select register (USERPHYSEL<sub>n</sub>). The MDIO module can be programmed to trigger a CPU interrupt on a PHY link change event, by setting the LINKINTENB bit in USERPHYSEL<sub>n</sub>. Reads and writes to registers in this PHY device are performed using the MDIO user access register (USERACCESS<sub>n</sub>).

The MDIO module powers-up in an idle state until specifically enabled by setting the ENABLE bit in the MDIO control register (CONTROL). At this time, the MDIO clock divider and preamble mode selection are also configured. The MDIO preamble is enabled by default, but can be disabled when the connected PHY does not require it. Once the MDIO module is enabled, the MDIO interface state machine continuously polls the PHY link status (by reading the generic status register) of all possible 32 PHY addresses and records the results in the MDIO PHY alive status register (ALIVE) and MDIO PHY link status register (LINK). The corresponding bit for the connected PHY (0-31) is set in ALIVE, if the PHY responded to the read request. The corresponding bit is set in LINK, if the PHY responded and also is currently linked. In addition, any PHY register read transactions initiated by the application software using USERACCESS<sub>n</sub> causes ALIVE to be updated.

The USERPHYSEL<sub>n</sub> is used to track the link status of the connected PHY address. A change in the link status of the PHY being monitored sets the appropriate bit in the MDIO link status change interrupt registers (LINKINTRAW and LINKINTMASKED), if enabled by the LINKINTENB bit in USERPHYSEL<sub>n</sub>.

While the MDIO module is enabled, the host issues a read or write transaction over the MII management interface using the DATA, PHYADR, REGADR, and WRITE bits in USERACCESS<sub>n</sub>. When the application sets the GO bit in USERACCESS<sub>n</sub>, the MDIO module begins the transaction without any further intervention from the CPU. Upon completion, the MDIO module clears the GO bit and sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS<sub>n</sub> used. The corresponding USERINTMASKED bit (0 or 1) in the MDIO user command complete interrupt register (USERINTMASKED) may also be set, depending on the mask setting configured in the MDIO user command complete interrupt mask set register (USERINTMASKSET) and the MDIO user interrupt mask clear register (USERINTMASKCLEAR).

A round-robin arbitration scheme is used to schedule transactions that may be queued using both USERACCESS<sub>0</sub> and USERACCESS<sub>1</sub>. The application software must check the status of the GO bit in USERACCESS<sub>n</sub> before initiating a new transaction, to ensure that the previous transaction has completed. The application software can use the ACK bit in USERACCESS<sub>n</sub> to determine the status of a read transaction.

### 32.2.8.2.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO control register (CONTROL).
2. Enable the MDIO module by setting the ENABLE bit in CONTROL.
3. The MDIO PHY alive status register (ALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (LINK) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register (USERPHYSEL $n$ ), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) to use the MDIO user access register (USERACCESS $n$ ). Since only one PHY is used in this device, the application software can use one USERACCESS $n$  to trigger a completion interrupt; the other USERACCESS $n$  is not setup.

### 32.2.8.2.2 Writing Data To a PHY Register

The MDIO module includes a user access register (USERACCESS $n$ ) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS $n$ ) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in USERACCESS $n$  corresponding to the PHY and PHY register you want to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in USERACCESS $n$  for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS $n$  used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

### 32.2.8.2.3 Reading Data From a PHY Register

The MDIO module includes a user access register (USERACCESS $n$ ) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS $n$ ) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in USERACCESS $n$  corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in USERACCESS $n$  after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in USERACCESS $n$ . Once the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS $n$  used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

### 32.2.8.2.4 Example of MDIO Register Access Code

The MDIO module uses the MDIO user access register (USERACCESS $n$ ) to access the PHY control registers. Software functions that implement the access process may simply be the following four macros:

- PHYREG\_read( regadr, phyadr )                      Start the process of reading a PHY register
- PHYREG\_write( regadr, phyadr, data )              Start the process of writing a PHY register
- PHYREG\_wait( )                                          Synchronize operation (make sure read/write is idle)
- PHYREG\_waitResults( results )                      Wait for read to complete and return data read

Note that it is not necessary to wait after a write operation, as long as the status is checked before every operation to make sure the MDIO hardware is idle. An alternative approach is to call PHYREG\_wait() after every write, and PHYREG\_waitResults( ) after every read, then the hardware can be assumed to be idle when starting a new operation.

The implementation of these macros using the chip support library (CSL) is shown in [Example 32-3](#) (USERACCESS0 is assumed).

Note that this implementation does not check the ACK bit in USERACCESS $n$  on PHY register reads (does not follow the procedure outlined in [Section 32.2.8.2.3](#)). Since the MDIO PHY alive status register (ALIVE) is used to initially select a PHY, it is assumed that the PHY is acknowledging read operations. It is possible that a PHY could become inactive at a future point in time. An example of this would be a PHY that can have its MDIO addresses changed while the system is running. It is not very likely, but this condition can be tested by periodically checking the PHY state in ALIVE.

### Example 32-3. MDIO Register Access Macros

```
#define PHYREG_read(regadr, phyadr)
    MDIO_REGS->USERACCESS0 =
        CSL_FMK(MDIO_USERACCESS0_G0,1u)           | /
        CSL_FMK(MDIO_USERACCESS0_REGADR,regadr)    | /
        CSL_FMK(MDIO_USERACCESS0_PHYADR,phyadr)
#define PHYREG_write(regadr, phyadr, data)
    MDIO_REGS->USERACCESS0 =
        CSL_FMK(MDIO_USERACCESS0_G0,1u)           | /
        CSL_FMK(MDIO_USERACCESS0_WRITE,1)          | /
        CSL_FMK(MDIO_USERACCESS0_REGADR,regadr)    | /
        CSL_FMK(MDIO_USERACCESS0_PHYADR,phyadr)    | /
        CSL_FMK(MDIO_USERACCESS0_DATA, data)
#define PHYREG_wait()
    while( CSL_FEXT(MDIO_REGS->USERACCESS0,MDIO_USERACCESS0_G0) )
#define PHYREG_waitResults( results ) {
    while( CSL_FEXT(MDIO_REGS->USERACCESS0,MDIO_USERACCESS0_G0) );
    results = CSL_FEXT(MDIO_REGS->USERACCESS0, MDIO_USERACCESS0_DATA); }
```

## 32.2.9 EMAC Module

This section discusses the architecture and basic function of the EMAC module.

### 32.2.9.1 EMAC Module Components

The EMAC module ([Figure 32-11](#)) interfaces to the outside world through the Media Independent Interface (MII) or Reduced Media Independent Interface (RMII). The interface between the EMAC module and the system core is provided through the EMAC control module. The EMAC consists of the following logical components:

- The receive path includes: receive DMA engine, receive FIFO, and MAC receiver
- The transmit path includes: transmit DMA engine, transmit FIFO, and MAC transmitter
- Statistics logic
- State RAM
- Interrupt controller
- Control registers and logic
- Clock and reset logic

**Figure 32-11. EMAC Module Block Diagram**

#### 32.2.9.1.1 Receive DMA Engine

The receive DMA engine is the interface between the receive FIFO and the system core. It interfaces to the CPU through the bus arbiter in the EMAC control module. This DMA engine is totally independent of the device DMA.

#### 32.2.9.1.2 Receive FIFO

The receive FIFO consists of three cells of 64-bytes each and associated control logic. The FIFO buffers receive data in preparation for writing into packet buffers in device memory.

### 32.2.9.1.3 MAC Receiver

The MAC receiver detects and processes incoming network frames, de-frames them, and puts them into the receive FIFO. The MAC receiver also detects errors and passes statistics to the statistics RAM.

### 32.2.9.1.4 Transmit DMA Engine

The transmit DMA engine is the interface between the transmit FIFO and the CPU. It interfaces to the CPU through the bus arbiter in the EMAC control module.

### 32.2.9.1.5 Transmit FIFO

The transmit FIFO consists of three cells of 64-bytes each and associated control logic. The FIFO buffers data in preparation for transmission.

### 32.2.9.1.6 MAC Transmitter

The MAC transmitter formats frame data from the transmit FIFO and transmits the data using the CSMA/CD access protocol. The frame CRC can be automatically appended, if required. The MAC transmitter also detects transmission errors and passes statistics to the statistics registers.

### 32.2.9.1.7 Statistics Logic

The Ethernet statistics are counted and stored in the statistics logic RAM. This statistics RAM keeps track of 36 different Ethernet packet statistics.

### 32.2.9.1.8 State RAM

State RAM contains the head descriptor pointers and completion pointers registers for both transmit and receive channels.

### 32.2.9.1.9 EMAC Interrupt Controller

The interrupt controller contains the interrupt related registers and logic. The 26 raw EMAC interrupts are input to this submodule and masked module interrupts are output.

### 32.2.9.1.10 Control Registers and Logic

The EMAC is controlled by a set of memory-mapped registers. The control logic also signals transmit, receive, and status related interrupts to the CPU through the EMAC control module.

### 32.2.9.1.11 Clock and Reset Logic

The clock and reset submodule generates all the EMAC clocks and resets. For more details on reset capabilities, see [Section 32.2.15.1](#).

## 32.2.9.2 EMAC Module Operational Overview

After reset, initialization, and configuration, the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the state RAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory. The DMA controller writes the packet into the transmit FIFO in bursts of 64-byte cells. When the threshold number of cells, configurable using the TXCELLTHRESH bit in the FIFO control register (FIFOCONTROL), have been written to the transmit FIFO, or a complete packet, whichever is smaller, the MAC transmitter then initiates the packet transmission. The SYNC block transmits the packet over the MII or RMII interfaces in accordance with the 802.3 protocol. Transmit statistics are counted by the statistics block.

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The SYNC submodule receives packets and strips off the Ethernet related protocol. The packet data is input to the MAC receiver, which checks for address match and processes errors. Accepted packets are then written to the receive FIFO in bursts of 64-byte cells. The receive DMA controller then writes the packet data to memory. Receive statistics are counted by the statistics block.

The EMAC module operates independently of the CPU. It is configured and controlled by its register set mapped into device memory. Information about data packets is communicated by use of 16-byte descriptors that are placed in an 8K-byte block of RAM in the EMAC control module (CPPI buffer descriptor memory).

For transmit operations, each 16-byte descriptor describes a packet or packet fragment in the system's internal or external memory. For receive operations, each 16-byte descriptor represents a free packet buffer or buffer fragment. On both transmit and receive, an Ethernet packet is allowed to span one or more memory fragments, represented by one 16-byte descriptor per fragment. In typical operation, there is only one descriptor per receive buffer, but transmit packets may be fragmented, depending on the software architecture.

An interrupt is issued to the CPU whenever a transmit or receive operation has completed. However, it is not necessary for the CPU to service the interrupt while there are additional resources available. In other words, the EMAC continues to receive Ethernet packets until its receive descriptor list has been exhausted. On transmit operations, the transmit descriptors need only be serviced to recover their associated memory buffer. Thus, it is possible to delay servicing of the EMAC interrupt if there are real-time tasks to perform.

Eight channels are supplied for both transmit and receive operations. On transmit, the eight channels represent eight independent transmit queues. The EMAC can be configured to treat these channels as an equal priority "round-robin" queue or as a set of eight fixed-priority queues. On receive, the eight channels represent eight independent receive queues with packet classification. Packets are classified based on the destination MAC address. Each of the eight channels is assigned its own MAC address, enabling the EMAC module to act like eight virtual MAC adapters. Also, specific types of frames can be sent to specific channels. For example, multicast, broadcast, or other (promiscuous, error, etc.), can each be received on a specific receive channel queue.

The EMAC keeps track of 36 different statistics, plus keeps the status of each individual packet in its corresponding packet descriptor.

### **32.2.10 MAC Interface**

The following sections discuss the operation of the Media Independent Interface (MII) and Reduced Media Independent Interface (RMII) in 10 Mbps and 100 Mbps mode. An IEEE 802.3 compliant Ethernet MAC controls the interface.

#### **32.2.10.1 Data Reception**

##### **32.2.10.1.1 Receive Control**

Data received from the PHY is interpreted and output to the EMAC receive FIFO. Interpretation involves detection and removal of the preamble and start-of-frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation. Address detection and frame filtering is performed outside the MAC interface.

##### **32.2.10.1.2 Receive Inter-Frame Interval**

The 802.3 standard requires an interpacket gap (IPG), which is 96 bit times. However, the EMAC can tolerate a reduced IPG of 8 bit times with a correct preamble and start frame delimiter. This interval between frames must comprise (in the following order):

1. An Interpacket Gap (IPG).
2. A 7-byte preamble (all bytes 55h).
3. A 1-byte start of frame delimiter (5Dh).

### 32.2.10.1.3 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the EMAC from further frame reception. Two forms of receive buffer flow control are available:

- Collision-based flow control for half-duplex mode
- IEEE 802.3x pause frames flow control for full-duplex mode

In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control prevents reception of frames on the EMAC until all of the triggering conditions clear, at which time frames may again be received by the EMAC.

Receive flow control is enabled by the RXBUFFERFLOWEN bit in the MAC control register (MACCONTROL). The EMAC is configured for collision or IEEE 802.3X flow control using the FULLDUPLEX bit in MACCONTROL. Receive flow control is triggered when the number of free buffers in any enabled receive channel free buffer count register (RXnFREEBUFFER) is less than or equal to the receive channel flow control threshold register (RXnFLOWTHRESH) value. Receive flow control is independent of receive QOS, except that both use the free buffer values.

#### 32.2.10.1.3.1 Collision-Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the EMAC is operating in half-duplex mode (the FULLDUPLEX bit is cleared in MACCONTROL). When receive flow control is enabled and triggered, the EMAC generates collisions for received frames. The jam sequence transmitted is the 12-byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3h. The jam sequence begins no later than approximately as the source address starts to be received. Note that these forced collisions are not limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm.

Receive flow control does not depend on the value of the incoming frame destination address. A collision is generated for any incoming packet, regardless of the destination address, if any EMAC enabled channel's free buffer register value is less than or equal to the channel's flow threshold value.

#### 32.2.10.1.3.2 IEEE 802.3x-Based Receive Buffer Flow Control

IEEE 802.3x-based receive buffer flow control provides a means of preventing frame reception when the EMAC is operating in full-duplex mode (the FULLDUPLEX bit is set in MACCONTROL). When receive flow control is enabled and triggered, the EMAC transmits a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The EMAC transmits a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle or following the completion of the frame currently being transmitted). The pause frame contains the maximum possible value for the pause time (FFFFh). The EMAC counts the receive pause frame time (decrements FF00h to 0) and retransmits an outgoing pause frame, if the count reaches 0. When the flow control request is removed, the EMAC transmits a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval are received normally (provided the receive FIFO is not full).

Pause frames are transmitted if enabled and triggered, regardless of whether or not the EMAC is observing the pause time period from an incoming pause frame.

The EMAC transmits pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01h.
- The 48-bit source address (set using the MACSRCADDRLO and MACSRCADDRHI registers).
- The 16-bit length/type field containing the value 88.08h.
- The 16-bit pause opcode equal to 00.01h.
- The 16-bit pause time value of FF.FFh. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request have a pause time value of 00.00h.
- Zero padding to 64-byte data length (EMAC transmits only 64-byte pause frames).

- The 32-bit frame-check sequence (CRC word).

All quantities are hexadecimal and are transmitted most-significant byte first. The least-significant bit (LSB) is transferred first in each byte.

If the RXBUFFERFLOWEN bit in MACCONTROL is cleared to 0 while the pause time is nonzero, then the pause time is cleared to 0 and a zero count pause frame is sent.

### 32.2.10.2 Data Transmission

The EMAC passes data to the PHY from the transmit FIFO (when enabled). Data is synchronized to the transmit clock rate. Transmission begins when there are TXCELLTHRESH cells of 64 bytes each, or a complete packet, in the FIFO.

#### 32.2.10.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted), the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full-duplex mode, the carrier sense (MII\_CRD) and collision-sensing (MII\_COL) modes are disabled.

#### 32.2.10.2.2 CRC Insertion

If the SOP buffer descriptor PASSCRC flag is cleared, the EMAC generates and appends a 32-bit Ethernet CRC onto the transmitted data. For the EMAC-generated CRC case, a CRC (or placeholder) at the end of the data is allowed but not required. The buffer byte count value should not include the CRC bytes, if they are present.

