

# $\pm 1^{\circ}\text{C}$ TEMPERATURE SENSOR with Series-R, n-Factor, Automatic Beta Compensation and Programmable Addressing

Check for Samples: [TMP435](#)

## FEATURES

- $\pm 1^{\circ}\text{C}$  REMOTE DIODE SENSOR
- $\pm 1^{\circ}\text{C}$  LOCAL TEMPERATURE SENSOR
- AUTOMATIC BETA COMPENSATION
- n-FACTOR CORRECTION
- PROGRAMMABLE THRESHOLD LIMITS
- TWO-WIRE/ SMBus™ SERIAL INTERFACE
- MINIMUM AND MAXIMUM TEMPERATURE MONITORS
- MULTIPLE INTERFACE ADDRESSES
- ALERT/THERM2 PIN CONFIGURATION
- DIODE FAULT DETECTION
- PIN-PROGRAMMABLE TWO-WIRE ADDRESSING

## APPLICATIONS

- LCD/ DLP®/LCOS PROJECTORS
- SERVERS
- INDUSTRIAL CONTROLLERS
- CENTRAL OFFICE TELECOM EQUIPMENT
- DESKTOP AND NOTEBOOK COMPUTERS
- STORAGE AREA NETWORKS (SAN)
- INDUSTRIAL AND MEDICAL EQUIPMENT
- PROCESSOR/FPGA TEMPERATURE MONITORING

## DESCRIPTION

The TMP435 is a remote temperature sensor monitor with a built-in local temperature sensor. The remote temperature sensor diode-connected transistors are typically low-cost, NPN- or PNP-type transistors or diodes that are an integral part of microcontrollers, microprocessors, or FPGAs.

Remote accuracy is  $\pm 1^{\circ}\text{C}$  for multiple IC manufacturers, with no calibration needed. The two-wire serial interface accepts SMBus write byte, read byte, send byte, and receive byte commands to program the alarm thresholds and to read temperature data.

The TMP435 includes beta compensation (correction), series resistance cancellation, programmable non-ideality factor, programmable resolution, programmable threshold limits, minimum and maximum temperature monitors, wide remote temperature measurement range (up to  $+150^{\circ}\text{C}$ ), diode fault detection, a temperature alert function, and pin-programmable two-wire addressing using 3-state logic.

The TMP435 is available in an MSOP-10 package.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

DLP is a registered trademark of Texas Instruments.

SMBus is a trademark of Intel Corporation.

All other trademarks are the property of their respective owners.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

### PACKAGE INFORMATION<sup>(1)</sup>

PRODUCT	DESCRIPTION	TWO-WIRE ADDRESS	PACKAGE-LEAD	PACKAGE DESIGNATOR	PACKAGE MARKING
TMP435	Remote Junction Temperature Sensor	Pin-programmable	MSOP-10	DGS	DTPI

(1) For the most current package and ordering information see the Package Option Addendum at the end of this document, or see the TI web site at [www.ti.com](http://www.ti.com).

### ABSOLUTE MAXIMUM RATINGS<sup>(1)</sup>

Over operating free-air temperature range, unless otherwise noted.

		TMP435	UNIT
Power Supply, $V_S$		+7.0	V
Input Voltage	Pins 2, 3, 4, 5 and 8 only	-0.5 to $V_S + 0.5$	V
	Pins 7, 9, and 10 only	-0.5 to 7	V
Input Current		10	mA
Operating Temperature Range		-55 to +127	°C
Storage Temperature Range		-60 to +130	°C
Junction Temperature ( $T_J$ max)		+150	°C
ESD Rating	Human Body Model (HBM)	4000	V
	Charged Device Model (CDM)	1000	V
	Machine Model (MM)	200	V

(1) Stresses above these ratings may cause permanent damage. Exposure to absolute maximum conditions for extended periods may degrade device reliability. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those specified is not implied.

## ELECTRICAL CHARACTERISTICS

At  $T_A = -40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$  and  $V_S = 2.7\text{V}$  to  $5.5\text{V}$ , unless otherwise noted.

## PIN ASSIGNMENTS

TMP435		DESCRIPTION
NO.	NAME	
1	V+	Positive supply (2.7V to 5.5V)
2	DXP	Positive connection to remote temperature sensor
3	DXN	Negative connection to remote temperature sensor
4	A0	Address pin 0
5	A1	Address pin 1
6	GND	Ground
7	THERM	Thermal flag, active low, open-drain; requires pull-up resistor to V+
8	ALERT/THERM2	Alert (reconfigurable as second thermal flag), active low, open-drain; requires pull-up resistor to V+
9	SDA	Serial data line for SMBus, open-drain; requires pull-up resistor to V+
10	SCL	Serial clock line for SMBus, open-drain; requires pull-up resistor to V+

## APPLICATION INFORMATION

The TMP435 (two-channel) is a digital temperature sensor that combines a local die temperature measurement channel and a remote junction temperature measurement channel in a single package. This device is two-wire- and SMBus interface-compatible, and is specified over a temperature range of  $-40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$ . The TMP435 contains multiple registers for holding configuration information, temperature measurement results, temperature comparator maximum/minimum limits, and status information. User-programmed high and low temperature limits stored in the TMP435 can be used to trigger an over/under temperature alarm ( $\overline{\text{ALERT}}$ ) on local and remote temperatures. Additional thermal limits can be programmed into the TMP435 and used to trigger another flag ( $\overline{\text{THERM}}$ ) that can be used to initiate a system response to rising temperatures.

For proper remote temperature sensing operation, the TMP435 requires only a transistor connected between DXP and DXN.

The SCL and SDA interface pins require pull-up resistors as part of the communication bus, while  $\overline{\text{ALERT}}$  and  $\overline{\text{THERM}}$  are open-drain outputs that also need pull-up resistors.  $\overline{\text{ALERT}}$  and  $\overline{\text{THERM}}$  may be shared with other devices if desired for a wired-OR implementation. A  $0.1\mu\text{F}$  power-supply bypass capacitor is recommended for good local bypassing. See Figure 13 for a typical configuration.

### Beta Compensation

Previous generations of remote junction temperature sensors were operated by controlling the emitter current of the sensing transistor. However, examination of the physics of a transistor shows that  $V_{\text{BE}}$  is actually a function of the collector current. If beta is independent of the collector current, then  $V_{\text{BE}}$  may be calculated from the emitter current. In earlier generations of processors that contained PNP transistors connected to these temperature sensors, controlling the emitter current provided acceptable temperature measurement results. At 90nm process geometry and below, the beta factor continues to decrease and the premise that it is independent of collector current becomes less certain.

To manage this increasing temperature measurement error, the TMP435 controls the collector current instead of the emitter current. The TMP435 automatically detects and chooses the correct range depending on the beta factor of the external transistor. This auto-ranging is performed at the beginning of each temperature conversion in order to

correct for any changes in the beta factor as a result of temperature variation. The device can operate a PNP transistor with a beta factor as low as 0.1. See the [Beta Compensation Configuration Register](#) section for further information.

### Series Resistance Cancellation

Series resistance in an application circuit that typically results from printed circuit board (PCB) trace resistance and remote line length is automatically cancelled by the TMP435, preventing what would otherwise result in a temperature offset. A total of up to  $1\text{k}\Omega$  of series line resistance is cancelled by the TMP435 if beta correction is disabled and up to  $300\Omega$  of series line resistance is canceled if beta correction is enabled, eliminating the need for additional characterization and temperature offset correction. See the two *Remote Temperature Error vs Series Resistance* typical characteristic curves (Figure 7 and Figure 8) for details on the effect of series resistance on sensed remote temperature error.

### Differential Input Capacitance

The TMP435 can tolerate differential input capacitance of up to  $2200\text{pF}$  with minimal change in temperature error. The effect of capacitance on sensed remote temperature error is illustrated in Figure 9 and Figure 10, *Remote Temperature Error vs Differential Capacitance*. See the [Filtering](#) section for suggested component values where filtering unwanted coupled signals is needed.