If the SOP buffer descriptor PASSCRC flag is set, then the last four bytes of the transmit data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the buffer byte count value. The MAC performs no error checking on the outgoing CRC.

#### 32.2.10.2.3 Adaptive Performance Optimization (APO)

The EMAC incorporates adaptive performance optimization (APO) logic that may be enabled by setting the TXPACE bit in the MAC control register (MACCONTROL). Transmission pacing to enhance performance is enabled when the TXPACE bit is set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions), thereby, increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions, or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision, or excessive collision), the pacing counter is decremented by 1, down to 0.

With pacing enabled, a new frame is permitted to immediately (after one interpacket gap) attempt transmission only if the pacing counter is 0. If the pacing counter is nonzero, the frame is delayed by the pacing delay of approximately four interpacket gap (IPG) delays. APO only affects the IPG preceding the first attempt at transmitting a frame; APO does not affect the back-off algorithm for retransmitted frames.

#### 32.2.10.2.4 Interpacket-Gap (IPG) Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision and MII\_CRD is deasserted within approximately 48 bit times of MII\_TXEN being deasserted, then 96 bit times is measured from MII\_TXEN. If the frame suffered a collision or MII\_CRD is not deasserted until more than approximately 48 bit times after MII\_TXEN is deasserted, then 96 bit times (approximately, but not less) is measured from MII\_CRD.

#### 32.2.10.2.5 Back Off

The EMAC implements the 802.3 binary exponential back-off algorithm.

### 32.2.10.2.6 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the EMAC from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TXFLOWEN bits in the MAC control register (MACCONTROL) are set. Pause frames are not acted upon in half-duplex mode. Pause frame action is taken if enabled, but normally the frame is filtered and not transferred to memory. MAC control frames are transferred to memory, if the RXCMFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) is set. The TXFLOWEN and FULLDUPLEX bits affect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC control frames with an opcode field of 0001h. Incoming pause frames are only acted upon by the EMAC if:

- TXFLOWEN bit is set in MACCONTROL
- The frame's length is 64 to RXMAXLEN bytes inclusive
- The frame contains no CRC error or align/code errors

The pause time value from valid frames is extracted from the two bytes following the opcode. The pause time is loaded into the EMAC transmit pause timer and the transmit pause time period begins. If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- If the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer immediately expires, or
- If the new pause time value is 0, then the transmit pause timer immediately expires, else
- The EMAC transmit pause timer immediately is set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame is discarded).

If the TXFLOWEN bit in MACCONTROL is cleared, then the pause timer immediately expires.

The EMAC does not start the transmission of a new data frame any sooner than 512 bit-times after a pause frame with a nonzero pause time has finished being received (MII\_RXDV going inactive). No transmission begins until the pause timer has expired (the EMAC may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received is completed and unaffected.

Incoming pause frames consist of:

- A 48-bit destination address equal to one of the following:
  - The reserved multicast destination address 01.80.C2.00.00.01h
  - Any EMAC 48-bit unicast address. Pause frames are accepted, regardless of whether the channel is enabled or not.
- The 16-bit length/type field containing the value 88.08h.
- The 48-bit source address of the transmitting device.
- The 16-bit pause opcode equal to 00.01h.
- The 16-bit pause time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities are hexadecimal and are transmitted most-significant byte first. The least-significant bit (LSB) is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The EMAC recognizes any pause frame between 64 bytes and RXMAXLEN bytes in length.

### 32.2.10.2.7 Speed, Duplex, and Pause Frame Support

The MAC operates at 10 Mbps or 100 Mbps, in half-duplex or full-duplex mode, and with or without pause frame support as configured by the host.

### 32.2.11 Packet Receive Operation

#### 32.2.11.1 Receive DMA Host Configuration

To configure the receive DMA for operation the host must:

- Initialize the receive addresses.
- Initialize the receive channel  $n$  DMA head descriptor pointer registers (RX $n$ HDP) to 0.
- Write the MAC address hash  $n$  registers (MACHASH1 and MACHASH2), if multicast addressing is desired.
- If flow control is to be enabled, initialize:
  - the receive channel  $n$  free buffer count registers (RX $n$ FREEBUFFER)
  - the receive channel  $n$  flow control threshold register (RX $n$ FLOWTHRESH)
  - the receive filter low priority frame threshold register (RXFILTERLOWTHRESH)
- Enable the desired receive interrupts using the receive interrupt mask set register (RXINTMASKSET) and the receive interrupt mask clear register (RXINTMASKCLEAR).
- Set the appropriate configuration bits in the MAC control register (MACCONTROL).
- Write the receive buffer offset register (RXBUFFEROFFSET) value (typically zero).
- Setup the receive channel(s) buffer descriptors and initialize RX $n$ HDP.
- Enable the receive DMA controller by setting the RXEN bit in the receive control register (RXCONTROL).
- Configure and enable the receive operation, as desired, in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) and by using the receive unicast set register (RXUNICASTSET) and the receive unicast clear register (RXUNICASTCLEAR).

#### 32.2.11.2 Receive Channel Enabling

Each of the eight receive channels has an enable bit (RXCH $n$ EN) in the receive unicast set register (RXUNICASTSET) that is controlled using RXUNICASTSET and the receive unicast clear register (RXUNICASTCLEAR). The RXCH $n$ EN bits determine whether the given channel is enabled (when set to 1) to receive frames with a matching unicast or multicast destination address.

The RXBROADEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) determines if broadcast frames are enabled or filtered. If broadcast frames are enabled (when set to 1), then they are copied to only a single channel selected by the RXBROADCH bit in RXMBPENABLE.

The RXMULTEN bit in RXMBPENABLE determines if hash matching multicast frames are enabled or filtered. Incoming multicast addresses (group addresses) are hashed into an index in the hash table. If the indexed bit is set then the frame hash matches and will be transferred to the channel selected by the RXMULTCH bit in RXMBPENABLE when multicast frames are enabled. The multicast hash bits are set in the MAC address hash  $n$  registers (MACHASH1 and MACHASH2).

The RXPROMCH bit in RXMBPENABLE selects the promiscuous channel to receive frames selected by the RXCMFEN, RXCSFEN, RXCEFEN, and RXCAFEN bits. These four bits allow reception of MAC control frames, short frames, error frames, and all frames (promiscuous), respectively.

#### 32.2.11.3 Receive Address Matching

All eight MAC addresses corresponding to the eight receive channels share the upper 40 bits. Only the lower byte is unique for each address. All eight receive addresses should be initialized, because pause frames are acted upon regardless of whether a channel is enabled or not.

A MAC address is written by first writing the address number (channel) to be written into the MAC index register (MACINDEX). The upper 32 bits of address are then written to the MAC address high bytes register (MACADDRHI), which is followed by writing the lower 16 bits of address to the MAC address low bytes register (MACADDRLO). Since all eight MAC addresses share the upper 40 bits of address, MACADDRHI needs to be written only the first time (for the first channel configured).

### 32.2.11.4 Hardware Receive QOS Support

Hardware receive quality of service (QOS) is supported, when enabled, by the Tag Protocol Identifier format and the associated Tag Control Information (TCI) format priority field. When the incoming frame length/type value is equal to 81.00h, the EMAC recognizes the frame as an Ethernet Encoded Tag Protocol Type. The two octets immediately following the protocol type contain the 16-bit TCI field. Bits 15-13 of the TCI field contain the received frames priority (0 to 7). The received frame is a low-priority frame, if the priority value is 0 to 3; the received frame is a high-priority frame, if the priority value is 4 to 7. All frames that have a length/type field value not equal to 81.00h are low-priority frames. Received frames that contain priority information are determined by the EMAC as:

- A 48-bit (6 bytes) destination address equal to:
  - The destination station's individual unicast address.
  - The destination station's multicast address (MACHASH1 and MACHASH2).
  - The broadcast address of all ones.
- A 48-byte (6 bytes) source address.
- The 16-bit (2 bytes) length/type field containing the value 81.00h.
- The 16-bit (2 bytes) TCI field with the priority field in the upper 3 bits.
- Data bytes
- The 4 bytes CRC.

The receive filter low priority frame threshold register (RXFILTERLOWTHRESH) and the receive channel *n* free buffer count registers (RXnFREEBUFFER) are used in conjunction with the priority information to implement receive hardware QOS. Low-priority frames are filtered if the number of free buffers (RXnFREEBUFFER) for the frame channel is less than or equal to the filter low threshold (RXFILTERLOWTHRESH) value. Hardware QOS is enabled by the RXQOSEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE).

### 32.2.11.5 Host Free Buffer Tracking

The host must track free buffers for each enabled channel (including unicast, multicast, broadcast, and promiscuous), if receive QOS or receive flow control is used. Disabled channel free buffer values are do not cares. During initialization, the host should write the number of free buffers for each enabled channel to the appropriate receive channel *n* free buffer count registers (RXnFREEBUFFER). The EMAC decrements the appropriate channel's free buffer value for each buffer used. When the host reclaims the frame buffers, the host should write the channel free buffer register with the number of reclaimed buffers (write to increment). There are a maximum of 65,535 free buffers available. RXnFREEBUFFER only needs to be updated by the host if receive QOS or flow control is used.

### 32.2.11.6 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the receive teardown register (RXTEARDOWN). When a teardown command is issued to an enabled receive channel, the following occurs:

- Any current frame in reception completes normally.
- The TDOWNCMPLT flag is set in the next buffer descriptor in the chain, if there is one.
- The channel head descriptor pointer is cleared to 0.
- A receive interrupt for the channel is issued to the host.
- The corresponding receive channel *n* completion pointer register (RXnCP) contains the value FFFF FFFCh.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete (TDOWNCMPLT) buffer descriptor bit. The EMAC does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with an FFFF FFFCh acknowledge value to RXnCP (note that there is no buffer descriptor in this case). Software may read RXnCP to determine if the interrupt was due to a commanded teardown. The read value is FFFF FFFCh, if the interrupt was due to a teardown command.

### 32.2.11.7 Receive Frame Classification

Received frames are proper (good) frames, if they are between 64 bytes and the value in the receive maximum length register (RXMAXLEN) bytes in length (inclusive) and contain no code, align, or CRC errors.

Received frames are long frames, if their frame count exceeds the value in RXMAXLEN. The RXMAXLEN reset (default) value is 5EEh (1518 in decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames; long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames, if their frame count is less than 64 bytes. Short frames that address match and contain no errors are undersized frames; short frames with CRC, code, or alignment errors are fragment frames. If the frame length is less than or equal to 20, then the frame CRC is passed, regardless of whether the RXPASSCRC bit is set or cleared in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE).

A received long packet always contains RXMAXLEN number of bytes transferred to memory (if the RXCEFEN bit is set in RXMBPENABLE), regardless of the value of the RXPASSCRC bit. Following is an example with RXMAXLEN set to 1518:

- If the frame length is 1518, then the packet is not a long packet and there are 1514 or 1518 bytes transferred to memory depending on the value of the RXPASSCRC bit.
- If the frame length is 1519, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last three bytes are the first three CRC bytes.
- If the frame length is 1520, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last two bytes are the first two CRC bytes.
- If the frame length is 1521, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last byte is the first CRC byte.
- If the frame length is 1522, there are 1518 bytes transferred to memory. The last byte is the last data byte.

### 32.2.11.8 Promiscuous Receive Mode

When the promiscuous receive mode is enabled by setting the RXCAFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE), nonaddress matching frames that would normally be filtered are transferred to the promiscuous channel. Address matching frames that would normally be filtered due to errors are transferred to the address match channel when the RXCAFEN and RXCEFEN bits in RXMBPENABLE are set. A frame is considered to be an address matching frame only if it is enabled to be received on a unicast, multicast, or broadcast channel. Frames received to disabled unicast, multicast, or broadcast channels are considered nonaddress matching.

MAC control frames address match only if the RXCMFEN bit in RXMBPENABLE is set. The RXCEFEN and RXCSFEN bits in RXMBPENABLE determine whether error frames are transferred to memory or not, but they do not determine whether error frames are address matching or not. Short frames are a special type of error frames.

A single channel is selected as the promiscuous channel by the RXPROMCH bit in RXMBPENABLE. The promiscuous receive mode is enabled by the RXCMFEN, RXCEFEN, RXCSFEN, and RXCAFEN bits in RXMBPENABLE. [Table 32-7](#) shows the effects of the promiscuous enable bits. Proper frames are frames that are between 64 bytes and the value in the receive maximum length register (RXMAXLEN) bytes in length inclusive and contain no code, align, or CRC errors.

**Table 32-7. Receive Frame Treatment Summary**

| Address Match | RXCAFEN | RXCEFEN | RXCMFEN | RXCSFEN | Receive Frame Treatment                                                                                                                            |
|---------------|---------|---------|---------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 0             | 0       | X       | X       | X       | No frames transferred.                                                                                                                             |
| 0             | 1       | 0       | 0       | 0       | Proper frames transferred to promiscuous channel.                                                                                                  |
| 0             | 1       | 0       | 0       | 1       | Proper/undersized data frames transferred to promiscuous channel.                                                                                  |
| 0             | 1       | 0       | 1       | 0       | Proper data and control frames transferred to promiscuous channel.                                                                                 |
| 0             | 1       | 0       | 1       | 1       | Proper/undersized data and control frames transferred to promiscuous channel.                                                                      |
| 0             | 1       | 1       | 0       | 0       | Proper/oversize/jabber/code/align/CRC data frames transferred to promiscuous channel. No control or undersized/fragment frames are transferred.    |
| 0             | 1       | 1       | 0       | 1       | Proper/undersized/fragment/oversize/jabber/code/align/CRC data frames transferred to promiscuous channel. No control frames are transferred.       |
| 0             | 1       | 1       | 1       | 0       | Proper/oversize/jabber/code/align/CRC data and control frames transferred to promiscuous channel. No undersized frames are transferred.            |
| 0             | 1       | 1       | 1       | 1       | All nonaddress matching frames with and without errors transferred to promiscuous channel.                                                         |
| 1             | X       | 0       | 0       | 0       | Proper data frames transferred to address match channel.                                                                                           |
| 1             | X       | 0       | 0       | 1       | Proper/undersized data frames transferred to address match channel.                                                                                |
| 1             | X       | 0       | 1       | 0       | Proper data and control frames transferred to address match channel.                                                                               |
| 1             | X       | 0       | 1       | 1       | Proper/undersized data and control frames transferred to address match channel.                                                                    |
| 1             | X       | 1       | 0       | 0       | Proper/oversize/jabber/code/align/CRC data frames transferred to address match channel. No control or undersized frames are transferred.           |
| 1             | X       | 1       | 0       | 1       | Proper/oversize/jabber/fragment/undersized/code/align/CRC data frames transferred to address match channel. No control frames are transferred.     |
| 1             | X       | 1       | 1       | 0       | Proper/oversize/jabber/code/align/CRC data and control frames transferred to address match channel. No undersized/fragment frames are transferred. |
| 1             | X       | 1       | 1       | 1       | All address matching frames with and without errors transferred to the address match channel                                                       |

### 32.2.11.9 Receive Overrun

The types of receive overrun are:

- FIFO start of frame overrun (FIFO\_SOF)
- FIFO middle of frame overrun (FIFO\_MOF)
- DMA start of frame overrun (DMA\_SOF)
- DMA middle of frame overrun (DMA\_MOF)

The statistics counters used to track these types of receive overrun are:

- Receive start of frame overruns register (RXSOFOVERRUNS)
- Receive middle of frame overruns register (RXMOFOVERRUNS)
- Receive DMA overruns register (RXDMAOVERRUNS)

Start of frame overruns happen when there are no resources available when frame reception begins. Start of frame overruns increment the appropriate overrun statistic(s) and the frame is filtered.

Middle of frame overruns happen when there are some resources to start the frame reception, but the resources run out during frame reception. In normal operation, a frame that overruns after starting the frame reception is filtered and the appropriate statistic(s) are incremented; however, the RXCEFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) affects overrun frame treatment. [Table 32-8](#) shows how the overrun condition is handled for the middle of frame overrun.