### Temperature Measurement Data

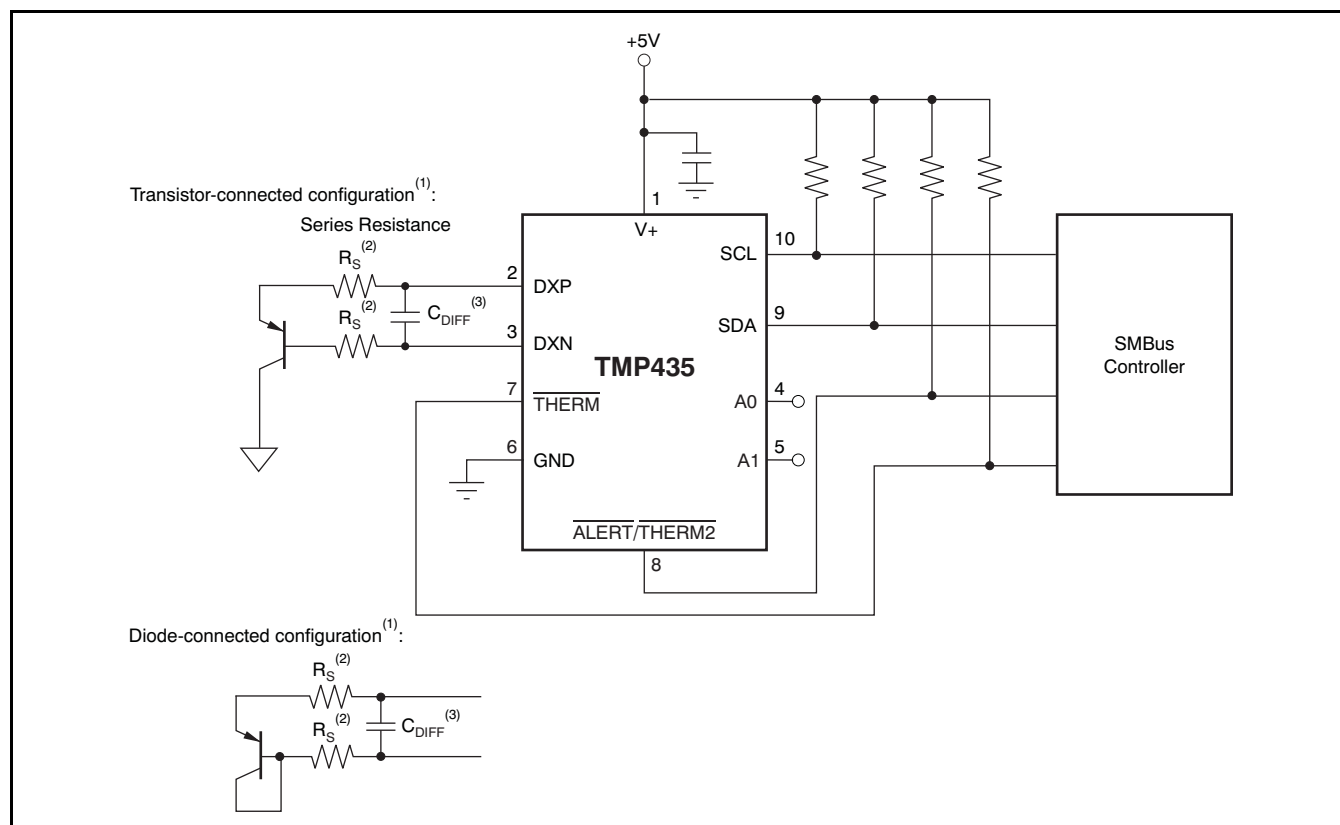

Temperature measurement data are taken over a default range of  $0^{\circ}\text{C}$  to  $+127^{\circ}\text{C}$  for both local and remote locations. However, measurements from  $-55^{\circ}\text{C}$  to  $+150^{\circ}\text{C}$  can be made both locally and remotely by reconfiguring the TMP435 for the extended temperature range, as described in this section. Temperature data resulting from conversions within the default measurement range are represented in binary form, as shown in Table 1, *Standard Binary* column. Note that any temperature below  $0^{\circ}\text{C}$  results in a data value of zero (00h). Likewise, temperatures above  $+127^{\circ}\text{C}$  result in a value of 127 (7Fh). The device can be set to measure over an extended temperature range by changing bit 2 (RANGE) of Configuration Register 1 from low to high. The change in measurement range and data format from standard binary to extended binary occurs at the next temperature conversion.

For data captured in the extended temperature range configuration, an offset of 64 (40h) is added to the standard binary value, as shown in [Table 1, Extended Binary](#) column. This configuration allows measurement of temperatures as low as  $-64^{\circ}\text{C}$ , and as high as  $+191^{\circ}\text{C}$ ; however, most temperature-sensing diodes only measure with the range of  $-55^{\circ}\text{C}$  to  $+150^{\circ}\text{C}$ .

Additionally, the TMP435 is rated only for ambient local temperatures ranging from  $-40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$ . Parameters in the [Absolute Maximum Ratings](#) table must be observed.

Both local and remote temperature data use two bytes for data storage. The high byte stores the temperature with  $1^{\circ}\text{C}$  resolution. The second or low byte stores the decimal fraction value of the temperature and allows a higher measurement resolution, as shown in [Table 2](#).

The measurement resolution for both the local and remote channels is  $0.0625^{\circ}\text{C}$ , and cannot be adjusted.

- (1) Diode-connected configuration provides better settling time. Transistor-connected configuration provides better series resistance cancellation.
- (2)  $R_S$  (optional) should be  $< 1\text{k}\Omega$  in most applications. Selection of  $R_S$  depends on specific application; see [Filtering](#) section.
- (3)  $C_{\text{DIFF}}$  (optional) should be  $< 2200\text{pF}$  in most applications. Selection of  $C_{\text{DIFF}}$  depends on specific application; see [Filtering](#) section and [Figure 9, Remote Temperature Error vs Differential Capacitance](#).

(1) NA = Not applicable; register is write- or read-only.

(2) X = Indeterminate state.

(3) X = Undefined. Writing any value to this register initiates a software reset; see the [Software Reset](#) section.

## Pointer Register

**Figure 14** shows the internal register structure of the TMP435. The 8-bit Pointer Register is used to address a given data register. The Pointer Register identifies which of the data registers should respond to a read or write command on the two-wire bus. This register is set with every write command. A write command must be issued to set the proper value in the Pointer Register before executing a read command. **Table 3** describes the pointer address of the registers available in the TMP435. The power-on reset (POR) value of the Pointer Register is 00h (0000 0000b).

## Temperature Registers

The TMP435 has four 8-bit registers that hold temperature measurement results. Both the local channel and the remote channel have a high byte register that contains the most significant bits (MSBs) of the temperature analog-to-digital converter (ADC) result and a low byte register that contains the least significant bits (LSBs) of the temperature ADC result. The local channel high byte address for the TMP435 is 00h; the local channel low byte address is 15h. The remote channel high byte is at address 01h; the remote channel low byte address is 10h. These registers are read-only and are updated by the ADC each time a temperature measurement is completed.

The TMP435 contains circuitry to assure that a low byte register read command returns data from the same analog-to-digital (A/D) conversion as the immediately preceding high byte read command. This assurance remains valid only until another register is read. For proper operation, the high byte of a temperature register should be read first. The low byte register should be read in the next read command. The low byte register may be left unread if the LSBs are not needed. Alternatively, the temperature registers may be read as a 16-bit register by using a single two-byte read command from address 00h for the local channel result, or from address 01h for the remote channel result (23h for the second remote channel result). The high byte is output first, followed by the low byte. Both bytes of this read operation are from the same A/D conversion. The power-on reset value of both temperature registers is 00h.