**Table 32-8. Middle of Frame Overrun Treatment**

| Address Match | RXCAFEN | RXCEFEN | Middle of Frame Overrun Treatment                                                                                                                                                                                                                                                                                                                         |
|---------------|---------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0             | 0       | X       | Overrun frame filtered.                                                                                                                                                                                                                                                                                                                                   |
| 0             | 1       | 0       | Overrun frame filtered.                                                                                                                                                                                                                                                                                                                                   |
| 0             | 1       | 1       | As much frame data as possible is transferred to the promiscuous channel until overrun. The appropriate overrun statistic(s) is incremented and the OVERRUN and NOMATCH flags are set in the SOP buffer descriptor. Note that the RXMAXLEN number of bytes cannot be reached for an overrun to occur (it would be truncated and be a jabber or oversize). |
| 1             | X       | 0       | Overrun frame filtered with the appropriate overrun statistic(s) incremented.                                                                                                                                                                                                                                                                             |
| 1             | X       | 1       | As much frame data as possible is transferred to the address match channel until overrun. The appropriate overrun statistic(s) is incremented and the OVERRUN flag is set in the SOP buffer descriptor. Note that the RXMAXLEN number of bytes cannot be reached for an overrun to occur (it would be truncated).                                         |

### 32.2.12 Packet Transmit Operation

The transmit DMA is an eight channel interface. Priority between the eight queues may be either fixed or round-robin as selected by the TXPTYPE bit in the MAC control register (MACCONTROL). If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round-robin priority proceeds from channel 0 to channel 7.

#### 32.2.12.1 Transmit DMA Host Configuration

To configure the transmit DMA for operation the host must perform:

- Write the MAC source address low bytes register (MACSRCADDRLO) and the MAC source address high bytes register (MACSRCADDRHI) (used for pause frames on transmit).
- Initialize the transmit channel *n* DMA head descriptor pointer registers (TXnHDP) to 0.
- Enable the desired transmit interrupts using the transmit interrupt mask set register (TXINTMASKSET) and the transmit interrupt mask clear register (TXINTMASKCLEAR).
- Set the appropriate configuration bits in the MAC control register (MACCONTROL).
- Setup the transmit channel(s) buffer descriptors in host memory.
- Enable the transmit DMA controller by setting the TXEN bit in the transmit control register (TXCONTROL).
- Write the appropriate TXnHDP with the pointer to the first descriptor to start transmit operations.

#### 32.2.12.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the transmit teardown register (TXTEARDOWN). When a teardown command is issued to an enabled transmit channel, the following occurs:

- Any frame currently in transmission completes normally.
- The TDOWNCMPLT flag is set in the next SOP buffer descriptor in the chain, if there is one.
- The channel head descriptor pointer is cleared to 0.
- A transmit interrupt is issued to inform the host of the channel teardown.
- The corresponding transmit channel *n* completion pointer register (TXnCP) contains the value FFFF FFFCh.
- The host should acknowledge a teardown interrupt with an FFFF FFFCh acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete (TDOWNCMPLT) buffer descriptor bit. The EMAC does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with an FFFF FFFCh acknowledge value to TXnCP (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location (TXnCP) to determine if the interrupt was due to a commanded teardown. The read value is FFFF FFFCh, if the interrupt was due to a teardown command.

### 32.2.13 Receive and Transmit Latency

The transmit and receive FIFOs each contain three 64-byte cells. The EMAC begins transmission of a packet on the wire after TXCELLTHRESH (configurable through the FIFO control register) cells, or a complete packet, are available in the FIFO.

Transmit underrun cannot occur for packet sizes of TXCELLTHRESH times 64 bytes (or less). For larger packet sizes, transmit underrun occurs if the memory latency is greater than the time required to transmit a 64-byte cell on the wire; this is 5.12  $\mu$ s in 100 Mbps mode and 51.2  $\mu$ s in 10 Mbps mode. The memory latency time includes all buffer descriptor reads for the entire cell data.

Receive overrun is prevented if the receive memory cell latency is less than the time required to transmit a 64-byte cell on the wire: 5.12  $\mu$ s in 100 Mbps mode, or 51.2  $\mu$ s in 10 Mbps mode. The latency time includes any required buffer descriptor reads for the cell data.

Latency to system's internal and external RAM can be controlled through the use of the transfer node priority allocation register available at the device level. Latency to descriptor RAM is low because RAM is local to the EMAC, as it is part of the EMAC control module.

### 32.2.14 Transfer Node Priority

The device contains a chip-level master priority register that is used to set the priority of the transfer node used in issuing memory transfer requests to system memory.

Although the EMAC has internal FIFOs to help alleviate memory transfer arbitration problems, the average transfer rate of data read and written by the EMAC to internal or external processor memory must be at least that of the Ethernet wire rate. In addition, the internal FIFO system can not withstand a single memory latency event greater than the time it takes to fill or empty a TXCELLTHRESH number of internal 64 byte FIFO cells.

For 100 Mbps operation, these restrictions translate into the following rules:

- The short-term average, each 64-byte memory read/write request from the EMAC must be serviced in no more than 5.12  $\mu$ s.
- Any single latency event in request servicing can be no longer than  $(5.12 \times \text{TXCELLTHRESH}) \mu$ s.

## 32.2.15 Reset Considerations

### 32.2.15.1 Software Reset Considerations

The peripheral clock is controlled by the Global Clock Module (GCM), while the reset to the EMAC, MDIO and EMAC control module is controlled by the system module. See the "Architecture" chapter of the Technical Reference Manual for more on how to enable or disable the peripheral clock to the EMAC, MDIO and EMAC control module. For more on how the EMAC, MDIO, and EMAC control module are disabled or placed in reset at runtime, see [Section 32.2.18](#).

Within the peripheral itself, the EMAC component of the Ethernet MAC peripheral can be placed in a reset state by writing to the soft reset register (SOFTRESET). Writing a 1 to the SOFTRESET bit causes the EMAC logic to be reset and the register values to be set to their default values. Software reset occurs when the receive and transmit DMA controllers are in an idle state to avoid locking up the configuration bus; it is the responsibility of the software to verify that there are no pending frames to be transferred. After writing a 1 to the SOFTRESET bit, it may be polled to determine if the reset has occurred. If a 1 is read, the reset has not yet occurred; if a 0 is read, then a reset has occurred.

After a software reset operation, all the EMAC registers need to be reinitialized for proper data transmission, including the FULLDUPLEX bit setting in the MAC control register (MACCONTROL).

Unlike the EMAC module, the MDIO and EMAC control modules cannot be placed in reset from a register inside their memory map.

### 32.2.15.2 Hardware Reset Considerations

When a hardware reset occurs, the EMAC peripheral has its register values reset and all the components return to their default state. After the hardware reset, the EMAC needs to be initialized before being able to resume its data transmission, as described in [Section 32.2.16](#).

A hardware reset is the only means of recovering from the error interrupts (HOSTPEND), which are triggered by errors in packet buffer descriptors. Before doing a hardware reset, you should inspect the error codes in the MAC status register (MACSTATUS) that gives information about the type of software error that needs to be corrected. For detailed information on error interrupts, see [Section 32.2.17.1.4](#).

## 32.2.16 Initialization

### 32.2.16.1 Enabling the EMAC/MDIO Peripheral

When the device is powered on, the EMAC peripheral becomes enabled as soon as the system reset is released, and the EMAC peripheral registers are set to their default values. The application software can configure the EMAC peripheral registers as required.

### 32.2.16.2 EMAC Control Module Initialization

The EMAC control module is used for global interrupt enables and to pace interrupts using 1ms time windows. There is also an 8K block of CPPI RAM local to the EMAC that is used to hold packet buffer descriptors.

Note that although the EMAC control module and the EMAC module have slightly different functions, in practice, the type of maintenance performed on the EMAC control module is more commonly conducted from the EMAC module software (as opposed to the MDIO module).

The initialization of the EMAC control module consists of two parts:

1. Configuration of the interrupt to the CPU.
2. Initialization of the EMAC control module:
  - Setting the interrupt pace counts using the EMAC control module registers INTCONTROL, CORXIMAX, and COTXIMAX
  - Initializing the EMAC and MDIO modules
  - Enabling interrupts in the EMAC control module using the EMAC control module interrupt control registers CORXTHRESHEN, CORXEN, COTXEN, and COMISCEN.

The process of mapping the EMAC interrupts to the CPU is done through the Vectored Interrupt Manager (VIM). Once the interrupt is mapped to a CPU interrupt, general masking and unmasking of interrupts (to control reentrancy) should be done at the chip level by manipulating the interrupt core enable mask registers.

### 32.2.16.3 MDIO Module Initialization

The MDIO module is used to initially configure and monitor one or more external PHY devices. Other than initializing the software state machine (details on this state machine can be found in the IEEE 802.3 standard), all that needs to be done for the MDIO module is to enable the MDIO engine and to configure the clock divider. To set the clock divider, supply an MDIO clock of 1 MHz. For example, if the peripheral clock is 50 MHz, the divider can be set to 50.

Both the state machine enable and the MDIO clock divider are controlled through the MDIO control register (CONTROL). If none of the potentially connected PHYs require the access preamble, the PREAMBLE bit in CONTROL can also be set to speed up PHY register access.

If the MDIO module is to operate on an interrupt basis, the interrupts can be enabled at this time using the MDIO user command complete interrupt mask set register (USERINTMASKSET) for register access and the MDIO user PHY select register (USERPHYSEL<sub>n</sub>) if a target PHY is already known.

Once the MDIO state machine has been initialized and enabled, it starts polling all 32 PHY addresses on the MDIO bus, looking for an active PHY. Since it can take up to 50  $\mu$ s to read one register, it can be some time before the MDIO module provides an accurate representation of whether a PHY is available. Also, a PHY can take up to 3 seconds to negotiate a link. Thus, it is advisable to run the MDIO software off a time-based event rather than polling.

For more information on PHY control registers, see your PHY device documentation.

### 32.2.16.4 EMAC Module Initialization

The EMAC module is used to send and receive data packets over the network. This is done by maintaining up to eight transmit and receive descriptor queues. The EMAC module configuration must also be kept up-to-date based on PHY negotiation results returned from the MDIO module. Most of the work in developing an application or device driver for Ethernet is programming this module.

The following is the initialization procedure a device driver would follow to get the EMAC to the state where it is ready to receive and send Ethernet packets. Some of these steps are not necessary when performed immediately after device reset.

1. If enabled, clear the device interrupt enable bits in the EMAC control module interrupt control registers C0RXTHRESHEN, C0RXEN, C0TXEN, and C0MISCEN.
2. Clear the MAC control register (MACCONTROL), receive control register (RXCONTROL), and transmit control register (TXCONTROL) (not necessary immediately after reset).
3. Initialize all 16 header descriptor pointer registers (RXnHDP and TXnHDP) to 0.
4. Clear all 36 statistics registers by writing 0 (not necessary immediately after reset).
5. Setup the local Ethernet MAC address by programming the MAC index register (MACINDEX), MAC address high bytes register (MACADDRHI), and MAC address low bytes register (MACADDRLO). Be sure to program all eight MAC address registers - whether the receive channel is to be enabled or not. Duplicate the same MAC address across all unused channels. When using more than one receive channel, start with channel 0 and progress upwards.
6. If buffer flow control is to be enabled, initialize the receive channel *n* free buffer count registers (RXnFREEBUFFER), receive channel *n* flow control threshold register (RXnFLOWTHRESH), and receive filter low priority frame threshold register (RXFILTERLOWTHRESH).
7. Most device drivers open with no multicast addresses, so clear the MAC address hash registers (MACHASH1 and MACHASH2) to 0.
8. Write the receive buffer offset register (RXBUFFEROFFSET) value (typically zero).
9. Initially clear all unicast channels by writing FFh to the receive unicast clear register (RXUNICASTCLEAR). If unicast is desired, it can be enabled now by writing the receive unicast set register (RXUNICASTSET). Some drivers will default to unicast on device open while others will not.
10. Setup the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) with an initial configuration. The configuration is based on the current receive filter settings of the device driver. Some drivers may enable things like broadcast and multicast packets immediately, while others may not.
11. Set the appropriate configuration bits in MACCONTROL (do not set the GMIIEN bit yet).
12. Clear all unused channel interrupt bits by writing the receive interrupt mask clear register (RXINTMASKCLEAR) and the transmit interrupt mask clear register (TXINTMASKCLEAR).
13. Enable the receive and transmit channel interrupt bits in the receive interrupt mask set register (RXINTMASKSET) and the transmit interrupt mask set register (TXINTMASKSET) for the channels to be used, and enable the HOSTMASK and STATMASK bits using the MAC interrupt mask set register (MACINTMASKSET).
14. Initialize the receive and transmit descriptor list queues.
15. Prepare receive by writing a pointer to the head of the receive buffer descriptor list to RXnHDP.
16. Enable the receive and transmit DMA controllers by setting the RXEN bit in RXCONTROL and the TXEN bit in TXCONTROL. Then set the GMIIEN bit in MACCONTROL.
17. Enable the device interrupt in EMAC control module registers C0RXTHRESHEN, C0RXEN, C0TXEN, and C0MISCEN.

## 32.2.17 Interrupt Support

### 32.2.17.1 EMAC Module Interrupt Events and Requests

The EMAC module generates 26 interrupt events:

- TXPEND $n$ : Transmit packet completion interrupt for transmit channels 0 through 7
- RXPEND $n$ : Receive packet completion interrupt for receive channels 0 through 7
- RXTRESHPEND $n$ : Receive packet completion interrupt for receive channels 0 through 7 when flow control is enabled and the number of free buffers is below the threshold
- STATPEND: Statistics interrupt
- HOSTPEND: Host error interrupt

#### 32.2.17.1.1 Transmit Packet Completion Interrupts

The transmit DMA engine has eight channels, with each channel having a corresponding interrupt (TXPEND $n$ ). The transmit interrupts are level interrupts that remain asserted until cleared by the CPU.

Each of the eight transmit channel interrupts may be individually enabled by setting the appropriate bit in the transmit interrupt mask set register (TXINTMASKSET) to 1. Each of the eight transmit channel interrupts may be individually disabled by clearing the appropriate bit by writing a 1 to the transmit interrupt mask clear register (TXINTMASKCLEAR). The raw and masked transmit interrupt status may be read by reading the transmit interrupt status (unmasked) register (TXINTSTATRAW) and the transmit interrupt status (masked) register (TXINTSTATMASKED), respectively.

When the EMAC completes the transmission of a packet, the EMAC issues an interrupt to the CPU (via the EMAC control module) when it writes the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges an interrupt by writing the address of the last buffer descriptor processed to the queue's associated transmit completion pointer in the transmit DMA state RAM.

The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the EMAC port (address of last buffer descriptor used by the EMAC). If the two values are not equal (which means that the EMAC has transmitted more packets than the CPU has processed interrupts for), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the EMAC has transferred), the pending interrupt is cleared. The value that the EMAC is expecting is found by reading the transmit channel  $n$  completion pointer register (TX $n$ CP).

The EMAC write to the completion pointer actually stores the value in the state RAM. The CPU written value does not actually change the register value. The host written value is compared to the register content (which was written by the EMAC) and if the two values are equal then the interrupt is removed; otherwise, the interrupt remains asserted. The host may process multiple packets prior to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

The application software must acknowledge the EMAC control module after processing packets by writing the appropriate C0RX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See [Section 32.5.12](#) for the acknowledge key values.

#### 32.2.17.1.2 Receive Packet Completion Interrupts

The receive DMA engine has eight channels, which each channel having a corresponding interrupt (RXPEND $n$ ). The receive interrupts are level interrupts that remain asserted until cleared by the CPU.

Each of the eight receive channel interrupts may be individually enabled by setting the appropriate bit in the receive interrupt mask set register (RXINTMASKSET) to 1. Each of the eight receive channel interrupts may be individually disabled by clearing the appropriate bit by writing a 1 in the receive interrupt mask clear register (RXINTMASKCLEAR). The raw and masked receive interrupt status may be read by reading the receive interrupt status (unmasked) register (RXINTSTATRAW) and the receive interrupt status (masked) register (RXINTSTATMASKED), respectively.

When the EMAC completes a packet reception, the EMAC issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer in the receive DMA state RAM.

The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the EMAC (address of last buffer descriptor used by the EMAC). If the two values are not equal (which means that the EMAC has received more packets than the CPU has processed interrupts for), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the EMAC has received), the pending interrupt is de-asserted. The value that the EMAC is expecting is found by reading the receive channel *n* completion pointer register (RXnCP).

The EMAC write to the completion pointer actually stores the value in the state RAM. The CPU written value does not actually change the register value. The host written value is compared to the register content (which was written by the EMAC) and if the two values are equal then the interrupt is removed; otherwise, the interrupt remains asserted. The host may process multiple packets prior to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

The application software must acknowledge the EMAC control module after processing packets by writing the appropriate COTX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See [Section 32.5.12](#) for the acknowledge key values.

#### 32.2.17.1.3 Statistics Interrupt

The statistics level interrupt (STATPEND) is issued when any statistics value is greater than or equal to 8000 0000h, if enabled by setting the STATMASK bit in the MAC interrupt mask set register (MACINTMASKSET) to 1. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. As long as the most-significant bit of any statistics value is set, the interrupt remains asserted.

The application software must acknowledge the EMAC control module after receiving statistics interrupts by writing the appropriate COMISC key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See [Section 32.5.12](#) for the acknowledge key values.

#### 32.2.17.1.4 Host Error Interrupt

The host error interrupt (HOSTPEND) is issued, if enabled, under error conditions dealing with the handling of buffer descriptors, detected during transmit or receive DMA transactions. The failure of the software application to supply properly formatted buffer descriptors results in this error. The error bit can only be cleared by resetting the EMAC module in hardware.

The host error interrupt is enabled by setting the HOSTMASK bit in the MAC interrupt mask set register (MACINTMASKSET) to 1. The host error interrupt is disabled by clearing the appropriate bit by writing a 1 in the MAC interrupt mask clear register (MACINTMASKCLEAR). The raw and masked host error interrupt status may be read by reading the MAC interrupt status (unmasked) register (MACINTSTATRAW) and the MAC interrupt status (masked) register (MACINTSTATMASKED), respectively.

The transmit host error conditions are:

- SOP error
- Ownership bit not set in SOP buffer
- Zero next buffer descriptor pointer with EOP
- Zero buffer pointer
- Zero buffer length
- Packet length error

The receive host error conditions are:

- Ownership bit not set in input buffer
- Zero buffer pointer

The application software must acknowledge the EMAC control module after receiving host error interrupts by writing the appropriate COMISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 32.5.12](#) for the acknowledge key values.

### 32.2.17.1.5 Receive Threshold Interrupts

Each of the eight receive channels have a corresponding receive threshold interrupt (RXnTHRESHPEND). The receive threshold interrupts are level interrupts that remain asserted until the triggering condition is cleared by the host. Each of the eight threshold interrupts may be individually enabled by setting to 1 the appropriate bit in the RXINTMASKSET register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit by writing a 1 in the receive interrupt mask clear register (RXINTMASKCLEAR). The raw and masked interrupt receive interrupt status may be read by reading the receive interrupt status (unmasked) register (RXINTSTATRAW) and the receive interrupt status (masked) register (RXINTSTATMASKED), respectively.

An RXnTHRESHPEND interrupt bit is asserted when enabled and when the channel's associated free buffer count (RXnFREEBUFFER) is less than or equal to the channel's associated flow control threshold register (RXnFLOWTHRESH). The receive threshold interrupts use the same free buffer count and threshold logic as does flow control, but the interrupts are independently enabled from flow control. The threshold interrupts are intended to give the host an indication that resources are running low for a particular channel(s).

The applications software must acknowledge the EMAC control module after receiving threshold interrupts by writing the appropriate CORXTHRESH key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 32.5.12](#) for the acknowledge key values.

### 32.2.17.2 MDIO Module Interrupt Events and Requests

The MDIO module generates two interrupt events:

- LINKINT0: Serial interface link change interrupt. Indicates a change in the state of the PHY link selected by the USERPHYSEL0 register
- USERINT0: Serial interface user command event complete interrupt selected by the USERACCESS0 register

#### 32.2.17.2.1 Link Change Interrupt

The MDIO module asserts a link change interrupt (LINKINT0) if there is a change in the link state of the PHY corresponding to the address in the PHYADRMON bit in the MDIO register USERPHYSEL0, and if the LINKINTENB bit is also set in USERPHYSEL0. This interrupt event is also captured in the LINKINTRAW bit in the MDIO link status change interrupt register (LINKINTRAW). LINKINTRAW bits 0 and 1 correspond to USERPHYSEL0 and USERPHYSEL1, respectively.

When the interrupt is enabled and generated, the corresponding LINKINTMASKED bit is also set in the MDIO link status change interrupt register (LINKINTMASKED). The interrupt is cleared by writing back the same bit to LINKINTMASKED (write to clear).

The application software must acknowledge the EMAC control module after receiving MDIO interrupts by writing the appropriate COMISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 32.5.12](#) for the acknowledge key values.

### 32.2.17.2.2 User Access Completion Interrupt

When the GO bit in one of the MDIO register USERACCESS0 transitions from 1 to 0 (indicating completion of a user access) and the corresponding USERINTMASKSET bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) corresponding to USERACCESS0 is set, a user access completion interrupt (USERINT) is asserted. This interrupt event is also captured in the USERINTRAW bit in the MDIO user command complete interrupt register (USERINTRAW).

USERINTRAW bits 0 and bit 1 correspond to USERACCESS0 and USERACCESS1, respectively.

When the interrupt is enabled and generated, the corresponding USERINTMASKED bit is also set in the MDIO user command complete interrupt register (USERINTMASKED). The interrupt is cleared by writing back the same bit to USERINTMASKED (write to clear).

The application software must acknowledge the EMAC control module after receiving MDIO interrupts by writing the appropriate COMISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 32.5.12](#) for the acknowledge key values.

### 32.2.17.3 Proper Interrupt Processing

All the interrupts signaled from the EMAC and MDIO modules are level driven, so if they remain active, their level remains constant; the CPU core may require edge- or pulse-triggered interrupts. In order to properly convert the level-driven interrupt signal to an edge- or pulse-triggered signal, the application software must make use of the interrupt control logic contained in the EMAC control module.

[Section 32.2.7.3](#) discusses the interrupt control contained in the EMAC control module. For safe interrupt processing, upon entry to the ISR, the software application should disable interrupts using the EMAC control module registers CORXTHRESHEN, CORXEN, COTXEN, COMISCEN, and then reenables them upon leaving the ISR. If any interrupt signals are active at that time, this creates another rising edge on the interrupt signal going to the CPU interrupt controller, thus triggering another interrupt. The EMAC control module also uses the EMAC control module registers INTCONTROL, COTXIMAX, and CORXIMAX to implement interrupt pacing. The application software must acknowledge the EMAC control module by writing the appropriate key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 32.5.12](#) for the acknowledge key values.

### 32.2.17.4 Interrupt Multiplexing

The EMAC control module combines different interrupt signals from both the EMAC and MDIO modules into four interrupt signals (CORXTHRESHPULSE, CORXPULSE, COTXPULSE, COMISCPULSE) that are routed to the Vectored Interrupt Manager (VIM). The VIM is capable of relaying all four interrupt signals to the CPU.

When an interrupt is generated, the reason for the interrupt can be read from the MAC input vector register (MACINVECTOR) located in the EMAC memory map. MACINVECTOR combines the status of the following 28 interrupt signals: TXPEND<sub>n</sub>, RXPEND<sub>n</sub>, RXTHRESHPEND<sub>n</sub>, STATPEND, HOSTPEND, LINKINT0, and USERINT0.

For more details on the interrupt mapping, see your device-specific datasheet and VIM chapter of the Technical Reference Manual.

### 32.2.18 Power Management

Each of the three main components of the EMAC peripheral can be placed in a reduced-power mode to conserve power during periods of low activity. The peripheral clock to the EMAC peripheral is controlled by the processor Global Clock Module (GCM). The GCM allows the application to enable or disable the peripheral clock to the EMAC peripheral.

The power conservation modes available for each of the three components of the EMAC/MDIO peripheral are:

- *Idle/Disabled state.* This mode stops the clocks going to the peripheral, and prevents all the register accesses. After reenabling the peripheral from this idle state, all the registers values prior to setting into the disabled state are restored, and data transmission can proceed. No reinitialization is required.
- *System reset.* The EMAC peripheral is reset by the system reset signal output from the System module. Refer to the "Architecture" chapter of the Technical Reference Manual to identify the causes of a system reset. Upon a system reset, the registers are reset to their default value. When powering-up after a system reset, all the EMAC submodules need to be reinitialized before any data transmission can happen.

For more information on the use of the GCM, see your device-specific Technical Reference Manual.

### 32.2.19 Emulation Considerations

EMAC emulation control is implemented for compatibility with other peripherals. The SOFT and FREE bits in the emulation control register (EMCONTROL) allow EMAC operation to be suspended.

When the emulation suspend state is entered, the EMAC stops processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission is completed normally without suspension. For transmission, any complete or partial frame in the transmit cell FIFO is transmitted. For receive, frames that are detected by the EMAC after the suspend state is entered are ignored. No statistics are kept for ignored frames.

Table 32-9 shows how the SOFT and FREE bits affect the operation of the emulation suspend.

---

**NOTE:** Emulation suspend has not been tested.

---

**Table 32-9. Emulation Control**

| SOFT | FREE | Description       |
|------|------|-------------------|
| 0    | 0    | Normal operation  |
| 1    | 0    | Emulation suspend |
| X    | 1    | Normal operation  |

## 32.3 EMAC Control Module Registers

Table 32-10 lists the memory-mapped registers for the EMAC control module. The base address for these registers is 0xFCF78800.

**Table 32-10. EMAC Control Module Registers**

| 0    | RESET    |       | Software reset bit for the EMAC Control Module. Clears the interrupt status, control registers, and CPPI Ram on the clock cycle following a write of 1. |
|      |          | 0     | No software reset.                                                                                                                                      |
|      |          | 1     | Perform a software reset.                                                                                                                               |

### 32.3.3 EMAC Control Module Interrupt Control Register (INTCONTROL)

The EMAC control module interrupt control register (INTCONTROL) is shown in [Figure 32-14](#) and described in [Table 32-13](#). The settings in the INTCONTROL register are used in conjunction with the CnRXIMAX and CnTXIMAX registers.

**Figure 32-14. EMAC Control Module Interrupt Control Register (INTCONTROL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 32-13. EMAC Control Module Interrupt Control Register (INTCONTROL)**

### 32.3.12 EMAC Control Module Receive Interrupts Per Millisecond Registers (C0RXIMAX)

The EMAC control module receive interrupts per millisecond register (C0RXIMAX) is shown in [Figure 32-23](#) and described in [Table 32-22](#)

**Figure 32-23. EMAC Control Module Receive Interrupts Per Millisecond Register (C0RXIMAX)**

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

**Table 32-22. EMAC Control Module Receive Interrupts Per Millisecond Register (C0RXIMAX)**

| Bit  | Field    | Value | Description                                                                                                              |
|------|----------|-------|--------------------------------------------------------------------------------------------------------------------------|
| 31-6 | Reserved | 0     | Reserved                                                                                                                 |
| 5-0  | RXIMAX   | 2-3Fh | RXIMAX is the desired number of C0RXPULSE interrupts generated per millisecond when C0RXPACEEN is enabled in INTCONTROL. |

The pacing mechanism can be described by the following pseudo-code:

```

while(1) {
    interrupt_count = 0;

    /* Count interrupts over a 1ms window */
    for(i = 0; i < INTCONTROL[INTPRESCALE]*250; i++) {
        interrupt_count += NEW_INTERRUPT_EVENTS();

        if(i < INTCONTROL[INTPRESCALE]*pace_counter)
            BLOCK_EMAC_INTERRUPTS();
        else
            ALLOW_EMAC_INTERRUPTS();
    }

    ALLOW_EMAC_INTERRUPTS();

    if(interrupt_count > 2*RXIMAX)
        pace_counter = 255;
    else if(interrupt_count > 1.5*RXIMAX)
        pace_counter = previous_pace_counter*2 + 1;
    else if(interrupt_count > 1.0*RXIMAX)
        pace_counter = previous_pace_counter + 1;
    else if(interrupt_count > 0.5*RXIMAX)
        pace_counter = previous_pace_counter - 1;
    else if(interrupt_count != 0)
        pace_counter = previous_pace_counter/2;
    else
        pace_counter = 0;

    previous_pace_counter = pace_counter;
}

```

### 32.3.13 EMAC Control Module Transmit Interrupts Per Millisecond Registers (C0TXIMAX)

The EMAC control module transmit interrupts per millisecond register (C0TXIMAX) is shown in [Figure 32-24](#) and described in [Table 32-23](#)

**Figure 32-24. EMAC Control Module Transmit Interrupts Per Millisecond Register (C0TXIMAX)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 32-23. EMAC Control Module Transmit Interrupts Per Millisecond Register (C0TXIMAX)**

| Bit  | Field    | Value | Description                                                                                                              |
|------|----------|-------|--------------------------------------------------------------------------------------------------------------------------|
| 31-6 | Reserved | 0     | Reserved                                                                                                                 |
| 5-0  | TXIMAX   | 2-3Fh | TXIMAX is the desired number of C0TXPULSE interrupts generated per millisecond when C0TXPACEEN is enabled in INTCONTROL. |

The pacing mechanism can be described by the following pseudo-code:

```

while(1) {
    interrupt_count = 0;

    /* Count interrupts over a 1ms window */
    for(i = 0; i < INTCONTROL[INTPRESCALE]*250; i++) {
        interrupt_count += NEW_INTERRUPT_EVENTS();

        if(i < INTCONTROL[INTPRESCALE]*pace_counter)
            BLOCK_EMAC_INTERRUPTS();
        else
            ALLOW_EMAC_INTERRUPTS();
    }

    ALLOW_EMAC_INTERRUPTS();

    if(interrupt_count > 2*TXIMAX)
        pace_counter = 255;
    else if(interrupt_count > 1.5*TXIMAX)
        pace_counter = previous_pace_counter*2 + 1;
    else if(interrupt_count > 1.0*TXIMAX)
        pace_counter = previous_pace_counter + 1;
    else if(interrupt_count > 0.5*TXIMAX)
        pace_counter = previous_pace_counter - 1;
    else if(interrupt_count != 0)
        pace_counter = previous_pace_counter/2;
    else
        pace_counter = 0;

    previous_pace_counter = pace_counter;
}

```

## 32.4 MDIO Registers

Table 32-24 lists the memory-mapped registers for the MDIO module. The base address for these registers is FCF7 8900h.

**Table 32-24. Management Data Input/Output (MDIO) Registers**

| Offset | Acronym          | Register Description                                     | Section                         |

**Figure 32-27. PHY Acknowledge Status Register (ALIVE)**

LEGEND: R/W = Read/Write; W1C = Write 1 to clear (writing a 0 has no effect); -n = value after reset

**Table 32-27. PHY Acknowledge Status Register (ALIVE) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ALIVE |       | MDIO Alive bits. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY; the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. Writing a 1 to any bit will clear it, writing a 0 has no effect. |
|      |       | 0     | The PHY fails to acknowledge the access.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|      |       | 1     | The most recent access to the PHY with an address corresponding to the register bit number was acknowledged by the PHY.                                                                                                                                                                                                                                                                                                                                                                                                                             |

### 32.4.4 PHY Link Status Register (LINK)

The PHY link status register (LINK) is shown in [Figure 32-28](#) and described in [Table 32-28](#).

**Figure 32-28. PHY Link Status Register (LINK)**

LEGEND: R = Read only; -n = value after reset

**Table 32-28. PHY Link Status Register (LINK) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                            |
|------|-------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | LINK  |       | MDIO Link state bits. This register is updated after a read of the generic status register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect. |
|      |       | 0     | The PHY indicates it does not have a link or fails to acknowledge the read transaction                                                                                                                                                                                                                                                                                 |
|      |       | 1     | The PHY with the corresponding address has a link and the PHY acknowledges the read transaction.                                                                                                                                                                                                                                                                       |

### 32.4.5 MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW)

The MDIO link status change interrupt (unmasked) register (LINKINTRAW) is shown in [Figure 32-29](#) and described in [Table 32-29](#).