## Limit Registers

The TMP435 has registers for setting comparator limits for both the local and remote measurement channels. These registers have read and write capability. The High and Low Limit Registers for both channels span two registers, as do the temperature registers. The local temperature high limit is set by writing the high byte to pointer address 0Bh and writing the low byte to pointer address 16h, or by using a single two-byte write command (high byte first) to pointer address 0Bh.

The local temperature high limit is obtained by reading the high byte from pointer address 05h and the low byte from pointer address 16h, or by using a two-byte read command from pointer address 05h. The power-on reset value of the local temperature high limit is 55h/00h (+85°C in standard temperature mode; +21°C in extended temperature mode).

Similarly, the local temperature low limit is set by writing the high byte to pointer address 0Ch and writing the low byte to pointer address 17h, or by using a single two-byte write command to pointer address 0Ch. The local temperature low limit is read by reading the high byte from pointer address 06h and the low byte from pointer address 17h, or by using a two-byte read from pointer address 06h. The power-on reset value of the local temperature low limit register is 00h/00h (0°C in standard temperature mode; –64°C in extended mode).

The remote temperature high limit for the TMP435 is set by writing the high byte to pointer address 0Dh and writing the low byte to pointer address 13h, or by using a two-byte write command to pointer address 0Dh. The remote temperature high limit is obtained by reading the high byte from pointer address 07h and the low byte from pointer address 13h, or by using a two-byte read command from pointer address 07h. The power-on reset value of the Remote Temperature High Limit Register is 55h/00h (+85°C in standard temperature mode; +21°C in extended temperature mode).

The remote temperature low limit for the TMP435 is set by writing the high byte to pointer address 0Eh and writing the low byte to pointer address 14h, or by using a two-byte write to pointer address 0Eh. The remote temperature low limit is read by reading the high byte from pointer address 08h and the low byte from pointer address 14h, or by using a two-byte read from pointer address 08h. The power-on reset value of the Remote Temperature Low Limit Register is 00h/00h (0°C in standard temperature mode; –64°C in extended mode).

The TMP435 also has a THERM limit register for both the local and the remote channels. These are 8-bit registers and allow for THERM limits set to 1°C resolution. The local channel THERM limit is set by writing to pointer address 20h. The remote channel THERM limit is set by writing to pointer address 19h.

The local channel THERM limit is obtained by reading from pointer address 20h; the remote channel THERM limit is read by reading from pointer address 19h. The power-on reset value of the THERM limit registers is 55h (+85°C in standard temperature mode; +21°C in extended temperature mode). The THERM limit comparators also have hysteresis. The hysteresis of both comparators is set by writing to pointer address 21h. The hysteresis value is obtained by reading from pointer address 21h. The value in the Hysteresis Register is an unsigned number (always positive). The power-on reset value of this register is 0Ah (+10°C).

Whenever changing between standard and extended temperature ranges, be aware that the temperatures stored in the temperature limit registers are **NOT** automatically reformatted to correspond to the new temperature range format. These values must be reprogrammed in the appropriate binary or extended binary format.

## Status Register

The TMP435 has a Status Register to report the state of the temperature comparators. [Table 4](#) shows the Status Register bits. The Status Register is read-only and is read by reading from pointer address 02h.

The BUSY bit reads as '1' if the ADC is making a conversion. It reads as '0' if the ADC is not converting.

The OPEN bit reads as '1' if the remote transistor was detected as open since the last read of the Status Register. The OPEN status is only detected when the ADC attempts to convert a remote temperature.

The RTHRM bit reads as '1' if the remote temperature has exceeded the remote THERM limit and remains greater than the remote THERM limit less the value in the shared Hysteresis Register; see [Figure 20](#).

The LTHRM bit reads as '1' if the local temperature has exceeded the local THERM limit and remains greater than the local THERM limit less the value in the shared Hysteresis Register; see [Figure 20](#).

**Table 4. TMP435 Status Register Format**

TMP435 STATUS REGISTER (Read = 02h, Write = NA)								
BIT #	D7	D6	D5	D4	D3	D2	D1	D0
BIT NAME	BUSY	LHIGH	LLOW	RHIGH	RLOW	OPEN	RTHRM	LTHRM
POR VALUE	0 <sup>(1)</sup>	0	0	0	0	0	0	0

- (1) The BUSY bit changes to '1' almost immediately (<< 100µs) following power-up, as the TMP435 begins the first temperature conversion. It is high whenever the TMP435 is converting a temperature reading.

The LHIGH and RHIGH bit values depend on the state of the  $\overline{\text{AL/TH}}$  bit in the Configuration Register. If the  $\overline{\text{AL/TH}}$  bit is '0', the LHIGH bit reads as '1' if the local high limit was exceeded since the last clearing of the Status Register. The RHIGH bit reads as '1' if the remote high limit was exceeded since the last clearing of the Status Register. If the  $\overline{\text{AL/TH}}$  bit is '1', the remote high limit and the local high limit are used to implement a  $\overline{\text{THERM2}}$  function. LHIGH reads as '1' if the local temperature has exceeded the local high limit and remains greater than the local high limit less the value in the Hysteresis Register.

The RHIGH bit reads as '1' if the remote temperature has exceeded the remote high limit and remains greater than the remote high limit less the value in the Hysteresis Register.

The LLOW and RLOW bits are not affected by the  $\overline{\text{AL/TH}}$  bit. The LLOW bit reads as '1' if the local low limit was exceeded since the last clearing of the Status Register. The RLOW bit reads as '1' if the remote low limit was exceeded since the last clearing of the Status Register.

The values of the LLOW, RLOW, and OPEN (as well as LHIGH and RHIGH when  $\overline{\text{AL/TH}}$  is '0') are latched and read as '1' until the Status Register is read or a device reset occurs. These bits are cleared by reading the Status Register, provided that the condition causing the flag to be set no longer exists. The values of BUSY, LTHRM, and RTHRM (as well as LHIGH and RHIGH when  $\overline{\text{ALERT/THERM2}}$  is '1') are not latched and are not cleared by reading the Status Register. They always indicate the current state, and are updated appropriately at the end of the corresponding A/D conversion. Clearing the Status Register bits does not clear the state of the  $\overline{\text{ALERT}}$  pin; an SMBus alert response address command must be used to clear the  $\overline{\text{ALERT}}$  pin.

The TMP435 NORs, LHIGH, LLOW, RHIGH, RLOW, and OPEN, so a status change for any of these flags from '0' to '1' automatically causes the  $\overline{\text{ALERT}}$  pin to go low (only applies when the  $\overline{\text{ALERT/THERM2}}$  pin is configured for ALERT mode).

## Configuration Register 1

Configuration Register 1 sets the temperature range, controls shutdown mode, and determines how the  $\overline{\text{ALERT/THERM2}}$  pin functions. This Configuration Register is set by writing to pointer address 09h and read by reading from pointer address 03h.

The MASK bit (bit 7) enables or disables the  $\overline{\text{ALERT}}$  pin output if  $\overline{\text{ALERT/THERM2}} = 0$ . If  $\overline{\text{ALERT/THERM2}} = 1$  then the MASK bit has no effect. If MASK is set to '0', the  $\overline{\text{ALERT}}$  pin goes low when one of the temperature measurement channels exceeds its high or low limits for the chosen number of consecutive conversions. If the MASK bit is set to '1', the TMP435 retains the  $\overline{\text{ALERT}}$  pin status, but the  $\overline{\text{ALERT}}$  pin does not go low.

The shutdown (SD) bit (bit 6) enables or disables the temperature measurement circuitry. If  $\text{SD} = 0$ , the TMP435 converts continuously at the rate set in the conversion rate register. When SD is set to '1', the TMP435 immediately stops converting and enters a shutdown mode. When SD is set to '0' again, the TMP435 resumes continuous conversions. A single conversion can be started when  $\text{SD} = 1$  by writing to the One-Shot Register.