**Figure 32-29. MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW)**

**Table 32-32. MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED)**

| Bit  | Field       | Value | Description                                                                                                                                                                                                                                                               |
|------|-------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved    | 0     | Reserved                                                                                                                                                                                                                                                                  |
| 1    | USERACCESS1 |       | Masked value of MDIO User command complete interrupt. When asserted, The bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS1 register has completed. Writing a 1 will clear the interrupt, writing a 0 has no effect. |
|      |             | 0     | No MDIO user command complete event.                                                                                                                                                                                                                                      |
|      |             | 1     | The previously scheduled PHY read or write command using MDIO user access register USERACCESS1 has completed and the corresponding bit in USERINTMASKSET is set to 1.                                                                                                     |
| 0    | USERACCESS0 |       | Masked value of MDIO User command complete interrupt. When asserted, The bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS0 register has completed. Writing a 1 will clear the interrupt, writing a 0 has no effect. |
|      |             | 0     | No MDIO user command complete event.                                                                                                                                                                                                                                      |
|      |             | 1     | The previously scheduled PHY read or write command using MDIO user access register USERACCESS0 has completed and the corresponding bit in USERINTMASKSET is set to 1.                                                                                                     |

### 32.4.9 MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET)

The MDIO user command complete interrupt mask set register (USERINTMASKSET) is shown in [Figure 32-33](#) and described in [Table 32-33](#).

**Figure 32-33. MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET)**

LEGEND: R/W = Read/Write; R = Read only; W1S = Write 1 to set (writing a 0 has no effect); -n = value after reset

**Table 32-33. MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET)  
Field Descriptions**

| Bit  | Field       | Value | Description                                                                                                                                                                                                                                                                 |
|------|-------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved    | 0     | Reserved                                                                                                                                                                                                                                                                    |
| 1    | USERACCESS1 | 0     | MDIO user interrupt mask set for USERINTMASKED[1]. Setting a bit to 1 will enable MDIO user command complete interrupts for the USERACCESS1 register. MDIO user interrupt for USERACCESS1 is disabled if the corresponding bit is 0. Writing a 0 to this bit has no effect. |
|      |             | 0     | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is disabled.                                                                                                                                                                            |
|      |             | 1     | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is enabled.                                                                                                                                                                             |
| 0    | USERACCESS0 |       | MDIO user interrupt mask set for USERINTMASKED[0]. Setting a bit to 1 will enable MDIO user command complete interrupts for the USERACCESS0 register. MDIO user interrupt for USERACCESS0 is disabled if the corresponding bit is 0. Writing a 0 to this bit has no effect. |
|      |             | 0     | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is disabled.                                                                                                                                                                            |
|      |             | 1     | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is enabled.                                                                                                                                                                             |

### 32.4.10 MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR)

The MDIO user command complete interrupt mask clear register (USERINTMASKCLEAR) is shown in [Figure 32-34](#) and described in [Table 32-34](#).

**Figure 32-34. MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR)**

**Table 32-34. MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR) Field Descriptions**

| Bit  | Field       | Value | Description                                                                                                                                                                                              |
|------|-------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved    | 0     | Reserved                                                                                                                                                                                                 |
| 1    | USERACCESS1 | 0     | MDIO user command complete interrupt mask clear for USERINTMASKED[1]. Setting the bit to 1 will disable further user command complete interrupts for USERACCESS1. Writing a 0 to this bit has no effect. |
|      |             | 0     | MDIO user command complete interrupts for the MDIO user access register USERACCESS1 is enabled.                                                                                                          |
|      |             | 1     | MDIO user command complete interrupts for the MDIO user access register USERACCESS1 is disabled.                                                                                                         |
| 0    | USERACCESS0 | 0     | MDIO user command complete interrupt mask clear for USERINTMASKED[0]. Setting the bit to 1 will disable further user command complete interrupts for USERACCESS0. Writing a 0 to this bit has no effect. |
|      |             | 0     | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is enabled.                                                                                                          |
|      |             | 1     | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is disabled.                                                                                                         |

### 32.4.11 MDIO User Access Register 0 (USERACCESS0)

The MDIO user access register 0 (USERACCESS0) is shown in [Figure 32-35](#) and described in [Table 32-35](#).

**Figure 32-35. MDIO User Access Register 0 (USERACCESS0)**

LEGEND: R/W = Read/Write; R = Read only; W1S = Write 1 to set (writing a 0 has no effect); -n = value after reset

**Table 32-35. MDIO User Access Register 0 (USERACCESS0) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | GO       | 0-1     | Go bit. Writing a 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so; this is not an instantaneous process. Writing a 0 to this bit has no effect. This bit is writeable only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to USERACCESS0 are blocked when the GO bit is 1. |
| 30    | WRITE    | 0<br>1  | Write enable bit. Setting this bit to 1 causes the MDIO transaction to be a register write; otherwise, it is a register read.<br>The user command is a read operation.<br>The user command is a write operation.                                                                                                                                                                                                |
| 29    | ACK      | 0-1     | Acknowledge bit. This bit is set if the PHY acknowledged the read transaction.                                                                                                                                                                                                                                                                                                                                  |
| 28-26 | Reserved | 0       | Reserved                                                                                                                                                                                                                                                                                                                                                                                                        |
| 25-21 | REGADR   | 0-1Fh   | Register address bits. This field specifies the PHY register to be accessed for this transaction                                                                                                                                                                                                                                                                                                                |
| 20-16 | PHYADR   | 0-1Fh   | PHY address bits. This field specifies the PHY to be accessed for this transaction.                                                                                                                                                                                                                                                                                                                             |
| 15-0  | DATA     | 0-FFFFh | User data bits. These bits specify the data value read from or to be written to the specified PHY register.                                                                                                                                                                                                                                                                                                     |

### 32.4.12 MDIO User PHY Select Register 0 (USERPHYSEL0)

The MDIO user PHY select register 0 (USERPHYSEL0) is shown in [Figure 32-36](#) and described in [Table 32-36](#).

**Figure 32-36. MDIO User PHY Select Register 0 (USERPHYSEL0)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 32-36. MDIO User PHY Select Register 0 (USERPHYSEL0) Field Descriptions**

| Bit  | Field      | Value  | Description                                                                                                                                                                                                                                                                                                               |

| 7    | LINKSEL    | 0<br>1 | Link status determination select bit. Default value is 0, which implies that the link status is determined by the MDIO state machine. This is the only option supported on this device.<br>The link status is determined by the MDIO state machine.<br>Not supported.                                                     |
| 6    | LINKINTENB | 0<br>1 | Link change interrupt enable. Set to 1 to enable link change status interrupts for PHY address specified in PHYADRMON. Link change interrupts are disabled if this bit is cleared to 0.<br>Link change interrupts are disabled.<br>Link change status interrupts for PHY address specified in PHYADRMON bits are enabled. |
| 5    | Reserved   | 0      | Reserved                                                                                                                                                                                                                                                                                                                  |
| 4-0  | PHYADRMON  | 0-1Fh  | PHY address whose link status is to be monitored.                                                                                                                                                                                                                                                                         |

### 32.4.13 MDIO User Access Register 1 (USERACCESS1)

The MDIO user access register 1 (USERACCESS1) is shown in [Figure 32-37](#) and described in [Table 32-37](#).

**Figure 32-37. MDIO User Access Register 1 (USERACCESS1)**

LEGEND: R/W = Read/Write; R = Read only; W1S = Write 1 to set (writing a 0 has no effect); -n = value after reset

**Table 32-37. MDIO User Access Register 1 (USERACCESS1) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------|----------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | GO       | 0-1     | Go bit. Writing 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so; this is not an instantaneous process. Writing 0 to this bit has no effect. This bit is writeable only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to USERACCESS0 are blocked when the GO bit is 1. |
| 30    | WRITE    | 0<br>1  | Write enable bit. Setting this bit to 1 causes the MDIO transaction to be a register write; otherwise, it is a register read.<br>The user command is a read operation.<br>The user command is a write operation.                                                                                                                                                                                            |
| 29    | ACK      | 0-1     | Acknowledge bit. This bit is set if the PHY acknowledged the read transaction.                                                                                                                                                                                                                                                                                                                              |
| 28-26 | Reserved | 0       | Reserved                                                                                                                                                                                                                                                                                                                                                                                                    |
| 25-21 | REGADR   | 0-1Fh   | Register address bits. This field specifies the PHY register to be accessed for this transaction                                                                                                                                                                                                                                                                                                            |
| 20-16 | PHYADR   | 0-1Fh   | PHY address bits. This field specifies the PHY to be accessed for this transaction.                                                                                                                                                                                                                                                                                                                         |
| 15-0  | DATA     | 0-FFFFh | User data bits. These bits specify the data value read from or to be written to the specified PHY register.                                                                                                                                                                                                                                                                                                 |

### 32.4.14 MDIO User PHY Select Register 1 (USERPHYSEL1)

The MDIO user PHY select register 1 (USERPHYSEL1) is shown in [Figure 32-38](#) and described in [Table 32-38](#).

**Figure 32-38. MDIO User PHY Select Register 1 (USERPHYSEL1)**

### 32.5.1 Transmit Revision ID Register (TXREVID)

The transmit revision ID register (TXREVID) is shown in [Figure 32-39](#) and described in [Table 32-40](#).

**Figure 32-39. Transmit Revision ID Register (TXREVID)**

LEGEND: R = Read only; -n = value after reset

**Table 32-40. Transmit Revision ID Register (TXREVID) Field Descriptions**

| Bit  | Field | Value      | Description                                                 |
|------|-------|------------|-------------------------------------------------------------|
| 31-0 | TXREV | 4EC0 020Dh | Transmit module revision<br>Current transmit revision value |

### 32.5.2 Transmit Control Register (TXCONTROL)

The transmit control register (TXCONTROL) is shown in [Figure 32-40](#) and described in [Table 32-41](#).

**Figure 32-40. Transmit Control Register (TXCONTROL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 32-41. Transmit Control Register (TXCONTROL) Field Descriptions**

| Bit  | Field    | Value | Description                              |
|------|----------|-------|------------------------------------------|
| 31-1 | Reserved | 0     | Reserved                                 |
| 0    | TXEN     | 0     | Transmit enable<br>Transmit is disabled. |
|      |          | 1     | Transmit is enabled.                     |

### 32.5.3 Transmit Teardown Register (TXTEARDOWN)

The transmit teardown register (TXTEARDOWN) is shown in [Figure 32-41](#) and described in [Table 32-42](#).

**Figure 32-41. Transmit Teardown Register (TXTEARDOWN)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 32-42. Transmit Teardown Register (TXTEARDOWN) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                     |
|------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | Reserved                                                                                                                                                                        |
| 2-0  | TXTDNCH  | 0-7h  | Transmit teardown channel. The transmit channel teardown is commanded by writing the encoded value of the transmit channel to be torn down. The teardown register is read as 0. |
|      |          | 0     | Teardown transmit channel 0                                                                                                                                                     |
|      |          | 1h    | Teardown transmit channel 1                                                                                                                                                     |
|      |          | 2h    | Teardown transmit channel 2                                                                                                                                                     |

### 32.5.7 Transmit Interrupt Status (Unmasked) Register (TXINTSTATRAW)

The transmit interrupt status (unmasked) register (TXINTSTATRAW) is shown in [Figure 32-45](#) and described in [Table 32-46](#).

**Figure 32-45. Transmit Interrupt Status (Unmasked) Register (TXINTSTATRAW)**

LEGEND: R = Read only; -n = value after reset

**Table 32-46. Transmit Interrupt Status (Unmasked) Register (TXINTSTATRAW) Field Descriptions**

| Bit  | Field    | Value | Description                              |
|------|----------|-------|------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                 |
| 7    | TX7PEND  | 0-1   | TX7PEND raw interrupt read (before mask) |
| 6    | TX6PEND  | 0-1   | TX6PEND raw interrupt read (before mask) |
| 5    | TX5PEND  | 0-1   | TX5PEND raw interrupt read (before mask) |
| 4    | TX4PEND  | 0-1   | TX4PEND raw interrupt read (before mask) |
| 3    | TX3PEND  | 0-1   | TX3PEND raw interrupt read (before mask) |
| 2    | TX2PEND  | 0-1   | TX2PEND raw interrupt read (before mask) |
| 1    | TX1PEND  | 0-1   | TX1PEND raw interrupt read (before mask) |
| 0    | TX0PEND  | 0-1   | TX0PEND raw interrupt read (before mask) |

### 32.5.8 Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED)

The transmit interrupt status (masked) register (TXINTSTATMASKED) is shown in [Figure 32-46](#) and described in [Table 32-47](#).

**Figure 32-46. Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED)**

LEGEND: R = Read only; -n = value after reset

**Table 32-47. Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED) Field Descriptions**

| Bit  | Field    | Value | Description                   |
|------|----------|-------|-------------------------------|
| 31-8 | Reserved | 0     | Reserved                      |
| 7    | TX7PEND  | 0-1   | TX7PEND masked interrupt read |
| 6    | TX6PEND  | 0-1   | TX6PEND masked interrupt read |
| 5    | TX5PEND  | 0-1   | TX5PEND masked interrupt read |
| 4    | TX4PEND  | 0-1   | TX4PEND masked interrupt read |
| 3    | TX3PEND  | 0-1   | TX3PEND masked interrupt read |
| 2    | TX2PEND  | 0-1   | TX2PEND masked interrupt read |
| 1    | TX1PEND  | 0-1   | TX1PEND masked interrupt read |
| 0    | TX0PEND  | 0-1   | TX0PEND masked interrupt read |

### 32.5.9 Transmit Interrupt Mask Set Register (TXINTMASKSET)

The transmit interrupt mask set register (TXINTMASKSET) is shown in [Figure 32-47](#) and described in [Table 32-48](#).

**Figure 32-47. Transmit Interrupt Mask Set Register (TXINTMASKSET)**

LEGEND: R/W = Read/Write; R = Read only; W1S = Write 1 to set (writing a 0 has no effect); -n = value after reset

**Table 32-48. Transmit Interrupt Mask Set Register (TXINTMASKSET) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                         |
|------|----------|-------|-----------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                            |
| 7    | TX7MASK  | 0-1   | Transmit channel 7 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 6    | TX6MASK  | 0-1   | Transmit channel 6 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 5    | TX5MASK  | 0-1   | Transmit channel 5 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 4    | TX4MASK  | 0-1   | Transmit channel 4 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 3    | TX3MASK  | 0-1   | Transmit channel 3 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 2    | TX2MASK  | 0-1   | Transmit channel 2 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 1    | TX1MASK  | 0-1   | Transmit channel 1 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 0    | TX0MASK  | 0-1   | Transmit channel 0 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |

### 32.5.10 Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR)

The transmit interrupt mask clear register (TXINTMASKCLEAR) is shown in [Figure 32-48](#) and described in [Table 32-49](#).

**Figure 32-48. Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR)**

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -n = value after reset

**Table 32-49. Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                            |
|------|----------|-------|--------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                               |
| 7    | TX7MASK  | 0-1   | Transmit channel 7 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 6    | TX6MASK  | 0-1   | Transmit channel 6 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 5    | TX5MASK  | 0-1   | Transmit channel 5 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 4    | TX4MASK  | 0-1   | Transmit channel 4 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 3    | TX3MASK  | 0-1   | Transmit channel 3 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 2    | TX2MASK  | 0-1   | Transmit channel 2 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 1    | TX1MASK  | 0-1   | Transmit channel 1 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 0    | TX0MASK  | 0-1   | Transmit channel 0 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |

### 32.5.11 MAC Input Vector Register (MACINVECTOR)

The MAC input vector register (MACINVECTOR) is shown in [Figure 32-49](#) and described in [Table 32-50](#).