The  $\overline{\text{AL/TH}}$  bit (bit 5) controls whether the  $\overline{\text{ALERT}}$  pin functions in  $\overline{\text{ALERT}}$  mode or  $\overline{\text{THERM2}}$  mode. If  $\overline{\text{ALTH}} = 0$ , the  $\overline{\text{ALERT}}$  pin operates as an interrupt pin. In this mode, the  $\overline{\text{ALERT}}$  pin goes low after the set number of consecutive out-of-limit temperature measurements occur.

If  $\overline{\text{AL/TH}} = 1$ , the  $\overline{\text{ALERT/THERM2}}$  pin implements a THERM function ( $\overline{\text{THERM2}}$ ). In this mode,  $\overline{\text{THERM2}}$  functions similar to the  $\overline{\text{THERM}}$  pin except that the local high limit and remote high limit registers are used for the thresholds.  $\overline{\text{THERM2}}$  goes low when either RHIGH or LHIGH is set.

The temperature range is set by configuring bit 2 of Configuration Register 1. Setting this bit low configures the TMP435 for the standard measurement range (0°C to +127°C); temperature conversions are stored in the standard binary format. Setting bit 2 high configures the TMP435 for the extended measurement range (–55°C to +150°C); temperature conversions are stored in the extended binary format (see Table 1).

The remaining bits of Configuration Register 1 are reserved and must always be set to '0'. The power-on reset value for this register is 00h. Table 5 summarizes the bits of Configuration Register 1.

**Table 5. Configuration Register 1 Bit Descriptions**

<b>CONFIGURATION REGISTER 1</b> (Read = 03h, Write = 09h, POR = 00h)			
<b>BIT</b>	<b>NAME</b>	<b>FUNCTION</b>	<b>POWER-ON RESET VALUE</b>
7	MASK	0 = ALERT Enabled 1 = ALERT Masked	0
6	SD	0 = Run 1 = Shut Down	0
5	$\overline{\text{AL}}/\text{TH}$	0 = ALERT Mode 1 = THERM Mode	0
4, 3	Reserved	—	0
2	Temperature Range	0 = 0°C to +127°C 1 = -55°C to +150°C	0
1, 0	Reserved	—	0

**Configuration Register 2**

Configuration Register 2 (pointer address 1Ah) controls which temperature measurement channels are enabled and whether the external channels have the resistance correction feature enabled or not.

The RC bit enables the resistance correction feature for the external temperature channels. If RC = '1', series resistance correction is enabled; if RC = '0', resistance correction is disabled. Resistance correction should be enabled for most applications. However, disabling the resistance correction may yield slightly improved temperature measurement noise performance, and reduce conversion time by about 50%, which could lower power consumption when conversion rates of two per second or less are selected.

The LEN bit enables the local temperature measurement channel. If LEN = '1', the local channel is enabled; if LEN = '0', the local channel is disabled.

The REN bit enables external temperature measurement channel 1 (connected to pins 1 and 2.) If REN = '1', the external channel is enabled; if REN = '0', the external channel is disabled.

The temperature measurement sequence is local channel, external channel 1, shutdown, and delay (to set conversion rate, if necessary). The sequence starts over with the local channel. If any of the channels are disabled, they are skipped in the sequence. [Table 6](#) summarizes the bits of Configuration Register 2.

**Table 6. Configuration Register 2 Bit Descriptions**

<b>CONFIGURATION REGISTER 2</b> (Read/Write = 1A, POR = 1Ch)			
<b>BIT</b>	<b>NAME</b>	<b>FUNCTION</b>	<b>POWER-ON RESET VALUE</b>
7, 6, 5	Reserved	—	0
4	REN	0 = External channel 1 disabled 1 = External channel 1 enabled	1
3	LEN	0 = Local channel disabled 1 = Local channel enabled	1
2	RC	0 = Resistance correction disabled 1 = Resistance correction enabled	1
1, 0	Reserved	—	0

## Conversion Rate Register

The Conversion Rate Register (pointer address 0Ah) controls the rate at which temperature conversions are performed. This register adjusts the idle time between conversions but not the conversion timing itself, thereby allowing the TMP435 power dissipation to be balanced with the temperature register update rate. [Table 7](#) shows the conversion rate options and corresponding current consumption.

## Beta Compensation Configuration Register

If the Beta Compensation Configuration Register is set to '1xxx' (beta correction enabled) for a given channel at the beginning of each temperature conversion, the TMP435 automatically detects if the sensor is diode-connected or GND collector-connected, selects the proper beta range, and measures the sensor temperature appropriately.

If the Beta Compensation Configuration Register is set to '0111' (beta correction disabled) for a given channel, the automatic detection is bypassed and the temperature is measured assuming a diode-connected sensor. A PNP transistor may continue to be GND collector-connected in this mode, but no beta compensation factor is applied. When the beta correction is set to '0111' or the sensor is diode-connected (base shorted to collector), the  $n$ -factor used by the TMP435 is 1.008. When the beta correction configuration is set to '1xxx' (beta correction enabled) and the sensor is GND collector-connected (PNP collector to ground), the  $n$ -factor used by the TMP435 is 1.000. [Table 8](#) shows the read value for the selected beta ranges and the appropriate  $n$ -factor used for each conversion.

**Table 7. Conversion Rate Register**

CONVERSION RATE REGISTER (Read = 04h, Write = 0Ah, POR = 07h)									AVERAGE I <sub>Q</sub> (TYP) ( $\mu$ A)

0110	Manually selected range 6 (2.4 < beta < 150)	1.000	93ms
0111	Manually disabled beta correction	1.008	93ms

## ***n*-Factor Correction Register**

The TMP435 allows for a different *n*-factor value to be used for converting remote channel measurements to temperature. The remote channel uses sequential current excitation to extract a differential  $V_{BE}$  voltage measurement to determine the temperature of the remote transistor. Equation 1 relates this voltage and temperature.

$$V_{BE2} - V_{BE1} = \frac{nkT}{q} \ln\left(\frac{I_2}{I_1}\right) \quad (1)$$

The value *n* in Equation 1 is a characteristic of the particular transistor used for the remote channel. When the beta compensation configuration is set to '0111' (beta compensation disabled) or the sensor is diode-connected (base shorted to collector), the *n*-factor used by the TMP435 is 1.008. When the beta compensation configuration is set to '1000' (beta compensation enabled) and the sensor is GND collector-connected (PNP collector to ground), the *n*-factor used by the TMP435 is 1.000. If the *n*-factor used for the temperature conversion does not match the characteristic of the sensor, then temperature offset is observed. The value in the *n*-Factor Correction Register may be used to adjust the effective *n*-factor according to Equation 2 and Equation 3 for disabled beta compensation or a diode-connected sensor. Equation 4 and Equation 5 may be used for enabled beta compensation and a GND collector-connected sensor.

$$n_{eff} = \frac{1.008 \times 300}{300 - N_{ADJUST}} \quad (2)$$

$$N_{ADJUST} = 300 - \frac{300 \times 1.008}{n_{eff}} \quad (3)$$

$$n_{eff} = \frac{1.000 \times 300}{300 - N_{ADJUST}} \quad (4)$$

$$N_{ADJUST} = 300 - \frac{300 \times 1.000}{n_{eff}} \quad (5)$$

The *n*-correction value must be stored in twos-complement format, yielding an effective data

range from –128 to +127. Table 9 shows the *n*-factor range for both 1.008 and 1.000. For the TMP435, the *n*-correction value may be written to and read from pointer address 18h. The register power-on reset value is 00h, thus having no effect unless written to.

**Table 9. *n*-Factor Range**

N <sub>ADJUST</sub>			n-FACTOR
BINARY	HEX	DECIMAL	
01111111	7F	127	1.747977

10000000	80	–128	0.706542

## **Software Reset**

The TMP435 may be reset by writing any value to Pointer Register FCh. This action restores the power-on reset state to all of the TMP435 registers as well as abort any conversion in process and clear the ALERT and THERM pins.

The TMP435 also supports reset via the two-wire general call address (00000000). The TMP435 acknowledges the general call address and responds to the second byte. If the second byte is 00000110, the TMP435 executes a software reset. The TMP435 does not respond to other values in the second byte.

## Consecutive Alert Register

The value in the Consecutive Alert Register (address 22h) determines how many consecutive out-of-limit measurements must occur on a measurement channel before the ALERT/THERM2 or the THERM signal is activated. The value in this register does not affect bits in the Status Register. Values of one, two, three, or four consecutive conversions can be selected; one conversion is the default. This function allows additional filtering for the ALERT/THERM2 or the THERM pin. Table 13 shows the consecutive alert bits. For bit descriptions, refer to Table 10.

**Table 10. Consecutive Alert Register Bit Descriptions**

BIT NAME			NUMBER OF CONSECUTIVE OUT-OF-LIMIT MEASUREMENTS (ALERT/THERM)
CALT2/CTH2	CALT1/CTH1	CALT0/CTH0	
0	0	0	1
0	0	1	2
0	1	1	3
1	1	1	4

## Therm Hysteresis Register

The THERM Hysteresis Register, shown in Table 12, stores the hysteresis value used for the THERM pin alarm function and for the ALERT/THERM2 pin when the AL/TH is 1. This register must be programmed with a value that is less than the Local Temperature High Limit Register value, Remote Temperature High Limit Register value, Local THERM Limit Register value, or Remote THERM Limit Register value; otherwise, the respective temperature comparator

does not trip on the measured temperature falling edges. Allowable hysteresis values are shown in Table 11. The default hysteresis value is 10°C, whether the device is operating in the standard or extended mode setting.

## Identification Registers

The TMP435 allows for the two-wire bus controller to query the device for manufacturer and device IDs to enable the device for software identification of the device at the particular two-wire bus address. The manufacturer ID is obtained by reading from pointer address FEh. The TMP435 returns 55h for the manufacturer code. The device ID is obtained by reading from pointer address FDh. The TMP435 returns 31h for the device ID (see Table 3). These registers are read-only.

**Table 11. Allowable THERM Hysteresis Values**

TEMPERATURE (°C)	THERM HYSTERESIS VALUE

## Bus Overview

The TMP435 is SMBus interface-compatible. In SMBus protocol, the device that initiates the transfer is called a *master*, and the devices controlled by the master are *slaves*. The bus must be controlled by a master device that generates the serial clock (SCL), controls the bus access, and generates the START and STOP conditions.

To address a specific device, a START condition is initiated. START is indicated by pulling the data line (SDA) from a high to low logic level while SCL is high. All slaves on the bus shift in the slave address byte, with the last bit indicating whether a read or write operation is intended. During the ninth clock pulse, the slave being addressed responds to the master by generating an Acknowledge and pulling SDA low.

Data transfer is then initiated and sent over eight clock pulses followed by an Acknowledge bit. During data transfer SDA must remain stable while SCL is high, because any change in SDA while SCL is high is interpreted as a control signal.

Once all data have been transferred, the master generates a STOP condition. STOP is indicated by pulling SDA from low to high, while SCL is high.

## Serial Interface

The TMP435 operates only as a slave device on either the two-wire bus or the SMBus. Connections to either bus are made via the open-drain I/O lines, SDA and SCL. The SDA and SCL pins feature integrated spike suppression filters and Schmitt triggers to minimize the effects of input spikes and bus noise. The TMP435 supports the transmission protocol for fast (1kHz to 400kHz) and high-speed (1kHz to 3.4MHz) modes. All data bytes are transmitted MSB first.

## Serial Bus Address

To communicate with the TMP435, the master must first address slave devices via a slave address byte. The slave address byte consists of seven address bits, and a direction bit indicating the intent of executing a read or write operation.

The address of the TMP435 is 4Ch (1001100b).

## Two-Wire Interface Slave Device Addresses

The TMP435 supports nine slave device addresses and is available in two different fixed serial interface addresses.

The A1 and A0 pins, as summarized in [Table 14](#), set the slave device address for the TMP435.

**Table 14. Two-Wire Addresses**

A0	A1	ADDRESS
0	0	1001 100
0	1	1001 101
1	0	1001 110
1	1	1001 111
0	Z	1001 000
Z	0	1001 001
1	Z	1001 010
Z	1	1001 011
Z	Z	0110 111

## Read/Write Operations

Accessing a particular register on the TMP435 is accomplished by writing the appropriate value to the Pointer Register. The value for the Pointer Register is the first byte transferred after the slave address byte with the R/W bit low. Every write operation to the TMP435 requires a value for the Pointer Register (see [Figure 16](#)).

When reading from the TMP435, the last value stored in the Pointer Register by a write operation is used to determine which register is read by a read operation. To change the register pointer for a read operation, a new value must be written to the Pointer Register. This transaction is accomplished by issuing a slave address byte with the R/W bit low, followed by the Pointer Register byte. No additional data are required. The master can then generate a START condition and send the slave address byte with the R/W bit high to initiate the read command. See [Figure 17](#) for details of this sequence. If repeated reads from the same register are desired, it is not necessary to continually send the Pointer Register bytes, because the TMP435 retains the Pointer Register value until it is changed by the next write operation. Note that register bytes are sent MSB first, followed by the LSB.

## TIMING DIAGRAMS

The TMP435 is two-wire and SMBus-compatible. Figure 15 to Figure 19 describe the various operations on the TMP435. Bus definitions are given below. Parameters for Figure 15 are defined in Table 15.

**Bus Idle:** Both SDA and SCL lines remain high.

**Start Data Transfer:** A change in the state of the SDA line, from high to low, while the SCL line is high, defines a START condition. Each data transfer is initiated with a START condition.

**Stop Data Transfer:** A change in the state of the SDA line from low to high while the SCL line is high defines a STOP condition. Each data transfer terminates with a STOP or a repeated START condition.

**Data Transfer:** The number of data bytes transferred between a START and a STOP condition is not limited and is determined by the master device. The receiver acknowledges the transfer of data.

**Acknowledge:** Each receiving device, when addressed, is obliged to generate an Acknowledge bit. A device that acknowledges must pull down the SDA line during the Acknowledge clock pulse in such a way that the SDA line is stable low during the high period of the Acknowledge clock pulse. Setup and hold times must be taken into account. On a master receive, data transfer termination can be signaled by the master generating a Not-Acknowledge on the last byte that has been transmitted by the slave.