**Figure 32-49. MAC Input Vector Register (MACINVECTOR)**

|              |    |          |          |          |          |        |    |
|--------------|----|----------|----------|----------|----------|--------|----|
| 31           | 28 | 27       | 26       | 25       | 24       | 23     | 16 |
| Reserved     |    | STATPEND | HOSTPEND | LINKINT0 | USERINT0 | TXPEND |    |
| R-0          |    | R-0      | R-0      | R-0      | R-0      | R-0    |    |
| 15           |    |          |          |          | 8        | 7      | 0  |
| RXTHRESHPEND |    |          |          |          |          | RXPEND |    |
| R-0          |    |          |          |          |          | R-0    |    |

LEGEND: R = Read only; -n = value after reset

**Table 32-50. MAC Input Vector Register (MACINVECTOR) Field Descriptions**

| Bit   | Field        | Value | Description                                                                            |
|-------|--------------|-------|----------------------------------------------------------------------------------------|
| 31-28 | Reserved     | 0     | Reserved                                                                               |
| 27    | STATPEND     | 0-1   | EMAC module statistics interrupt (STATPEND) pending status bit                         |
| 26    | HOSTPEND     | 0-1   | EMAC module host error interrupt (HOSTPEND) pending status bit                         |
| 25    | LINKINT0     | 0-1   | MDIO module USERPHYSEL0 (LINKINT0) status bit                                          |
| 24    | USERINT0     | 0-1   | MDIO module USERACCESS0 (USERINT0) status bit                                          |
| 23-16 | TXPEND       | 0-FFh | Transmit channels 0-7 interrupt (TXnPEND) pending status. Bit 16 is TX0PEND.           |
| 15-8  | RXTHRESHPEND | 0-FFh | Receive channels 0-7 interrupt (RXnTHRESHPEND) pending status. Bit 8 is RX0THRESHPEND. |
| 7-0   | RXPEND       | 0-FFh | Receive channels 0-7 interrupt (RXnPEND) pending status bit. Bit 0 is RX0PEND.         |

### 32.5.12 MAC End Of Interrupt Vector Register (MACEOIVECTOR)

The MAC end of interrupt vector register (MACEOIVECTOR) is shown in [Figure 32-50](#) and described in [Table 32-51](#).

**Figure 32-50. MAC End Of Interrupt Vector Register (MACEOIVECTOR)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 32-51. MAC End Of Interrupt Vector Register (MACEOIVECTOR) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                     |
|------|----------|--------|---------------------------------------------------------------------------------|
| 31-5 | Reserved | 0      | Reserved                                                                        |

| 1     | RX1MASK       | 0-1   | Receive channel 1 mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect.           |
| 0     | RX0MASK       | 0-1   | Receive channel 0 mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect.           |

### 32.5.17 MAC Interrupt Status (Unmasked) Register (MACINTSTATRAW)

The MAC interrupt status (unmasked) register (MACINTSTATRAW) is shown in [Figure 32-55](#) and described in [Table 32-56](#).

**Figure 32-55. MAC Interrupt Status (Unmasked) Register (MACINTSTATRAW)**

LEGEND: R = Read only; -n = value after reset

**Table 32-56. MAC Interrupt Status (Unmasked) Register (MACINTSTATRAW) Field Descriptions**

| Bit  | Field    | Value | Description                                                                |
|------|----------|-------|----------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved                                                                   |
| 1    | HOSTPEND | 0-1   | Host pending interrupt (HOSTPEND); raw interrupt read (before mask).       |
| 0    | STATPEND | 0-1   | Statistics pending interrupt (STATPEND); raw interrupt read (before mask). |

### 32.5.18 MAC Interrupt Status (Masked) Register (MACINTSTATMASKED)

The MAC interrupt status (masked) register (MACINTSTATMASKED) is shown in [Figure 32-56](#) and described in [Table 32-57](#).

**Figure 32-56. MAC Interrupt Status (Masked) Register (MACINTSTATMASKED)**

LEGEND: R = Read only; -n = value after reset

**Table 32-57. MAC Interrupt Status (Masked) Register (MACINTSTATMASKED) Field Descriptions**

| Bit  | Field    | Value | Description                                                     |
|------|----------|-------|-----------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved                                                        |
| 1    | HOSTPEND | 0-1   | Host pending interrupt (HOSTPEND); masked interrupt read.       |
| 0    | STATPEND | 0-1   | Statistics pending interrupt (STATPEND); masked interrupt read. |

### 32.5.19 MAC Interrupt Mask Set Register (MACINTMASKSET)

The MAC interrupt mask set register (MACINTMASKSET) is shown in [Figure 32-57](#) and described in [Table 32-58](#).

**Figure 32-57. MAC Interrupt Mask Set Register (MACINTMASKSET)**

|     |          |  |  |  |  |  |  |  |  |         |   |          |          |         |  |    |

| 30    | RXPASSCRC | 0<br>1 | Pass receive CRC enable bit<br>Received CRC is discarded for all channels and is not included in the buffer descriptor packet length field.<br>Received CRC is transferred to memory for all channels and is included in the buffer descriptor packet length.                                                                                                                                                                                                                                                                               |
| 29    | RXQOSEN   | 0<br>1 | Receive quality of service enable bit<br>Receive QOS is disabled.<br>Receive QOS is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 28    | RXNOCHAIN | 0<br>1 | Receive no buffer chaining bit<br>Received frames can span multiple buffers.<br>The Receive DMA controller transfers each frame into a single buffer, regardless of the frame or buffer size. All remaining frame data after the first buffer is discarded. The buffer descriptor buffer length field will contain the entire frame byte count (up to 65535 bytes).                                                                                                                                                                         |
| 27-25 | Reserved  | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 24    | RXCMFEN   | 0<br>1 | Receive copy MAC control frames enable bit. Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in MACCONTROL, regardless of the value of RXCMFEN. Frames transferred to memory due to RXCMFEN will have the CONTROL bit set in their EOP buffer descriptor.<br>MAC control frames are filtered (but acted upon if enabled).<br>MAC control frames are transferred to memory. |
| 23    | RXCSFEN   | 0<br>1 | Receive copy short frames enable bit. Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to RXCSFEN will have the FRAGMENT or UNDERSIZE bit set in their EOP buffer descriptor. Fragments are short frames that contain CRC / align / code errors and undersized are short frames without errors.<br>Short frames are filtered.<br>Short frames are transferred to memory.                                                                                                          |

**Table 32-63. Receive Maximum Length Register (RXMAXLEN) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                  |
|-------|----------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved | 0       | Reserved                                                                                                                                                                                                                                                                                                     |
| 15-0  | RXMAXLEN | 0-FFFFh | Receive maximum frame length. These bits determine the maximum length of a received frame. The reset value is 5EEh (1518). Frames with byte counts greater than RXMAXLEN are long frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment error are jabber frames. |

### 32.5.25 Receive Buffer Offset Register (RXBUFFEROFFSET)

The receive buffer offset register (RXBUFFEROFFSET) is shown in [Figure 32-63](#) and described in [Table 32-64](#).

**Figure 32-63. Receive Buffer Offset Register (RXBUFFEROFFSET)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 32-64. Receive Buffer Offset Register (RXBUFFEROFFSET) Field Descriptions**

| Bit   | Field          | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------|----------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved       | 0       | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 15-0  | RXBUFFEROFFSET | 0-FFFFh | Receive buffer offset value. These bits are written by the EMAC into each frame SOP buffer descriptor Buffer Offset field. The frame data begins after the RXBUFFEROFFSET value of bytes. A value of 0 indicates that there are no unused bytes at the beginning of the data, and that valid data begins on the first byte of the buffer. A value of Fh (15) indicates that the first 15 bytes of the buffer are to be ignored by the EMAC and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels. |

### 32.5.26 Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)

The receive filter low priority frame threshold register (RXFILTERLOWTHRESH) is shown in [Figure 32-64](#) and described in [Table 32-65](#).

**Figure 32-64. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 32-65. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH) Field Descriptions**

| Bit  | Field          | Value | Description                                                                                                                                                                                |
|------|----------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved       | 0     | Reserved                                                                                                                                                                                   |
| 7-0  | RXFILTERTHRESH | 0-FFh | Receive filter low threshold. These bits contain the free buffer count threshold value for filtering low priority incoming frames. This field should remain 0, if no filtering is desired. |

### 32.5.27 Receive Channel Flow Control Threshold Registers (RX0FLOWTHRESH-RX7FLOWTHRESH)

The receive channel 0-7 flow control threshold register (RX $n$ FLOWTHRESH) is shown in [Figure 32-65](#) and described in [Table 32-66](#).

**Figure 32-65. Receive Channel  $n$  Flow Control Threshold Register (RX $n$ FLOWTHRESH)**

LEGEND: R/W = Read/Write; R = Read only; - $n$  = value after reset

**Table 32-66. Receive Channel  $n$  Flow Control Threshold Register (RX $n$ FLOWTHRESH) Field Descriptions**

| Bit  | Field             | Value | Description                                                                                                                                |
|------|-------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved          | 0     | Reserved                                                                                                                                   |
| 7-0  | RX $n$ FLOWTHRESH | 0-FFh | Receive flow threshold. These bits contain the threshold value for issuing flow control on incoming frames for channel $n$ (when enabled). |

### 32.5.28 Receive Channel Free Buffer Count Registers (RX0FREEBUFFER-RX7FREEBUFFER)

The receive channel 0-7 free buffer count register (RX $n$ FREEBUFFER) is shown in [Figure 32-66](#) and described in [Table 32-67](#).

**Figure 32-66. Receive Channel  $n$  Free Buffer Count Register (RX $n$ FREEBUFFER)**

LEGEND: R = Read only; WI = Write to increment; - $n$  = value after reset

**Table 32-67. Receive Channel  $n$  Free Buffer Count Register (RX $n$ FREEBUFFER) Field Descriptions**

| Bit   | Field          | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| 31-16 | Reserved       | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 15-0  | RX $n$ FREEBUF | 0-FFh | Receive free buffer count. These bits contain the count of free buffers available. The RXFILTERTHRESH value is compared with this field to determine if low priority frames should be filtered. The RX $n$ FLOWTHRESH value is compared with this field to determine if receive flow control should be issued against incoming packets (if enabled). This is a write-to-increment field. This field rolls over to 0 on overflow.<br><br>If hardware flow control or QOS is used, the host must initialize this field to the number of available buffers (one register per channel). The EMAC decrements the associated channel register for each received frame by the number of buffers in the received frame. The host must write this field with the number of buffers that have been freed due to host processing. |

### 32.5.29 MAC Control Register (MACCONTROL)

The MAC control register (MACCONTROL) is shown in [Figure 32-67](#) and described in [Table 32-68](#).

**Figure 32-67. MAC Control Register (MACCONTROL)**

**Table 32-71. FIFO Control Register (FIFOCONTROL) Field Descriptions**

| Bit  | Field        | Value | Description                                                                                                                                                                                                                                                                                                                      |
|------|--------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved     | 0     | Reserved                                                                                                                                                                                                                                                                                                                         |
| 1-0  | TXCELLTHRESH | 0-3h  | Transmit FIFO cell threshold. Indicates the number of 64-byte packet cells required to be in the transmit FIFO before the packet transfer is initiated. Packets with fewer cells will be initiated when the complete packet is contained in the FIFO. The default value is 2, but 3 is also valid. 0 and 1 are not valid values. |
|      |              | 0-1h  | Not a valid value.                                                                                                                                                                                                                                                                                                               |
|      |              | 2h    | Two 64-byte packet cells required to be in the transmit FIFO.                                                                                                                                                                                                                                                                    |
|      |              | 3h    | Three 64-byte packet cells required to be in the transmit FIFO.                                                                                                                                                                                                                                                                  |

### 32.5.33 MAC Configuration Register (MACCONFIG)

The MAC configuration register (MACCONFIG) is shown in [Figure 32-71](#) and described in [Table 32-72](#).

**Figure 32-71. MAC Configuration Register (MACCONFIG)**

|             |    |             |    |

| R/W-0     |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 32-73. Soft Reset Register (SOFTRESET) Field Descriptions**

| Bit  | Field     | Value | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|------|-----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-1 | Reserved  | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                          |
| 0    | SOFTRESET | 0     | Software reset. Writing a 1 to this bit causes the EMAC logic to be reset. Software reset occurs when the receive and transmit DMA controllers are in an idle state to avoid locking up the Configuration bus. After writing a 1 to this bit, it may be polled to determine if the reset has occurred. If a 1 is read, the reset has not yet occurred. If a 0 is read, then a reset has occurred. |
|      |           | 0     | A software reset has not occurred.                                                                                                                                                                                                                                                                                                                                                                |
|      |           | 1     | A software reset has occurred.                                                                                                                                                                                                                                                                                                                                                                    |

### 32.5.35 MAC Source Address Low Bytes Register (MACSRCADDRLO)

The MAC source address low bytes register (MACSRCADDRLO) is shown in [Figure 32-73](#) and described in [Table 32-74](#).

**Figure 32-73. MAC Source Address Low Bytes Register (MACSRCADDRLO)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 32-74. MAC Source Address Low Bytes Register (MACSRCADDRLO) Field Descriptions**

| Bit   | Field       | Value | Description                                |
|-------|-------------|-------|--------------------------------------------|
| 31-16 | Reserved    | 0     | Reserved                                   |
| 15-8  | MACSRCADDR0 | 0-FFh | MAC source address lower 8-0 bits (byte 0) |
| 7-0   | MACSRCADDR1 | 0-FFh | MAC source address bits 15-8 (byte 1)      |

### 32.5.36 MAC Source Address High Bytes Register (MACSRCADDRHI)

The MAC source address high bytes register (MACSRCADDRHI) is shown in [Figure 32-74](#) and described in [Table 32-75](#).

**Figure 32-74. MAC Source Address High Bytes Register (MACSRCADDRHI)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 32-75. MAC Source Address High Bytes Register (MACSRCADDRHI) Field Descriptions**

| Bit   | Field       | Value | Description                            |
|-------|-------------|-------|----------------------------------------|
| 31-24 | MACSRCADDR2 | 0-FFh | MAC source address bits 23-16 (byte 2) |
| 23-16 | MACSRCADDR3 | 0-FFh | MAC source address bits 31-24 (byte 3) |
| 15-8  | MACSRCADDR4 | 0-FFh | MAC source address bits 39-32 (byte 4) |
| 7-0   | MACSRCADDR5 | 0-FFh | MAC source address bits 47-40 (byte 5) |

### 32.5.37 MAC Hash Address Register 1 (MACHASH1)

The MAC hash registers allow group addressed frames to be accepted on the basis of a hash function of the address. The hash function creates a 6-bit data value (Hash\_fun) from the 48-bit destination address (DA) as follows:

$$\text{Hash\_fun}(0) = \text{DA}(0) \text{ XOR } \text{DA}(6) \text{ XOR } \text{DA}(12) \text{ XOR } \text{DA}(18) \text{ XOR } \text{DA}(24) \text{ XOR } \text{DA}(30) \text{ XOR } \text{DA}(36) \text{ XOR } \text{DA}(42);$$

$$\text{Hash\_fun}(1) = \text{DA}(1) \text{ XOR } \text{DA}(7) \text{ XOR } \text{DA}(13) \text{ XOR } \text{DA}(19) \text{ XOR } \text{DA}(25) \text{ XOR } \text{DA}(31) \text{ XOR } \text{DA}(37) \text{ XOR } \text{DA}(43);$$

$$\text{Hash\_fun}(2) = \text{DA}(2) \text{ XOR } \text{DA}(8) \text{ XOR } \text{DA}(14) \text{ XOR } \text{DA}(20) \text{ XOR } \text{DA}(26) \text{ XOR } \text{DA}(32) \text{ XOR } \text{DA}(38) \text{ XOR } \text{DA}(44);$$

$$\text{Hash\_fun}(3) = \text{DA}(3) \text{ XOR } \text{DA}(9) \text{ XOR } \text{DA}(15) \text{ XOR } \text{DA}(21) \text{ XOR } \text{DA}(27) \text{ XOR } \text{DA}(33) \text{ XOR } \text{DA}(39) \text{ XOR } \text{DA}(45);$$

$$\text{Hash\_fun}(4) = \text{DA}(4) \text{ XOR } \text{DA}(10) \text{ XOR } \text{DA}(16) \text{ XOR } \text{DA}(22) \text{ XOR } \text{DA}(28) \text{ XOR } \text{DA}(34) \text{ XOR } \text{DA}(40) \text{ XOR } \text{DA}(46);$$

$$\text{Hash\_fun}(5) = \text{DA}(5) \text{ XOR } \text{DA}(11) \text{ XOR } \text{DA}(17) \text{ XOR } \text{DA}(23) \text{ XOR } \text{DA}(29) \text{ XOR } \text{DA}(35) \text{ XOR } \text{DA}(41) \text{ XOR } \text{DA}(47);$$

This function is used as an offset into a 64-bit hash table stored in MACHASH1 and MACHASH2 that indicates whether a particular address should be accepted or not.

The MAC hash address register 1 (MACHASH1) is shown in [Figure 32-75](#) and described in [Table 32-76](#).