**Figure 15. Two-Wire Timing Diagram**

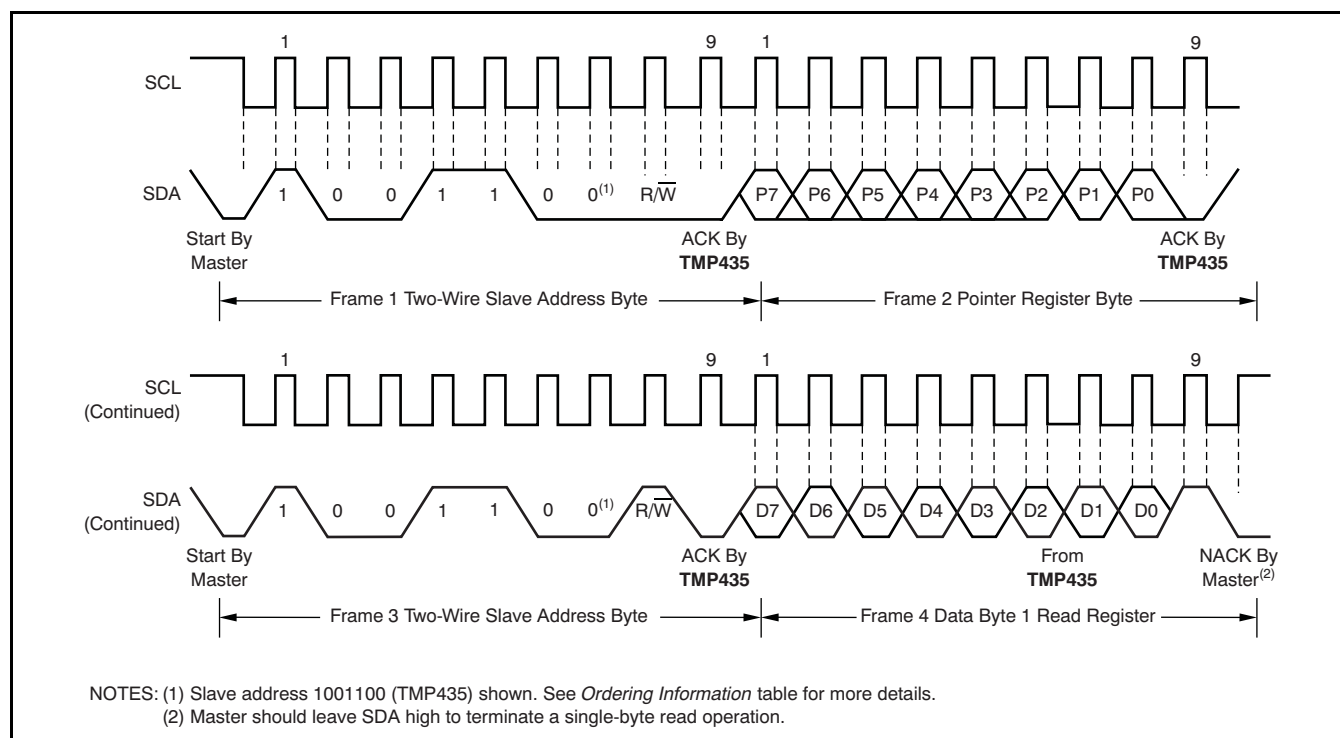

**Table 15. Timing Diagram Definitions for Figure 15**

PARAMETER		FAST MODE		HIGH-SPEED MODE		UNITS
		MIN	MAX	MIN	MAX	
SCL Operating Frequency	$f_{(SCL)}$	0.001	0.4	0.001	3.4	MHZ
Bus Free Time Between STOP and START Condition	$t_{(BUF)}$	600		160		ns
Hold time after repeated START condition. After this period, the first clock is generated.	$t_{(HDSTA)}$	100		100		ns
Repeated START Condition Setup Time	$t_{(SUSTA)}$	100		100		ns
STOP Condition Setup Time	$t_{(SUSTO)}$	100		100		ns
Data Hold Time	$t_{(HDDAT)}$	0 <sup>(1)</sup>		0 <sup>(2)</sup>		ns
Data Setup Time	$t_{(SUDAT)}$	100		10		ns
SCL Clock LOW Period	$t_{(LOW)}$	1300		160		ns
SCL Clock HIGH Period	$t_{(HIGH)}$	600		60		ns
Clock/Data Fall Time	$t_F$		300		160	ns
Clock/Data Rise Time	$t_R$		300		160	ns
for SCLK $\leq$ 100kHz			1000			ns

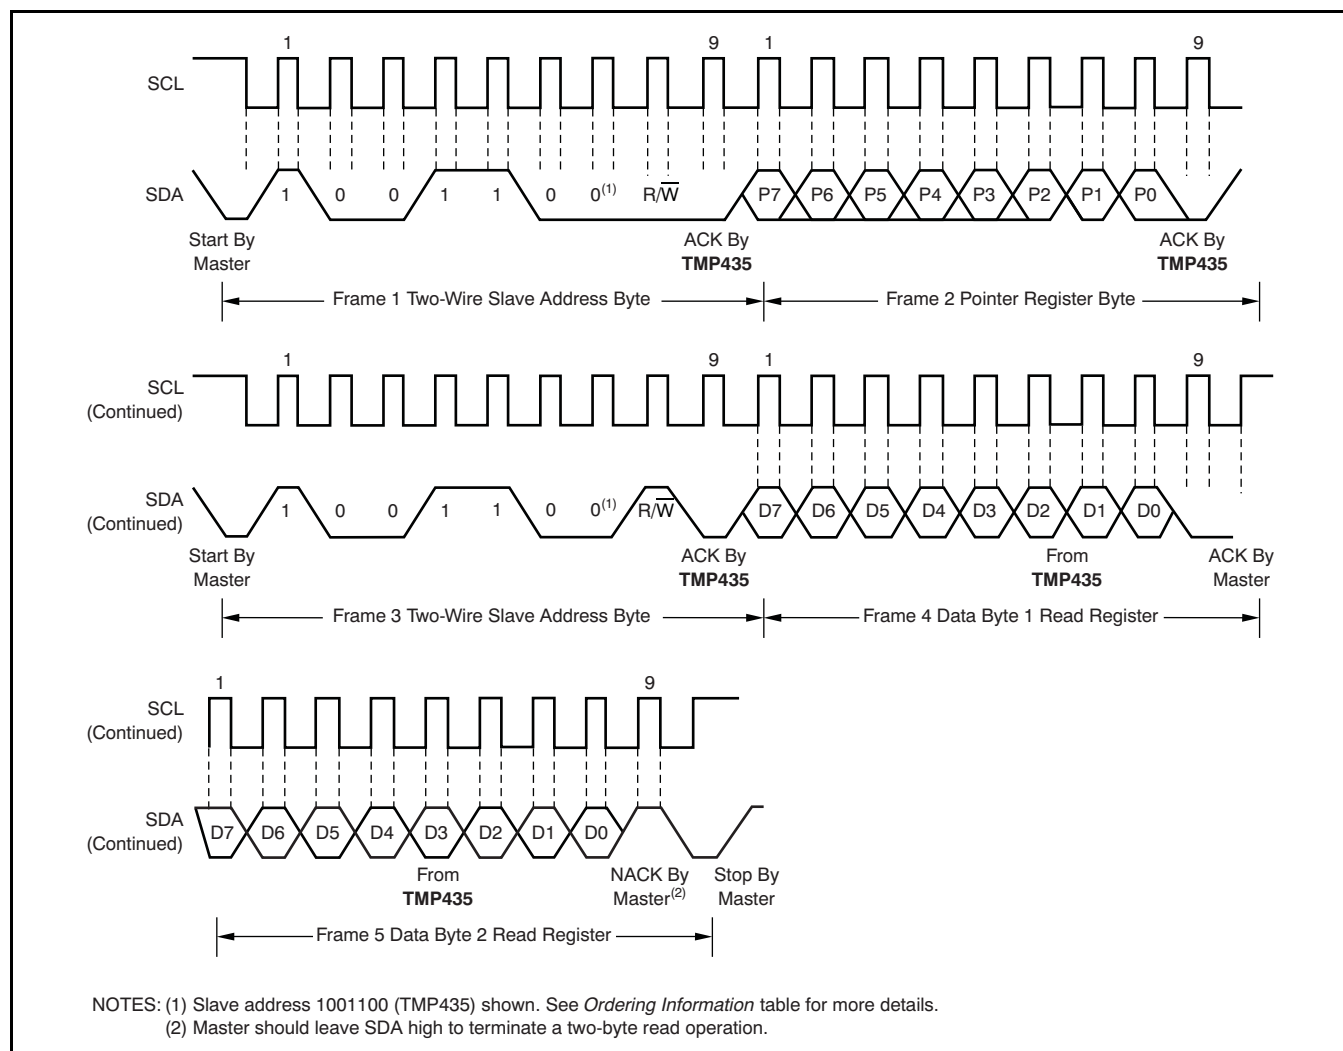

- (1) For cases with fall time of SCL less than 20ns and/or the rise time or fall time of SDA less than 20ns, the hold time should be greater than 20ns.
- (2) For cases with fall time of SCL less than 10ns and/or the rise or fall time of SDA less than 10ns, the hold time should be greater than 10ns.

**Figure 19. Timing Diagram for SMBus ALERT**

## High-Speed Mode

In order for the two-wire bus to operate at frequencies above 400kHz, the master device must issue a High-speed mode (Hs-mode) master code (00001XXX) as the first byte after a START condition to switch the bus to high-speed operation. The TMP435 does not acknowledge this byte, but switches the input filters on SDA and SCL and the output filter on SDA to operate in Hs-mode, allowing transfers at up to 3.4MHz. After the Hs-mode master code has been issued, the master transmits a two-wire slave address to initiate a data transfer operation. The bus continues to operate in Hs-mode until a STOP condition occurs on the bus. Upon receiving the STOP condition, the TMP435 switches the input and output filter back to fast-mode operation.

## Timeout Function

The serial interface of the TMP435 resets if either SCL or SDA are held low for 32ms (typical) between a START and STOP condition. If the TMP435 is holding the bus low, it releases the bus and waits for a START condition.

## THERM and ALERT/THERM2

The TMP435 has two pins dedicated to alarm functions, the THERM and ALERT/THERM2 pins. Both pins are open-drain outputs that each require a pull-up resistor to V+. These pins can be wire-ORed together with other alarm pins for system monitoring of multiple sensors. The THERM pin provides a thermal interrupt that cannot be software disabled. The ALERT pin is intended for use as an earlier warning interrupt, and can be software disabled, or masked. The ALERT/THERM2 pin can also be configured for use as THERM2, a second THERM pin (Configuration Register: AL/TH bit = 1). The default setting configures pin 6 for the TMP435 to function as ALERT (AL/TH = 0).

The THERM pin asserts low when either the measured local or remote temperature is outside of the temperature range programmed in the corresponding Local/Remote THERM Limit Register. The THERM temperature limit range can be programmed with a wider range than that of the limit registers, which allows ALERT to provide an earlier warning than THERM. The THERM alarm resets automatically when the measured temperature returns to within the THERM temperature limit range

minus the hysteresis value stored in the THERM Hysteresis Register. The allowable values of hysteresis are shown in [Table 11](#). The default hysteresis is 10°C. When the ALERT/THERM2 pin is configured as a second thermal alarm (Configuration Register: bit 7 = x, bit 5 = 1), it functions the same as THERM, but uses the temperatures stored in the Local/Remote Temperature High Limit Registers to set its comparison range.

When ALERT/THERM2 is configured as ALERT (Configuration Register: bit 7 = 0, bit 5 = 0), the pin asserts low when either the measured local or remote temperature violates the range limit set by the corresponding Local/Remote Temperature High/Low Limit Registers. This alert function can be configured to assert only if the range is violated a specified number of consecutive times (1, 2, 3, or 4). The consecutive violation limit is set in the Consecutive Alert Register. False alerts that occur as a result of environmental noise can be prevented by requiring consecutive faults. ALERT also asserts low if the remote temperature sensor is open-circuit. When the MASK function is enabled (Configuration Register 1: bit 7 = 1), ALERT is disabled (that is, masked). ALERT resets when the master reads the device address, as long as the condition that caused the alert no longer persists, and the Status Register has been reset.

## SMBus Alert Function

The TMP435 supports the SMBus Alert function. When pin 6 is configured as an alert output, the ALERT pin of the TMP435 may be connected as an SMBus Alert signal. When a master detects an alert condition on the ALERT line, the master sends an SMBus Alert command (00011001) on the bus. If the ALERT pin of the TMP435 is active, the device acknowledges the SMBus Alert command and responds by returning its slave address on the SDA line. The eighth bit (LSB) of the slave address byte indicates whether the temperature exceeding one of the temperature high limit settings or falling below one of the temperature low limit settings caused the alert condition. This bit is high if the temperature is greater than or equal to one of the temperature high limit settings; this bit is low if the temperature is less than one of the temperature low limit settings. See [Figure 20](#) for details of this sequence.

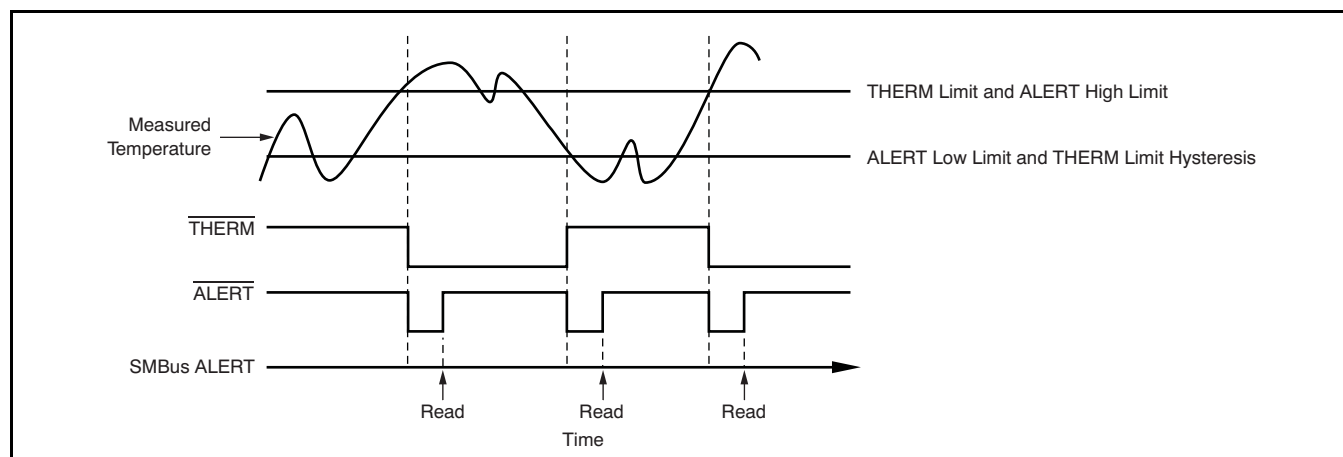

Figure 20. SMBus Alert Timing Diagram

If multiple devices on the bus respond to the SMBus Alert command, arbitration during the slave address portion of the SMBus Alert command determines which device must clear its `alert` status. If the TMP435 wins the arbitration, its `ALERT` pin becomes inactive at the completion of the SMBus Alert command. If the TMP435 loses the arbitration, the `ALERT` pin remains active.

### Shutdown Mode (SD)

The TMP435 shutdown mode allows the user to save maximum power by shutting down all device circuitry other than the serial interface, reducing current consumption to typically less than 3µA; see the typical characteristic graph, *Shutdown Quiescent Current vs Supply Voltage* (Figure 6). Shutdown mode is enabled when the SD bit of the Configuration Register 1 is high; the device shuts down immediately, aborting the current conversion. When SD is low, the device maintains a continuous conversion state.

### Sensor Fault

The TMP435 can sense a fault at the DXP input that results from incorrect diode connection or an open circuit. The detection circuitry consists of a voltage comparator that trips when the voltage at DXP exceeds  $(V+) - 0.6V$  (typical). The comparator output is continuously checked during a conversion. If a fault is detected, the last valid measured temperature is used for the temperature measurement result, the OPEN bit (Status Register, bit 2) is set high, and, if the alert function is enabled, `ALERT` asserts low.

When not using the remote sensor with the TMP435, the DXP and DXN inputs must be connected together to prevent meaningless fault warnings.

### Under-Voltage Lockout

The TMP435 senses when the power-supply voltage has reached a minimum voltage level for the ADC to function. The detection circuitry consists of a voltage comparator that enables the ADC after the power supply ( $V+$ ) exceeds 2.45V (typical). The comparator output is continuously checked during a conversion. The TMP435 does not perform a temperature conversion if the power supply is not valid. The last valid measured temperature is used for the temperature measurement result.