**Figure 32-75. MAC Hash Address Register 1 (MACHASH1)**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 32-76. MAC Hash Address Register 1 (MACHASH1) Field Descriptions**

| Bit  | Field    | Value        | Description                                                                                                                                                                   |
|------|----------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | MACHASH1 | 0-FFFF FFFFh | Least-significant 32 bits of the hash table corresponding to hash values 0 to 31. If a hash table bit is set, then a group address that hashes to that bit index is accepted. |

### 32.5.38 MAC Hash Address Register 2 (MACHASH2)

The MAC hash address register 2 (MACHASH2) is shown in [Figure 32-76](#) and described in [Table 32-77](#).

**Figure 32-76. MAC Hash Address Register 2 (MACHASH2)**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 32-77. MAC Hash Address Register 2 (MACHASH2) Field Descriptions**

| Bit  | Field    | Value        | Description                                                                                                                                                                   |
|------|----------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | MACHASH2 | 0-FFFF FFFFh | Most-significant 32 bits of the hash table corresponding to hash values 32 to 63. If a hash table bit is set, then a group address that hashes to that bit index is accepted. |

### 32.5.39 Back Off Test Register (BOFFTEST)

The back off test register (BOFFTEST) is shown in [Figure 32-77](#) and described in [Table 32-78](#).

**Figure 32-77. Back Off Random Number Generator Test Register (BOFFTEST)**

|           |    |           |    |

| R-0       |    | R-0       |    |
| 15        | 12 | 11        | 10 |
| COLLCOUNT |    | TXBACKOFF |    |
| R-0       |    | R-0       |    |

LEGEND: R = Read only; -n = value after reset

**Table 32-78. Back Off Test Register (BOFFTEST) Field Descriptions**

| Bit   | Field     | Value  | Description                                                                                                                                                                                                                                           |
|-------|-----------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-26 | Reserved  | 0      | Reserved                                                                                                                                                                                                                                              |
| 25-16 | RNDNUM    | 0-3FFh | Backoff random number generator. This field allows the Backoff Random Number Generator to be read. Reading this field returns the generator's current value. The value is reset to 0 and begins counting on the clock after the deassertion of reset. |
| 15-12 | COLLCOUNT | 0-Fh   | Collision count. These bits indicate the number of collisions the current frame has experienced.                                                                                                                                                      |
| 11-10 | Reserved  | 0      | Reserved                                                                                                                                                                                                                                              |
| 9-0   | TXBACKOFF | 0-3FFh | Backoff count. This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.  |

### 32.5.40 Transmit Pacing Algorithm Test Register (TPACETEST)

The transmit pacing algorithm test register (TPACETEST) is shown in [Figure 32-78](#) and described in [Table 32-79](#).

**Figure 32-78. Transmit Pacing Algorithm Test Register (TPACETEST)**

| 4-0  | PACEVAL  | 0-1Fh | Pacing register current value. A nonzero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to be loaded with 1Fh (31); good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to 0. When PACEVAL is nonzero, the transmitter delays four Inter Packet Gaps between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. If a transmit frame is deferred or suffers a collision, the IPG time is not stretched to four times the normal value. Transmit pacing helps reduce capture effects, which improves overall network bandwidth. |

### 32.5.41 Receive Pause Timer Register (RXPAUSE)

The receive pause timer register (RXPAUSE) is shown in [Figure 32-79](#) and described in [Table 32-80](#).

| 2-0  | MACINDEX | 0-7h  | MAC address index. All eight addresses share the upper 40 bits. Only the lower byte is unique for each address. An address is written by first writing the address number (channel) into the MACINDEX register. The upper 32 bits of the address are then written to the MACADDRHI register, which is followed by writing the lower 16 bits of the address to the MACADDRLO register. Since all eight addresses share the upper 40 bits of the address, the MACADDRHI register only needs to be written the first time. |

### 32.5.46 Transmit Channel DMA Head Descriptor Pointer Registers (TX0HDP-TX7HDP)

The transmit channel 0-7 DMA head descriptor pointer register (TX $n$ HDP) is shown in [Figure 32-84](#) and described in [Table 32-85](#).

**Figure 32-84. Transmit Channel  $n$  DMA Head Descriptor Pointer Register (TX $n$ HDP)**

LEGEND: R/W = Read/Write; - $n$  = value after reset; -x = value is indeterminate after reset

**Table 32-85. Transmit Channel  $n$  DMA Head Descriptor Pointer Register (TX $n$ HDP)  
Field Descriptions**

| Bit  | Field      | Value        | Description                                                                                                                                                                                                                                                                                                                                         |
|------|------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | TX $n$ HDP | 0-FFFF FFFFh | Transmit channel $n$ DMA Head Descriptor pointer. Writing a transmit DMA buffer descriptor address to a head pointer location initiates transmit DMA operations in the queue for the selected channel. Writing to these locations when they are nonzero is an error (except at reset). Host software must initialize these locations to 0 on reset. |

### 32.5.47 Receive Channel DMA Head Descriptor Pointer Registers (RX0HDP-RX7HDP)

The receive channel 0-7 DMA head descriptor pointer register (RX $n$ HDP) is shown in [Figure 32-85](#) and described in [Table 32-86](#).

**Figure 32-85. Receive Channel  $n$  DMA Head Descriptor Pointer Register (RX $n$ HDP)**

LEGEND: R/W = Read/Write; - $n$  = value after reset; -x = value is indeterminate after reset

**Table 32-86. Receive Channel  $n$  DMA Head Descriptor Pointer Register (RX $n$ HDP)  
Field Descriptions**

| Bit  | Field      | Value        | Description                                                                                                                                                                                                                                                                                                                                            |
|------|------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | RX $n$ HDP | 0-FFFF FFFFh | Receive channel $n$ DMA Head Descriptor pointer. Writing a receive DMA buffer descriptor address to this location allows receive DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are nonzero is an error (except at reset). Host software must initialize these locations to 0 on reset. |

### 32.5.48 Transmit Channel Completion Pointer Registers (TX0CP-TX7CP)

The transmit channel 0-7 completion pointer register (TXnCP) is shown in [Figure 32-86](#) and described in [Table 32-87](#).

**Figure 32-86. Transmit Channel  $n$  Completion Pointer Register (TX $n$ CP)**

LEGEND: R/W = Read/Write; -n = value after reset; -x = value is indeterminate after reset

**Table 32-87. Transmit Channel *n* Completion Pointer Register (TX<sub>*n*</sub>CP) Field Descriptions**

| Bit  | Field     | Value        | Description                                                                                                                                                                                                                                                           |
|------|-----------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | TX $n$ CP | 0-FFFF FFFFh | Transmit channel $n$ completion pointer register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The EMAC uses the value written to determine if the interrupt should be deasserted. |

### 32.5.49 Receive Channel Completion Pointer Registers (RX0CP-RX7CP)

The receive channel 0-7 completion pointer register (RXnCP) is shown in [Figure 32-87](#) and described in [Table 32-88](#).

**Figure 32-87. Receive Channel  $n$  Completion Pointer Register (RX $n$ CP)**

LEGEND: R/W = Read/Write; -n = value after reset; -x = value is indeterminate after reset

**Table 32-88. Receive Channel *n* Completion Pointer Register (RX<sub>*n*</sub>CP) Field Descriptions**

| Bit  | Field | Value        | Description                                                                                                                                                                                                                                                               |
|------|-------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | RXnCP | 0-FFFF FFFFh | Receive channel <i>n</i> completion pointer register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The EMAC uses the value written to determine if the interrupt should be deasserted. |

### 32.5.50 Network Statistics Registers

The EMAC has a set of statistics that record events associated with frame traffic. The statistics values are cleared to zero 38 clocks after the rising edge of reset. When the GMIIEN bit in the MACCONTROL register is set, all statistics registers (see [Figure 32-88](#)) are write-to-decrement. The value written is subtracted from the register value with the result stored in the register. If a value greater than the statistics value is written, then zero is written to the register (writing FFFF FFFFh clears a statistics location). When the GMIIEN bit is cleared, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt (STATPEND) is issued, if enabled, when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

**Figure 32-88. Statistics Register**

|    |        |   |
|----|--------|---|
| 31 |        | 0 |
|    | COUNT  |   |
|    | R/WD-0 |   |

LEGEND: R/W = Read/Write; WD = Write to decrement; -n = value after reset

#### 32.5.50.1 Good Receive Frames Register (RXGOODFRAMES)

The total number of good frames received on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 32.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 32.5.50.2 Broadcast Receive Frames Register (RXBCASTFRAMES)

The total number of good broadcast frames received on the EMAC. A good broadcast frame is defined as having all of the following:

- Any data or MAC control frame that was destined for address FF-FF-FF-FF-FF-FFh only
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 32.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 32.5.50.3 Multicast Receive Frames Register (RXMCASTFRAMES)

The total number of good multicast frames received on the EMAC. A good multicast frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any multicast address other than FF-FF-FF-FF-FF-FFh
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 32.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 32.5.50.4 Pause Receive Frames Register (RXPAUSEFRAMES)

The total number of IEEE 802.3X pause frames received by the EMAC (whether acted upon or not). A pause frame is defined as having all of the following:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08h and the opcode 0001h
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error
- Pause-frames had been enabled on the EMAC (TXFLOWEN bit is set in MACCONTROL).

The EMAC could have been in either half-duplex or full-duplex mode. See [Section 32.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 32.5.50.5 Receive CRC Errors Register (RXCRCERRORS)

The total number of frames received on the EMAC that experienced a CRC error. A frame with CRC errors is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no alignment or code error
- Had a CRC error. A CRC error is defined as having all of the following:
  - A frame containing an even number of nibbles
  - Fails the frame check sequence test

See [Section 32.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 32.5.50.6 Receive Alignment/Code Errors Register (RXALIGNCODEERRORS)

The total number of frames received on the EMAC that experienced an alignment error or code error. Such a frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had either an alignment error or a code error
  - An alignment error is defined as having all of the following:
    - A frame containing an odd number of nibbles
    - Fails the frame check sequence test, if the final nibble is ignored
  - A code error is defined as a frame that has been discarded because the EMACs MII\_RXER pin is driven with a one for at least one bit-time's duration at any point during the frame's reception.

Overruns have no effect on this statistic.

CRC alignment or code errors can be calculated by summing receive alignment errors, receive code errors, and receive CRC errors.

**32.5.50.7 Receive Oversized Frames Register (RXOVERSIZED)**

The total number of oversized frames received on the EMAC. An oversized frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was greater than RXMAXLEN in bytes
- Had no CRC error, alignment error, or code error

See [Section 32.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

**32.5.50.8 Receive Jabber Frames Register (RXJABBER)**

The total number of jabber frames received on the EMAC. A jabber frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was greater than RXMAXLEN bytes long
- Had a CRC error, alignment error, or code error

See [Section 32.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

**32.5.50.9 Receive Undersized Frames Register (RXUNDERSIZED)**

The total number of undersized frames received on the EMAC. An undersized frame is defined as having all of the following:

- Was any data frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was less than 64 bytes long
- Had no CRC error, alignment error, or code error

See [Section 32.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

**32.5.50.10 Receive Frame Fragments Register (RXFRAGMENTS)**

The total number of frame fragments received on the EMAC. A frame fragment is defined as having all of the following:

- Any data frame (address matching does not matter)
- Was less than 64 bytes long
- Had a CRC error, alignment error, or code error
- Was not the result of a collision caused by half duplex, collision based flow control

See [Section 32.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

**32.5.50.11 Filtered Receive Frames Register (RXFILTERED)**

The total number of frames received on the EMAC that the EMAC address matching process indicated should be discarded. Such a frame is defined as having all of the following:

- Was any data frame (not MAC control frame) destined for any unicast, broadcast, or multicast address
- Did not experience any CRC error, alignment error, code error
- The address matching process decided that the frame should be discarded (filtered) because it did not match the unicast, broadcast, or multicast address, and it did not match due to promiscuous mode.

To determine the number of receive frames discarded by the EMAC for any reason, sum the following statistics (promiscuous mode disabled):

- Receive fragments
- Receive undersized frames
- Receive CRC errors
- Receive alignment/code errors
- Receive jabbers
- Receive overruns
- Receive filtered frames

This may not be an exact count because the receive overruns statistic is independent of the other statistics, so if an overrun occurs at the same time as one of the other discard reasons, then the above sum double-counts that frame.

#### 32.5.50.12 Receive QOS Filtered Frames Register (RXQOSFILTERED)

The total number of frames received on the EMAC that were filtered due to receive quality of service (QOS) filtering. Such a frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- The frame destination channel flow control threshold register (RX $n$ FLOWTHRESH) value was greater than or equal to the channel's corresponding free buffer register (RX $n$ FREEBUFFER) value
- Was of length 64 to RXMAXLEN
- RXQOSEN bit is set in RXMBPENABLE
- Had no CRC error, alignment error, or code error

See [Section 32.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 32.5.50.13 Receive Octet Frames Register (RXOCTETS)

The total number of bytes in all good frames received on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 32.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 32.5.50.14 Good Transmit Frames Register (TXGOODFRAMES)

The total number of good frames transmitted on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Was any length
- Had no late or excessive collisions, no carrier loss, and no underrun

**32.5.50.15 Broadcast Transmit Frames Register (TXBCASTFRAMES)**

The total number of good broadcast frames transmitted on the EMAC. A good broadcast frame is defined as having all of the following:

- Any data or MAC control frame destined for address FF-FF-FF-FF-FF-FFh only
- Was of any length
- Had no late or excessive collisions, no carrier loss, and no underrun

**32.5.50.16 Multicast Transmit Frames Register (TXMCASTFRAMES)**

The total number of good multicast frames transmitted on the EMAC. A good multicast frame is defined as having all of the following:

- Any data or MAC control frame destined for any multicast address other than FF-FF-FF-FF-FF-FFh
- Was of any length
- Had no late or excessive collisions, no carrier loss, and no underrun

**32.5.50.17 Pause Transmit Frames Register (TXPAUSEFRAMES)**

The total number of IEEE 802.3X pause frames transmitted by the EMAC. Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect on this statistic. Pause frames sent by software are not included in this count. Since pause frames are only transmitted in full-duplex mode, carrier loss and collisions have no effect on this statistic.

Transmitted pause frames are always 64-byte multicast frames so appear in the multicast transmit frames register and 64 octet frames register statistics.

**32.5.50.18 Deferred Transmit Frames Register (TXDEFERRED)**

The total number of frames transmitted on the EMAC that first experienced deferment. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted
- Found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect on this statistic.

**32.5.50.19 Transmit Collision Frames Register (TXCOLLISION)**

The total number of times that the EMAC experienced a collision. Collisions occur under two circumstances:

- When a transmit data or MAC control frame has all of the following:
  - Was destined for any unicast, broadcast, or multicast address
  - Was any size
  - Had no carrier loss and no underrun
  - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic increments on each occasion if a frame experiences multiple collisions (and increments on late collisions).
- When the EMAC is in half-duplex mode, flow control is active, and a frame reception begins.

CRC errors have no effect on this statistic.

**32.5.50.20 Transmit Single Collision Frames Register (TXSINGLECOLL)**

The total number of frames transmitted on the EMAC that experienced exactly one collision. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect on this statistic.

**32.5.50.21 Transmit Multiple Collision Frames Register (TXMULTICOLL)**

The total number of frames transmitted on the EMAC that experienced multiple collisions. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect on this statistic.

**32.5.50.22 Transmit Excessive Collision Frames Register (TXEXCESSIVECOLL)**

The total number of frames when transmission was abandoned due to excessive collisions. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect on this statistic.

**32.5.50.23 Transmit Late Collision Frames Register (TXLATECOLL)**

The total number of frames when transmission was abandoned due to a late collision. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions that had previously required the transmission to be reattempted. The late collisions statistic dominates over the single, multiple, and excessive collisions statistics. If a late collision occurs, the frame is not counted in any of these other three statistics.

CRC errors, carrier loss, and underrun have no effect on this statistic.

**32.5.50.24 Transmit Underrun Error Register (TXUNDERRUN)**

The number of frames sent by the EMAC that experienced FIFO underrun. Late collisions, CRC errors, carrier loss, and underrun have no effect on this statistic.

**32.5.50.25 Transmit Carrier Sense Errors Register (TXCARRIERSENSE)**

The total number of frames on the EMAC that experienced carrier loss. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted)

CRC errors and underrun have no effect on this statistic.