### General Call Reset

The TMP435 supports reset via the Two-Wire General Call address 00h (0000 0000b). The TMP435 acknowledges the General Call address and responds to the second byte. If the second byte is 06h (0000 0110b), the TMP435 executes a software reset. This software reset restores the power-on reset state to all TMP435 registers, aborts any conversion in progress, and clears the `ALERT` and `THERM` pins. The TMP435 takes no action in response to other values in the second byte.

### Filtering

Remote junction temperature sensors are usually implemented in a noisy environment. Noise is frequently generated by fast digital signals and if not filtered properly will induce errors that can corrupt temperature measurements. The TMP435 has a built-in 65kHz filter on the inputs of DXP and DXN to minimize the effects of noise. However, a differential low-pass filter can help attenuate unwanted coupled signals. Exact component values are application-specific. It is also recommended that the capacitor value remains between 0pF to 2200pF with a series resistance less than 1kΩ.

## Remote Sensing

The TMP435 is designed to be used with either discrete transistors or substrate transistors built into processor chips and ASICs. Either NPN- or PNP-type transistors can be used, as long as the base-emitter junction is used as the remote temperature sense. NPN transistors must be diode-connected. PNP transistors can either be transistor- or diode-connected (see [Figure 13](#)).

Errors in remote temperature sensor readings are typically the consequence of the ideality factor and current excitation used by the TMP435 versus the manufacturer-specified operating current for a given transistor. Some manufacturers specify a high-level and low-level current for the temperature-sensing substrate transistors. The TMP435 uses 6μA for  $I_{LOW}$  and 120μA for  $I_{HIGH}$ . The device allows for different  $n$ -factor values; see the [N-Factor Correction Register](#) section.

The ideality factor ( $n$ ) is a measured characteristic of a remote temperature sensor diode as compared to an ideal diode. The ideality factor for the TMP435 is trimmed to be 1.008. For transistors whose ideality factor does not match the TMP435, [Equation 6](#) can be used to calculate the temperature error. Note that for the equation to be used correctly, actual temperature (°C) must be converted to Kelvin (K).

$$T_{ERR} = \left( \frac{n - 1.008}{1.008} \right) \times [273.15 + T(^{\circ}C)]$$

Where:

- $n$  = Ideality factor of remote temperature sensor
- $T(^{\circ}C)$  = actual temperature
- $T_{ERR}$  = Error in TMP435 reading because  $n \neq 1.008$
- Degree delta is the same for °C and K

(6)

For  $n = 1.004$  and  $T(^{\circ}C) = 100^{\circ}C$ :

$$T_{ERR} = \left( \frac{1.004 - 1.008}{1.008} \right) \times (273.15 + 100^{\circ}C)$$

$$T_{ERR} = 1.48^{\circ}C \quad (7)$$

If a discrete transistor is used as the remote temperature sensor with the TMP435, the best accuracy can be achieved by selecting the transistor according to the following criteria:

1. Base-emitter voltage > 0.25V at 6μA, at the highest sensed temperature.
2. Base-emitter voltage < 0.95V at 120μA, at the lowest sensed temperature.

3. Base resistance < 100Ω.

4. Tight control of  $V_{BE}$  characteristics indicated by small variations in  $h_{FE}$  (that is, 50 to 150).

Based on these criteria, two recommended small-signal transistors are the 2N3904 (NPN) or 2N3906 (PNP).

## Measurement Accuracy and Thermal Considerations

The temperature measurement accuracy of the TMP435 depends on the remote and/or local temperature sensor being at the same temperature as the system point being monitored. Clearly, if the temperature sensor is not in good thermal contact with the part of the system being monitored, then there is a delay in the response of the sensor to a temperature change in the system. For remote temperature sensing applications using a substrate transistor (or a small, SOT23 transistor) placed close to the device being monitored, this delay is usually not a concern.

The local temperature sensor inside the TMP435 monitors the ambient air around the device. The thermal time constant for the TMP435 is approximately two seconds. This constant implies that if the ambient air changes quickly by 100°C, it would take the TMP435 about 10 seconds (that is, five thermal time constants) to settle to within 1°C of the final value. In most applications, the TMP435 package is in thermal contact with the PCB, as well as subjected to forced airflow. The accuracy of the measured temperature directly depends on how accurately the PCB and forced airflow temperatures represent the temperature that the TMP435 is measuring. Additionally, the internal power dissipation of the TMP435 can cause the temperature to rise above the ambient or PCB temperature. The internal power dissipated as a result of exciting the remote temperature sensor is negligible because of the small currents used. For a 5.5V supply and maximum conversion rate of eight conversions per second, the TMP435 dissipates 1.82mW ( $PD_{IQ} = 5.5V \times 330\mu A$ ). If both the  $\overline{ALERT}/\overline{THERM2}$  and  $\overline{THERM}$  pins are each sinking 1mA, an additional power of 0.8mW is dissipated ( $PD_{OUT} = 1mA \times 0.4V + 1mA \times 0.4V = 0.8mW$ ). Total power dissipation is then 2.62mW ( $PD_{IQ} + PD_{OUT}$ ) and, with a  $\theta_{JA}$  of 165°C/W, causes the junction temperature to rise approximately 0.432°C above the ambient.

## Layout Considerations

Remote temperature sensing on the TMP435 measures very small voltages using very low currents; therefore, noise at the IC inputs must be minimized. Most applications using the TMP435 have high digital content, with several clocks and logic level transitions creating a noisy environment. Layout should adhere to the following guidelines:

1. Place the TMP435 as close to the remote junction sensor as possible.
2. Route the DXP and DXN traces next to each other and shield them from adjacent signals through the use of ground guard traces, as shown in Figure 21. If a multilayer PCB is used, bury these traces between ground or  $V_{DD}$  planes to shield them from extrinsic noise sources. 5 mil (0,127 mm) PCB traces are recommended.
3. Minimize additional thermocouple junctions caused by copper-to-solder connections. If these junctions are used, make the same number and approximate locations of copper-to-solder connections in both the DXP and DXN connections to cancel any thermocouple effects.
4. Use a 0.1 $\mu$ F local bypass capacitor directly between the V+ and GND of the TMP435. Figure 22 shows the suggested bypass capacitor placement for the TMP435. Minimize filter capacitance between DXP and DXN to 2200pF or less for optimum measurement performance. This capacitance includes any cable capacitance between the remote temperature sensor and TMP435.
5. If the connection between the remote temperature sensor and the TMP435 is less than 8 inches (20,32 cm), use a twisted-wire pair connection. Beyond 8 inches, use a twisted, shielded pair with the shield grounded as close to the TMP435 as possible. Leave the remote sensor connection end of the shield wire open to avoid ground loops and 60Hz pickup.
6. Thoroughly clean and remove all flux residue in and around the pins of the TMP435 to avoid

temperature offset readings as a result of leakage paths between DXP or DXN and GND, or between DXP or DXN and V+.

Note: Use 5mil (.005in, or 0,127mm) traces with 5mil spacing.

## REVISION HISTORY

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Original (March, 2010) to Revision A	Page
• Changed typo in second paragraph of <a href="#">Beta Compensation Configuration Register</a> section to clarify state of beta correction .....	17
• Corrected POR value in <a href="#">Table 7</a> .....	17
• Corrected <a href="#">Equation 7</a> .....	26

## PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead/Ball Finish (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
TMP435ADGSR	ACTIVE	VSSOP	DGS	10	2500	Green (RoHS & no Sb/Br)	CU NIPDAU   CU NIPDAUAG	Level-2-260C-1 YEAR	-40 to 125	DTPI	<a href="#">Samples</a>
TMP435ADGST	ACTIVE	VSSOP	DGS	10	250	Green (RoHS & no Sb/Br)	CU NIPDAU   CU NIPDAUAG	Level-2-260C-1 YEAR	-40 to 125	DTPI	<a href="#">Samples</a>

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBsolete:** TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