**32.5.50.26 Transmit Octet Frames Register (TXOCTETS)**

The total number of bytes in all good frames transmitted on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Was any length
- Had no late or excessive collisions, no carrier loss, and no underrun

**32.5.50.27 Transmit and Receive 64 Octet Frames Register (FRAME64)**

The total number of 64-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was exactly 64-bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame is recorded in this statistic).

CRC errors, alignment/code errors, and overruns do not affect the recording of frames in this statistic.

**32.5.50.28 Transmit and Receive 65 to 127 Octet Frames Register (FRAME65T127)**

The total number of 65-byte to 127-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 65-bytes to 127-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

**32.5.50.29 Transmit and Receive 128 to 255 Octet Frames Register (FRAME128T255)**

The total number of 128-byte to 255-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 128-bytes to 255-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

### 32.5.50.30 Transmit and Receive 256 to 511 Octet Frames Register (FRAME256T511)

The total number of 256-byte to 511-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 256-bytes to 511-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

### 32.5.50.31 Transmit and Receive 512 to 1023 Octet Frames Register (FRAME512T1023)

The total number of 512-byte to 1023-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 512-bytes to 1023-bytes long

CRC errors, alignment/code errors, and overruns do not affect the recording of frames in this statistic.

### 32.5.50.32 Transmit and Receive 1024 to RXMAXLEN Octet Frames Register (FRAME1024TUP)

The total number of 1024-byte to RXMAXLEN-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 1024-bytes to RXMAXLEN-bytes long

CRC/alignment/code errors, underruns, and overruns do not affect frame recording in this statistic.

### 32.5.50.33 Network Octet Frames Register (NETOCTETS)

The total number of bytes of frame data received and transmitted on the EMAC. Each frame counted has all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address (address match does not matter)
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced (multiple retries are counted each time)
- Every byte received if the EMAC is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence is not counted to prevent double-counting).

Error conditions such as alignment errors, CRC errors, code errors, overruns, and underruns do not affect the recording of bytes in this statistic. The objective of this statistic is to give a reasonable indication of Ethernet utilization.

**32.5.50.34 Receive FIFO or DMA Start of Frame Overruns Register (RXSOFOVERRUNS)**

The total number of frames received on the EMAC that had either a FIFO or DMA start of frame (SOF) overrun. An SOF overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the resources to receive it (cell FIFO full or no DMA buffer available at the start of the frame).

CRC errors, alignment errors, and code errors have no effect on this statistic.

**32.5.50.35 Receive FIFO or DMA Middle of Frame Overruns Register (RXMOFOVERRUNS)**

The total number of frames received on the EMAC that had either a FIFO or DMA middle of frame (MOF) overrun. An MOF overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the resources to receive it (cell FIFO full or no DMA buffer available after the frame was successfully started - no SOF overrun).

CRC errors, alignment errors, and code errors have no effect on this statistic.

**32.5.50.36 Receive DMA Overruns Register (RXDMAOVERRUNS)**

The total number of frames received on the EMAC that had either a DMA start of frame (SOF) overrun or a DMA middle of frame (MOF) overrun. A receive DMA overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the DMA buffer resources to receive it (zero head descriptor pointer at the start or during the middle of the frame reception).

CRC errors, alignment errors, and code errors have no effect on this statistic.

## ***eFuse Controller***

---

---

---

This chapter describes the eFuse controller.

| Topic                                        | Page                        |

### 33.1 Overview

Electrically programmable fuses (eFuses) are used to configure the device after deassertion of  $\overline{\text{PORRST}}$ . The eFuse values are read and loaded into internal registers as part of the power-on-reset sequence. The eFuse values are protected with single bit error correction, double bit error detection (SECDED) codes. These fuses are programmed during the initial factory test of the device. The eFuse controller is designed so that the state of the eFuses cannot be changed once the device is packaged.

### 33.2 Introduction

The eFuse controller automatically reads the values of the eFuses and shifts them into registers during the power-on reset sequence. No action is required from the application code. However, in a safety critical application, the user code should check to see if a correctable or an uncorrectable error was detected during the reset sequence and then preform a self-test on the eFuse controller ECC logic.

### 33.3 eFuse Controller Testing

#### 33.3.1 eFuse Controller Connections to ESM

There are three connections from the eFuse controller to the Error Signaling Module (ESM). If an uncorrectable error occurs during the loading of the eFuse values after reset, a group three, channel one error and a group one channel 40 error are sent to the ESM. The group three error will cause the  $\overline{\text{ERROR}}$  pin to go low. If during the eFuse loading a correctable error occurs, only a group one channel 40 error is sent to the ESM. If an error occurs during the eFuse controller self test, then a group one channel 41 error and a group one channel 40 error are sent to the ESM. After reset, by default, the group one errors do not affect the  $\overline{\text{ERROR}}$  pin. If the software enables the appropriate bit in the appropriate ESM Influence Error Pin Set/Status Register (ESMIEPSRn) while the group one error is set, the  $\overline{\text{ERROR}}$  pin will go low.

**Table 33-1. ESM Signals Set by eFuse Controller**

| ESM Signal         | Uncorrected Load Failure | Correctable Load Error | Self Test       |                           |                              |
|--------------------|--------------------------|------------------------|-----------------|---------------------------|------------------------------|
|                    |                          |                        | eFuse Self Test | eFuse stuck at 0 Test     |                              |
|                    |                          |                        |                 | Version a: with Error pin | Version b: without Error pin |
| Group 3 Channel 1  | X                        |                        |                 | X                         |                              |
| Group 1 Channel 40 | X                        | X                      | X               |                           |                              |
| Group 1 Channel 41 |                          |                        | X               | X                         | X                            |

#### 33.3.2 Checking for eFuse Errors After Power Up

For safety critical systems, it is required that you check the status of the eFuse controller after a device reset. A suggested flow chart for checking the eFuse controller after device reset is shown in [Figure 33-1](#). Failures during the eFuse self test can be grouped into three levels of severity. Depending on the safety critical application, the error handling for each error type may be different.

##### 33.3.2.1 Class 1 Error

A class 1 error of the eFuse controller means that there was a failure during the autoload sequence. The values read from the eFuses cannot be relied on. All device operation is suspect. A class 1 error is indicated by a signal to group 3 channel 1 of the ESM. This will cause the  $\overline{\text{ERROR}}$  pin to go active low.

##### 33.3.2.2 Class 2 Errors

A class 2 error is an indication that the safety checks of the eFuse controller did not work. These are also serious errors because you can no longer guarantee that a more severe error did not occur.

### 33.3.2.3 Class 3 Error

A class 3 error indicates that there was a single bit failure reading the eFuses that was corrected by ECC bits. Proper operation is still likely, but the system is now at a higher risk for a future non-correctable error. When a correctable error occurs, ESM group 1, channel 40 will be set. In the suggested flow chart shown in [Figure 33-1](#) below, the single bit error is determined by directly reading the eFuse error status register, and not depending on the integrity of the connections between the eFuse controller and the ESM.

### 33.3.2.4 Stuck at Zero Test

The purpose of the stuck at zero test is to verify that the eFuse controller could signal the ESM if an autoload error did occur. It basically verifies the path through the eFuse controller and to the ESM. This is done by writing a special instruction to the eFuse controller boundary register, then verifying that the proper bits are set in the eFuse controller pins register. Upon successful completion of this test ESM group 1 channel 41 and ESM group 3 channel 1 will be set. This will force the **ERROR** pin low.

- Version A
  - Write boundary register (address 0xFFFF8C01C) with 0x003FC000 to set the error signals.
  - Read pins register (address 0xFFFF8C02C) and verify that bits 14, 12, 11 and 10 are set.
  - Write boundary register (address 0xFFFF8C01C) with 0x003C0000, to clear the error signals.
  - Verify that ESM group 1 channel 41 and group 3 channel 1 are set, then clear them.

If the system cannot support a test which causes the **ERROR** pin to go low, then the stuck at zero test can be modified as follows:

- Version B
  - Write boundary register (address 0xFFFF8C01C) with 0x003BC000.
  - Read pins register (address 0xFFFF8C02C) and verify that bits 14, 12, and 11 are set.
  - Write boundary register (address 0xFFFF8C01C) with 0x003C0000, to clear the error signals.
  - Verify that ESM group 1 channel 41 is set, then clear it.

This alternate method provides less test coverage because the path from the uncorrectable error signal from the eFuse controller to the ESM is not specifically tested. However, even if this path is broken, reading the five eFuse error status bits will indicate that an error occurred.

### 33.3.2.5 eFuse ECC Logic Self Test

The eFuse controller self test performs extensive validation of the ECC logic in the eFuse controller. This test should only be performed once for every device **PORRST** cycle. Perform the self test by following these steps:

- Write 0x00000258 to the self test cycles register (EFCSTCY) at address 0xFFFF8C048.
- Write 0x5362F97F to the self test signature register (EFCSTSIG) at address 0xFFFF8C04C.
- Write 0x0000200F to the boundary register at address 0xFFFF8C01C. This triggers the self test. The test takes 610 VCLK cycles to complete. The application can poll bit 15 of the pins register at address 0xFFFF8C02C to wait for the test to complete.
- Check ESM group 1 channels 40 and 41 for any errors, neither should be set.
- Verify that bits 4 to 0 of the eFuse Error Status register at address 0xFFFF8C03C are zero.

**Figure 33-1. eFuse Self Test Flow Chart**

## 33.4 eFuse Controller Registers

All registers in the eFuse Controller module are 32-bit, word-aligned; 8-bit, 16-bit and 32-bit accesses are allowed. The following table provides a quick reference to each of these registers. Specific bit descriptions are discussed in the following subsections. The base address for the control registers is 0xFFF8C000.

**Table 33-2. eFuse Controller Registers**

| Offset     | Acronym      | Register Description             | Section                        |
|------------|--------------|----------------------------------|--------------------------------|

### 33.4.1 EFC Boundary Control Register (EFCBOUND)

[Figure 33-2](#) and [Table 33-3](#) describe the EFCBOUND register. The eFuse Boundary Control Register is used to test the connections between the eFuse controller and the ESM module. The eFuse Boundary Control Register is also used to initiate an eFuse controller ECC self-test.

**Figure 33-2. EFC Boundary Control Register (EFCBOUND) [offset = 1Ch]**

### 33.4.4 EFC Self Test Cycles Register (EFCSTCY)

Figure 33-5 and Table 33-6 describe the EFCSTCY register.

**Figure 33-5. EFC Self Test Cycles Register (EFCSTCY) [offset = 48h]**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 33-6. EFC Self Test Cycles Register (EFCSTCY) Field Descriptions**

| Bit  | Name   | Description                                                                                                                                                    |
|------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–0 | Cycles | This register is used to determine the number of cycles to run the eFuse controller ECC logic self test. It is recommended to use a value of 600 (0x00000258). |

### 33.4.5 EFC Self Test Signature Register (EFCSTSIG)

Figure 33-6 and Table 33-7 describe the EFCSTSIG register.

**Figure 33-6. EFC Self Test Cycles Register (EFCSTSIG) [offset = 4Ch]**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 33-7. EFC Self Test Cycles Register (EFCSTSIG) Field Descriptions**

| Bit  | Name      | Description                                                                                                                                                                                                                                                                                                                                                                                                 |
|------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–0 | Signature | This register is used to hold the expected signature for the eFuse ECC logic self test. It is recommended to write a value of 0x5362F97F to this register and a value of 600 to the EFCSTCT register. If after running the eFuse ECC logic self test, the calculated signature does not match the expected signature in the EFCSTSIG register, then a value of 11000b is stored in the EFCERRSTAT register. |

## *Revision History*

Minor changes have been made throughout this document. [Table A-1](#) lists major changes made since the previous version of this document.

**Table A-1. Revision History**

| Chapter                            | Location                         | Additions/Modifications/Deletions                                                              |
|------------------------------------|----------------------------------|------------------------------------------------------------------------------------------------|
| Architecture                       | <a href="#">Section 2.2</a>      | Moved the Memory Organization and Exceptions sections before the Clocks section.               |
|                                    | <a href="#">Section 2.2.3.2</a>  | In fourth paragraph, corrected starting address of bank 7 ECC from 0xF0200000 to 0xF0100000.   |
|                                    | <a href="#">Table 2-10</a>       | Added VCLKA3 to the list of clock domains.                                                     |
|                                    | <a href="#">Table 2-10</a>       | Updated Special Considerations column to include list of modules that are tied to each domain. |
|                                    | <a href="#">Table 2-11</a>       | Updated Wake Up Time column.                                                                   |
|                                    | <a href="#">Table 2-30</a>       | Updated Description of CLRCLKSR[7-3] OFF bit for Value = 0 Read and Value = 1 Read and Write.  |
|                                    |                                  | Updated Description of CLRCLKSR[1-0] OFF bit for Value = 0 Read and Value = 1 Read and Write.  |
|                                    | <a href="#">Table 2-40</a>       | Updated MSTGENA and MINITGENA values to 5h for MSIENA = 1.                                     |
|                                    | <a href="#">Table 2-44</a>       | Updated Description of PLLMUL bit.                                                             |
|                                    | <a href="#">Section 2.5.1.27</a> | Deleted NOTE.                                                                                  |
|                                    | <a href="#">Figure 2-31</a>      | Updated MULMOD bits 20-16 reset value.                                                         |
|                                    | <a href="#">Table 2-45</a>       | Updated Description of SPR_AMOUNT bit.                                                         |
|                                    | <a href="#">Table 2-53</a>       | Updated Description of OUTPUT_BUFFER_LOW_EMI_MODE bit[9] to TDI and bit[10] to TDO.            |
|                                    | <a href="#">Table 2-74</a>       | Updated Description of ODPLL2, PLLDIV2, REFCLKDIV2, and PLLMUL2 bits.                          |
|                                    | <a href="#">Table 2-77</a>       | Updated Description of VCLKA4_DIV_CDDIS and VCLKA3_DIV_CDDIS bits; 0 = Enable, 1 = Disable     |
| F021 Flash Module Controller       | <a href="#">Table 5-1</a>        | Updated footnote 2. XOR of all the address and data bits.                                      |
|                                    | <a href="#">Section 5.4.2</a>    | Added OTP Memory subsection. Subsequent figure and tables renumbered.                          |
|                                    | <a href="#">Table 5-13</a>       | Deleted Flash Lock Register (FLOCK) subsection.                                                |
|                                    | <a href="#">Figure 5-8</a>       | Updated figure. Added EOFEN bit 10.                                                            |
|                                    | <a href="#">Table 5-15</a>       | Updated Description of EDACMODE bits.                                                          |
|                                    | <a href="#">Section 5.7.7</a>    | Updated third paragraph to remove bit 25.                                                      |
|                                    | <a href="#">Table 5-34</a>       | Updated Description of ILA bit. Removed reference to erase_otp command.                        |
|                                    | <a href="#">Table 5-45</a>       | Updated Description of WR_ENA bit for Value = 5h.                                              |
|                                    | <a href="#">Figure 5-41</a>      | Updated reset value of Reserved bits 31-24 to 5h.                                              |
|                                    | <a href="#">Table 5-48</a>       | Updated Value column of Reserved bits 31-20 to 050h.                                           |
|                                    | <a href="#">Figure 5-48</a>      | Updated reset value of Reserved bits 19-16 to 1.                                               |
|                                    |                                  | Updated reset value of Reserved bits 3-0 to 2h.                                                |
| Tightly-Coupled RAM (TCRAM) Module | <a href="#">Table 5-55</a>       | Updated Value column of Reserved bits 19-16 to 1.                                              |
|                                    |                                  | Updated Value column of Reserved bits 3-0 to 2h.                                               |
|                                    | <a href="#">Section 6.4</a>      | Updated last sentence to 0Ch.                                                                  |
|                                    | <a href="#">Table 6-9</a>        | Updated TEST_ENABLE bit. Enable = Ah.                                                          |

**Table A-1. Revision History (continued)**

| Chapter                                        | Location                      | Additions/Modifications/Deletions                                                                   |
|------------------------------------------------|-------------------------------|-----------------------------------------------------------------------------------------------------|
| Programmable Built-In Self-Test (PBIST) Module | <a href="#">Figure 7-2</a>    | Changed figure. Deleted FSRF1.                                                                      |

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
